di L. 65.000 (paesi extraeuropei)
Data ..... Firma .....

second outburst observed with the Voyager 1 UVS (JD 2445272). These data pertain to SS Cyg at maximum light and represent a sum of on-axis spectra having a total integration time of 17,280 s. The IUE data for SS Cyg are from A. V. Holm (personal communication) and were obtained on 14–15 June 1978. The ground-based data are from Oke and Wade[5], obtained on 11 July 1977. All three observations are from long duration outbursts, however, as they are from different outbursts, small adjustments in flux had to be made to get the three segments to match at the overlap points. These adjustments in log F_λ were +0.05 and −0.05 for the IUE and ground-based data respectively. The Voyager far-UV data for U Gem also represent a sum of maximum light, on-axis spectra, with a total integration time of 23,040 s. The IUE data are from Panek and Holm[6] obtained on 10 October 1980. Although representing different outbursts, no adjustments were made between the Voyager and IUE data.

Examination of the Lyman continuum region ($\lambda < 912$ Å) of SS Cyg and U Gem shows no evidence of any extreme-UV emission. Specifically, in the 540–740 Å band Voyager observations establish a 3σ upper limit on the mean flux of 2×10^{-13} erg cm^{-2} s^{-1} Å^{-1} for both stars (see Fig. 2). In the case of SS Cyg such a limit is not entirely unanticipated, as interstellar neutral hydrogen column densities of the order of 10^{20} cm^{-2} have been deduced from soft X-ray observations[7,8]. Our upper limit for the U Gem outburst is, however, of more interest as a considerably lower H I column density has been inferred for U Gem[8]. We can use our result to establish a lower limit on the H I column density in the direction of U Gem. IUE observations of U Gem[6] during quiescence have established that shortward of 2,000 Å the energy distribution of U Gem approximates that of a 30,000 K white dwarf. Such an object will contribute little to the total extreme-UV flux at 640 Å, thus any flux at these wavelengths arises from the region producing the quiescent soft X-rays. Extrapolation of this soft X-ray distribution into the extreme-UV region is very uncertain. Depending on the extrapolation used, neutral hydrogen column densities in excess of 10^{17} to 10^{18} cm^{-2} will be sufficient to reduce the expected extreme-UV flux below our limit of detection. Soft X-ray fluxes, however, are observed to increase dramatically during the outburst phase[8] so that the extreme-UV flux can also be expected to show a corresponding increase. In such conditions, somewhat larger hydrogen column densities would be necessary to satisfy our observed EUV upper limit.

Table 1 Outburst observations of SS Cyg and U Gem

Star	JD of UVS observation (2440000.0+)	Voyager spacecraft and data rate*	JD of visual rise to maximum† (2440000+)	$m_{v_{max}}$†	Approximate duration of outburst† (days)
SS Cyg	4,372.4–4,374.0	1,L	4373	8.4	17
	4,382.7–4,389.0	2,L,H			
SS Cyg	5,278.5–5,282.6	1, L	5272	8.4	18
U Gem	5,397.7–5,402.4	1, L	5393	9.1	17

* 1 = Voyager 1; 2 = Voyager 2. L, 1 spectrum/576 s; H, 1 spectrum/3.84 s.
† From AAVSO (American Association of Variable Star Observers) light curve charts supplied by Mattei (personal communication).

A comparison of the relative far-UV flux distributions of SS Cyg and U Gem indicate that except for strong hydrogen Lyman series absorption in SS Cyg, the two distributions are statistically indistinguishable. If the UVS far-UV distribution is to be represented by a power law of the form $F_\lambda \propto \lambda^\alpha$, α must be -0.5 ± 0.5. This is significantly different from the exponent, ~ -2.3, measured in near-UV (IUE) region. The shape of the distribution does not, however, suggest a power law. Both stars show a noticeable change in slope near 1,000 Å. Note that the change in slopes seen in Fig. 2 is not an artefact of the Voyager flux calibration. Examination of sources having true power law spectra, such as some very hot O subdwarfs and central stars of planetary nebula, shows that Voyager fluxes produce no discontinuity or change of slope in the power laws which characterize IUE and ground-based fluxes. The most likely cause of this change in slope is line blocking in the dwarf nova disk. A comparison of these flux distributions with those of other objects observed with the Voyager UVS indicate that they are very similar in slope and shape to intermediate temperature (~50,000 K) subdwarfs or white dwarfs. In particular, this intercomparison of flux distributions reveals that any object with a suggested effective temperature in excess of ~70,000 K yielded a much steeper slope in the far-UV than either SS Cyg or U Gem. Because SS Cyg and U Gem are at radically different inclinations[9] (38° and 67° respectively) it is unlikely that this absence of evidence for higher temperatures ($T \gtrsim 50{,}000$ K) could be due

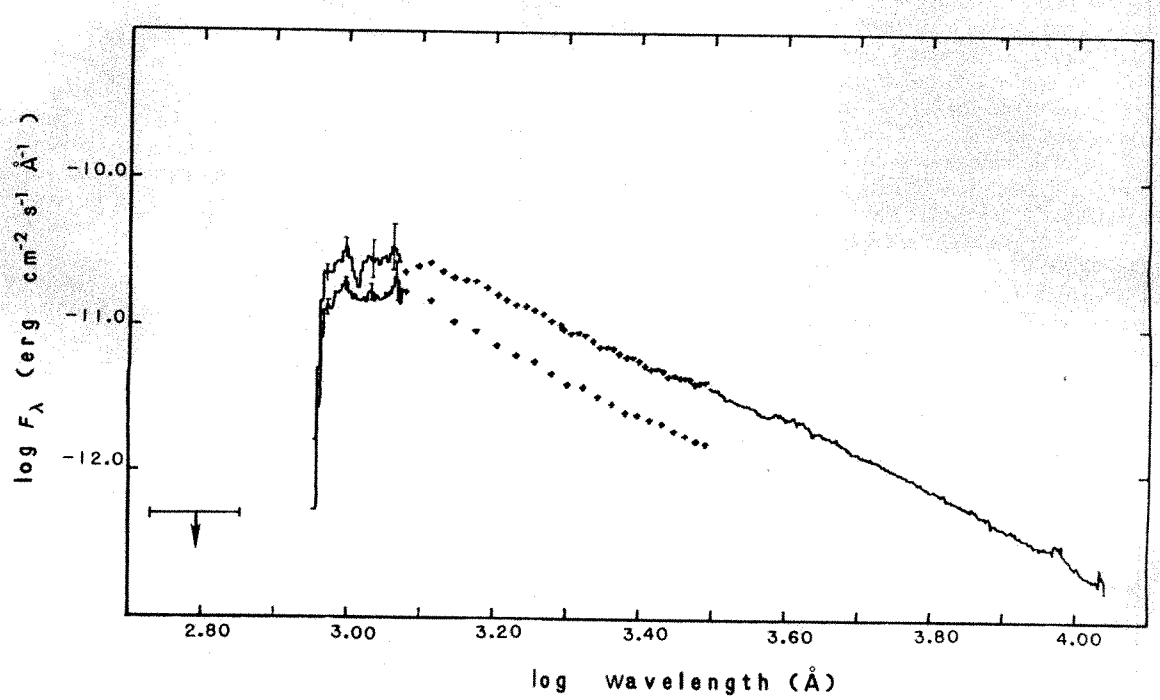

Fig. 2 Composite energy distributions for SS Cyg (upper) and U Gem (lower). The Voyager data (histogram, $\pm 2\sigma$ error bars indicated) are from JD 2445278-83 (SS Cyg) and JD 2445398–402 (U Gem). The IUE data (crosses) are from JD 2443673/74 (SS Cyg, A. V. Holm, personal communication) and JD 2444522 (U Gem[6]). The ground-based data for SS Cyg (solid line) is from JD 2443335 (ref. 5).

to occultation effects. Thus, the inner disk in these dwarf novae must be radically different in structure from that predicted by theory (see ref. 10). Such a change in slope could be due to a breakdown of the thin disk approximation. If the disk became thick it would radiate as a rapidly rotating star[10]. This would satisfy the observed far-UV energy distribution (Fig. 2) and could explain the absence of evidence for a boundary layer through occultation effects and/or reprocessing of radiation.

With the outburst flux distribution for SS Cyg (Fig. 2) a bolometric luminosity can be computed. The shape of the far-UV distribution suggests that only a small amount of energy ($\lesssim 15\%$) is intrinsically emitted shortward of 912 Å. We find that the luminosity for SS Cyg in outburst is $1.3 \pm 0.3 \times 10^{34}$ erg s^{-1} ($\sim 3.3\ L_{\odot}$), assuming a distance of 50 pc (ref. 11). Similar arguments can be made for U Gem. However, the absence of adequate ground-based data makes the resultant luminosity very uncertain. Assuming a 3,000–10,000 Å distribution similar to that of SS Cyg, a luminosity of $1.5 \pm 0.5 \times 10^{34}$ erg s^{-1} is derived for a distance of 75 pc (ref. 12).

As discussed earlier, the only difference between the SS Cyg and U Gem far-UV flux distributions is the presence of Lyman series hydrogen absorption in SS Cyg. [Note neither SS Cyg nor U Gem show any suggestion of He II (specifically 1,085 Å) absorption.] The identification of this line as Lyβ and not O VI is based on the results of a division of the SS Cyg distribution by that of U Gem. This division revealed additional weak absorptions at Lyγ and Lyδ. The data from the earlier outburst observed in SS Cyg with Voyager also show Lyβ absorption. Although in this outburst the line is quite variable in strength. We postulate that most of the observed hydrogen absorption in SS Cyg originates in a wind. Such winds have been observed in other dwarf novae of low inclination[13]. The absence of wind lines in U Gem is also consistent with this model. Interstellar Lyβ is also a likely contributor to the absorption in SS Cyg. However, the observed variability of the feature suggests that it cannot be the principle source of the line.

The principal results from the Voyager UVS investigation of SS Cyg and U Gem in outburst can be summarized as follows. The far-UV light curve confirms the earlier observation of a delay in the rise of flux at shorter wavelengths relative to that occurring at longer wavelengths in the early stages of an outburst. The flux distribution in the far-UV is significantly flatter ($F_{\lambda} \propto \lambda^{-0.5 \pm 0.5}$) than that in the near-UV (IUE) region. No extreme-UV emission was detected in either SS Cyg or U Gem and the shape of their far-UV flux distributions suggest that little intrinsic extreme-UV flux is emitted. A bolometric luminosity of $1.3 \pm 0.3 \times 10^{34}$ erg s^{-1} is derived for SS Cyg in outburst ($d = 50$ pc). A similar luminosity, $1.5 \pm 0.5 \times 10^{34}$ ergs s^{-1}, is deduced for U Gem ($d = 75$ pc). No evidence is found for any significant area of the inner disk/boundary layer region with a temperature in excess of ~50,000 K. The far-UV flux distribution can be best represented by a high gravity ($\log g \sim 6$–8) intermediate temperature ($T_{\rm eff} \sim 50{,}000$ K) stellar atmosphere. These results argue for a significantly different inner disk/boundary layer structure than current theory predicts. Further observations of cataclysmic variables, simultaneous with observations for IUE and ground-based telescopes, are planned.

Upper limit on solar interior rotation

Martin Woodard

Center for Astrophysics and Space Sciences, University of California, San Diego, La Jolla, California 92093, USA

The power spectrum of solar total irradiance (flux) variations from the Active Cavity Radiometer Irradiance Monitor (ACRIM) on the Solar Maximum Mission (SMM) spacecraft shows individual 5-min *p*-mode oscillations[1,2] of spherical harmonic degree $l = 0$–2 and radial order $n = 16$–26. An *m*-state splitting analysis based on the widths of the (n, l) multiplets in the spectrum of ACRIM data yields a mean (sidereal) interior rotation rate between 0 and 2.2 times the observed 0.456-μHz equatorial surface rate, consistent with the rapid rotation rate originally claimed by Claverie *et al.*[3] based on a (controversial) splitting interpretation of the these 5-min modes seen in line-of-sight velocity. Rotationally split *p*- and *g*- and *f*-modes have been identified in the temporal power spectrum of the limb-darkening data of Bos and Hill[4], and from these splittings two internal rotation curves[5,6] have been deduced which imply a solar gravitational quadrupole moment J_2 large enough to spoil the precise agreement between general relativity and observations of planetary motion. The splitting of the low-l 5-min *p*-modes implied by these curves is inconsistent with the upper limit derived here, and the reported conflict with einsteinian theory, is therefore, premature.

In this analysis I assume that the fluid angular velocity within the Sun has a radial dependence of the form $\mathbf{\Omega} = \Omega(r)\hat{z}$. The axis $\hat{z}$ is known from surface motion. For a rotation law of this form, the frequency of a free-oscillation mode depends on the quantum numbers (nlm) of the mode as[7]:

$$\nu_{nlm} = \nu_{nl} + m\Delta_{nl} \tag{1}$$

where Δ_{nl}, defined in an inertial frame, is an integral over radius of $\Omega(r)$ times a weighting function. Explicit expressions for the weighting functions, or splitting kernels, are given in ref. 7. (Other sources of splitting, such as a magnetic field, will be ignored in this analysis.) For rotation curves which are suitably smooth functions of r, the low-l 5-min *p*-mode splitting is adequately approximated by the expression[8]

$$\Delta = \int_0^R \frac{\Omega(r)}{2\pi} \frac{\mathrm{d}r}{c(r)} \Big/ \int_0^R \frac{\mathrm{d}r}{c(r)} \tag{2}$$

in which $c(r)$ is the sound speed at radius r. I further assume that the modes are excited independently and isotropically, and that the mean energy per (nlm) mode depends only on frequency, in accordance with the overall distribution of power in peaks of different l as observed in the power spectrum of both the Nice data[8,9] and the ACRIM data.

The present conclusions come from measurements of the width of several $l = 0$ and 1 peaks near the maximum of the 5-min mode excitation envelope (~3,100 μHz). The $l = 2$ peaks were not quantitatively analysed because of their small signal-to-noise ratio. Because the axis $\hat{z}$ is nearly perpendicular to our line-of-sight, only even $l + m$ components should be visible in whole-disk measurements. I therefore assume the underlying line profile (in excess of background) of each $l = 1$ peak to be a superposition of two identical lobes, representing the $m = \pm 1$ components. The observable separation of the lobes, S, is related to the sidereal splitting Δ in equation (1) by

$$S = 2(\Delta - \nu_{\rm e}) \tag{3}$$

where $\nu_{\rm e} \approx 0.03$ μHz is the orbital frequency of the Earth about the Sun. The separate lobes are assumed to have lorentzian line shapes. The $l = 0$ peaks are represented by a single such lobe. Defining the linewidth as the width of a symmetrically placed bin containing half the power in the line[2], the width of the assumed doublet profile, W_1, the width of the individual lobes,

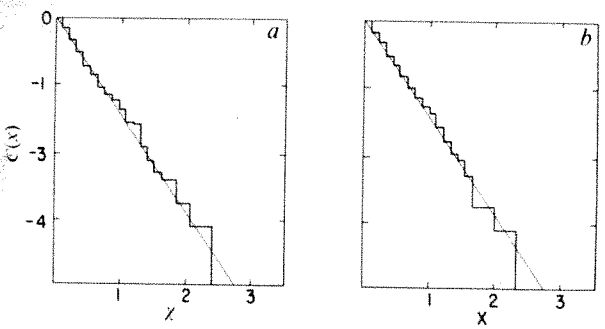

Fig. 1 *a*, The logarithm $C(x)$ of the fraction of frequency points for which the spectral power estimate p'_ν exceeds the true power by the factor x (arbitrary units), plotted for frequencies taken from 1.86-μHz bandwidth intervals centred on 5-min *p*-mode resonances in the periodogram of ACRIM data. (The true spectral power p_ν was determined from the mode parameter estimation scheme of ref. 2.) Eight intervals were selected, corresponding to the peaks $l=0$, $n=20$–23 and $l=1$, $n=19$–22. The frequency sampling of the periodogram is 29.1038 nHz so that 64 frequencies per mode were used. *b*, $C(x)$ plotted from 512 frequencies belonging to a background interval in the 5-min range. The linearity of these plots corresponds to a χ^2 distribution with 2 degrees of freedom, the distribution assumed in the error analysis. (This method of display was suggested by P. Delache.)

W_0, and the separation, S, obey a pythagorean relationship:

$$W_1^2 = W_0^2 + S^2 \quad (4)$$

The differences between the shapes of 5-min peaks in the ACRIM data and the idealized line profiles discussed above are assumed to be mainly statistical: thus linewidth measurements are subject to random error. Accordingly, I assume that the spectral power estimates p'_ν at frequencies separated by more 0.04 μHz (the resolution of 290 days of data) are uncorrelated, and that p'_ν at each frequency ν comes from a χ^2 distribution with 2 degrees of freedom, a distribution typical of a periodogram of filtered noise. The mean of the χ^2 distribution, p_ν (the true spectral power that p'_ν estimates), presumed to be a superposition of idealized 5-min mode profiles and a nearly flat background 'continuum', was estimated from the parameters of the individual 5-min modes[2] and the observed continuum.

Two tests demonstrate the credibility of these statistics. To check that the periodogram conforms to the stated distribution I have plotted $C(x)$ against x in Fig. 1, where $\exp\{C(x)\}$ is the fraction of periodogram points for which p'_ν/p_ν exceeds x. The straight line plots confirm the expected $C(x) \propto -x$ dependence, both for frequency intervals containing 5-min modes and for background intervals. To verify the statistical independence of the spectral estimate at frequencies differing by more than 0.04 μHz, I smoothed the periodogram and measured the decrease in the scatter of the points. The ratio of the variance in the smoothed periodogram to that in the original should equal 0.04 μHz divided by the effective resolution of the smoothed periodogram. This dependence was confirmed for frequency ranges of interest.

The operational definitions of power and linewidth[2] systematically underestimate the true power and width because the power in the modes is integrated only over a 5-μHz interval. A Monte Carlo simulation was performed to calibrate empirically the relation between the true power and width of the $l=0$ modes and the expected value of the operationally defined power and width, and to determine the random error of the measurement. In this, and in subsequent simulations, a statistical ensemble of artificial periodograms containing modes and background were generated with the statistical properties assumed for the real data. Ignoring the possible variation of linewidth with frequency, the true width inferred for the four strongest $l=0$ lines ($n=$ 20–23) is $\Delta\nu = 1.6 \pm 0.3$ μHz.

A second Monte Carlo calculation calibrated the relation between the width W_1 and power of the $l=1$ doublets and the operationally-defined linewidth and power, assuming that the

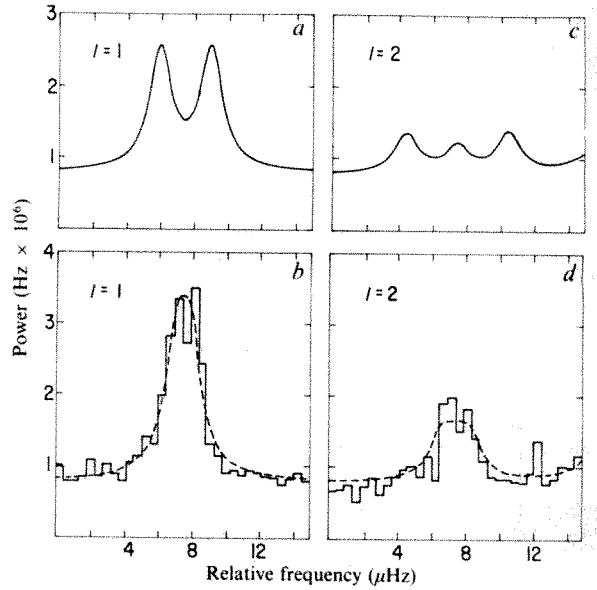

Fig. 2 *a*, Theoretical $l=1$ profile with a lobe separation of 3.0 μHz, that is a splitting $\Delta = 1.56$ μHz as defined in the text, slightly less than the separation implied by the rotation curves of refs 5 and 6. The total power in the doublet equals the mean power of the $l=1$ modes studied in this analysis and the width of the lobes equals the estimated 1.6-μHz width of the $l=0$ modes in the same frequency range. The continuum power level is that of the ACRIM data. The theoretical line shape corresponding to the larger splitting stands in marked contrast to the appearance of the actual modes. *b*, Superposition of three $l=1$ peaks ($n=20$–23) in the ACRIM periodogram, based on the measured frequency centroids, plotted at a resolution of 0.4657 μHz. The smooth curve is a doublet with a (synodic) lobe separation $S = 0.86$ μHz, the separation expected from solid-body rotation with a ~25-day sidereal period and represents the theoretical appearance of a smoothed periodogram based on an unlimited amount of data. *c*, Idealized $l=2$ profile resulting from the $\Delta = 1.56$-μHz splitting is also at variance with the data and further substantiates our conclusions. The relative power 3:2:3 in the $m=-2$, 0, and +2 lobes shown and the absence of the $m=\pm1$ lobes in full-solar-disk measurements is dictated by isotropy and by the assumption of a solar rotation axis perpendicular to our line of sight. *d*, The superposition of the four $l=2$ modes ($n=19$–22) is also consistent solid-body rotation (the smooth curve again indicates the theoretical profile which best fits the data).

doublet components have the same width as the $l=0$ modes in the same frequency range (that is, $W_0 = \Delta\nu$). This gives a mean width for the three $l=1$ modes ($n=20$–22) of $W_1 = 1.9 \pm 0.2$ μHz. A composite of the three observed $l=1$ modes appears in Fig. 2. The value of Δ inferred from W_0 and W_1 through equations (3) and (4) is 0.5 (+0.2, −0.5) μHz, consistent with the 0.456-μHz splitting expected from solid-body rotation with a ~25-day sidereal period, but also consistent with any rotational rate between 0 and 1.4 times the surface rate (1σ error limits). Note that only the magnitude of S (in equation (3)) can be determined from the (full-disk) ACRIM data. An unambiguous value for Δ was obtained by assuming that S is positive, in accordance with a net internal rotation having the same sense as the surface rotation.

Relaxing the assumption $W_0 = \Delta\nu$, made above, leads to a more rigorous upper bound on splitting. The probability of obtaining an $l=1$ linewidth smaller than the observed one, for various hypothetical values of Δ, was computed from a Monte Carlo program. In this final program, the influence of oscillations aliased into the 2,900–3,300-μHz range by the ACRIM shutter operation[2] was also simulated. Based on the published analysis of the Nice group[10], whose velocity oscillation spectrum extends well beyond the 3,814.7-μHz ACRIM Nyquist limit, the spectral power per multiplet of given l is at least three times greater at the frequencies of interest than at the frequencies of multiplets that would produce aliases. The m-state width of the potentially aliased multiplets is assumed to be 5 μHz. For each point on a

grid of mode parameters (Δ, W_0, and parameters defining the power and frequency of the aliases) a number of trial measurements were performed. A trial consists of generating three independent periodograms based on the same profile, measuring the doublet width in each, and averaging the three measurements. For $\Delta = 1.0$ and 2.0 μHz, 256 and 1,024 trials were made, respectively, for each value of the other parameters. (The ranges of the other parameters reflect their uncertainty, in particular W_0 was assumed to lie in the range 0.6–1.8 μHz.) At the lower splitting only one trial (at most) per grid point resulted in a mean width smaller than the observed one, and at the larger splitting there were no such occurrences. I thus infer a strong ($\approx 2.5\sigma$) upper limit $\Delta_{max} = 1.0$ μHz on the rotational splitting.

These results demand comparison with internal rotation curves obtained from different analyses of rotationally split modes in the solar limb-darkening data[4]. Hill *et al.*[5] have derived a rotation curve from these data which implies a solar mass quadrupole moment $J_2 = (5.5 \pm 1.3) \times 10^{-6}$, in conflict with the einsteinian general relativistic interpretation of Mercury's perihelion motion at the 2σ level. From a preliminary analysis of the same data, Gough[7] obtained $J_2 = 3.6 \times 10^{-6}$, not large enough to conflict with general relativity. Both analyses used seven multiplets for the curve fitting, a common set with the exception of two *p*-modes. A more recent analysis by Campbell *et al.*[6] essentially confirms the Hill *et al.* rotation curve, giving $J_2 = 5.0 \times 10^{-6}$, again in conflict with relativistic predictions.

To test the conclusions derived from the limb-darkening data I have calculated, using equation (2), the splitting of the low-l 5-min modes implied by the curves used to derive the quoted J_2 values. The function $c(r)$ was taken from a recent standard solar model calculation[11]. The rotation curves in refs 7, 5, and 6 imply $\Delta = 1.46$, 1.70, and 1.69 μHz, respectively, in conflict with the upper limit $\Delta_{max} = 1.0$ μHz derived here. Thus the basis established in refs 5 and 6 for conflict between general relativity and solar oscillation data is removed by the SMM data.

I thank Richard C. Willson for making the ACRIM data available, Roger Ulrich for supplying the results of solar model calculations, and A. N. McClymont for suggesting improvements in the manuscript. This research was suggested by Hugh Hudson and supported by NASA on grant NSG 7161.

A new imaging proportional counter using a Penning gas improves energy resolution

H. E. Schwarz & I. M. Mason

Mullard Space Science Laboratory, University College London, Holmbury St Mary, Dorking, Surrey RH5 6NT, UK

In recent years Siegmund *et al.*[1,2] have attempted to combine in one detector the position resolution of the multi-wire proportional counter (MWPC)[3–5] or the parallel-plate imaging proportional counter (PPIPC)[6,7] with the energy resolution of the gas-scintillation proportional counter (GSPC)[8–11], using light from avalanches in a PPIPC. By counting the light flashes from individual primary electrons, Fano factor limited energy resolution was obtained but only for energies below 2 keV. The position resolution was $\approx$350 μm over an active diameter of 25 mm. Sipilä and co-workers[12,13] used Penning gas[14,15] mixtures to improve the energy resolution to 11% at 6 keV. However, this was achieved at gas gains of <50, and in a single wire proportional counter (PC) without imaging capability. We have achieved similar resolution with gains up to 550 by using a Penning gas in a uniform field. Although satisfactory for energy measurement down to 0.1 keV this gain is not high enough for good position resolution in a PPIPC. We therefore use another stage of uniform field avalanching to boost the overall gain to values >10^5. The concept of two-stage avalanching was first reported by Charpak *et al.*[16] and used by Breskin *et al.*[17]. We have built and tested a laboratory version of such a detector (Fig. 1), which we call the Penning gas imager (PGI). A Penning gas and a two-stage parallel grid avalanche geometry are combined with a wedge and strip anode (WSA) position read-out system[18]. Preliminary experimental energy resolution is 12% FWHM at 6 keV (24% FWHM at 1.5 keV) and the position resolution is 100 μm FWHM at 1.5 keV. This compares with $\approx$10% and $\approx$1 mm for the GSPC and $\approx$18% and a few hundred micrometres for the MWPC. The particle background can be reduced by an estimated 99% using an anticoincidence technique.

The energy resolution of a PC is limited by both Fano and avalanche statistics. The FWHM resolution is given by

$$R_E(\%) = 236[w(F + f + g)/E]^{0.5}$$

where w is the mean energy to produce one ion pair, F the Fano factor, f the avalanche factor, g a broadening factor depending on the small scale grid or wire geometry, and E is the X-ray energy.

The value of F for argon (and conventional PC gas mixtures such as Ar/CH_4) is 0.17 and f is typically 0.65 (ref. 19). With $w = 26.2$ eV in argon this gives $R_E = 35E^{-1/2}$ where E is in keV. This assumes $g = 0$. In practice this resolution is not achieved due to irregularities in the anode wires[20] or the grids[7]; 18% at 6 keV is a typical value and this implies a g factor equivalent to 10% extra broadening.

In the GSPC the f and g factors are eliminated by not using avalanches. In principle, $R_E = 16E^{-1/2}$ can be achieved but a typical observed value at 6 keV is 10% compared with a theoretically possible 6%. This corresponds to an additional broadening of about 8% due to gas impurities and geometry dependent light losses in the counter.

The energy resolution of the PGI is potentially as good as that of the GSPC. By using argon with the Penning admixture C_2H_2 which has an ionization potential lower than the energy of the photons emitted by the excited Ar atoms, the admixture can be photo-ionized. Also metastable argon atoms can collisionally ionize the ethyne molecules. This process, known as the Penning effect, produces a dramatic increase in α, the first Townsend coefficient[15]. As an example, the changes in the relative efficiencies of the various processes such as excitation and ionization in a Ne/Ar mixture are shown in Fig. 2. In the initial ionization, more of the available energy of the primary photo-electron and Auger electron is used for ionization (the value of w is reduced from 26.2 to 20.3 eV)[19] and in addition the fluctuations in the energy losses are smaller. The Fano factor is thus reduced[19].

In the avalanche, using the model of Alkhazov[19] and the data on α of Kruithof and Penning, Sipilä[13] shows that for an optimum value of the field strength, f approaches zero in a (Penning) mixture of Ne and Ar. As the process for Ar/C_2H_2 is similar such a result can also be expected for this mixture. A theoretical energy resolution of $10E^{-1/2}$ is then available. Sipilä's results were obtained at low gas gains (<50) but the resolution in conventional PCs rapidly degrades with increasing gain. This is due to the strongly varying field near the anode wire which makes it impossible to use the optimum field[15,19] needed for low values of f. Sipilä was aware of this limitation and suggested the use of a uniform field avalanche[13]. In the PGI the parallel geometry provides a uniform field and much higher gains can

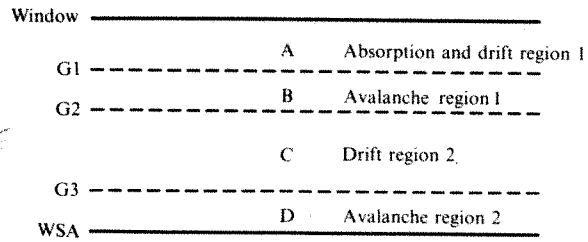

Fig. 1 Schematic diagram of the PGI. X rays enter through the thin polypropylene window and are absorbed in region A. Electrons from the resulting ionization cloud drift in a weak field through grid G1 and avalanche in the higher field of region B. The energy signal is taken from G1 and/or G2. About 20% of the avalanche electrons are effectively transferred to the second drift region C where the cloud is allowed to diffuse before reaching the second avalanche region D. The position of the electron cloud's centroid is determined using the signals from the WSA.

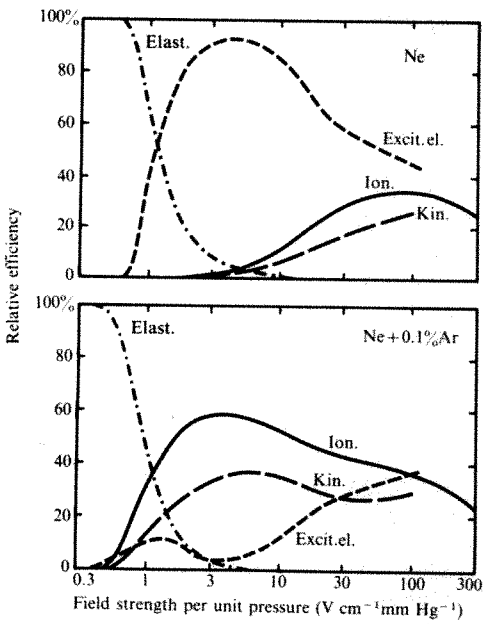

Fig. 2 Fraction of the total energy received by the electrons from the electric field which is spent in elastic collisions (Elast.), excitation of electronic levels (Excit. el.), excitation of vibrational levels (Excit. vib.), ionization (Ion.) and increase of kinetic energy of the electrons (Kin.). (From ref. 26.)

be used without the accompanying increase in R_E. With a gain of 550 we have obtained 12% FWHM at 6 keV and 24% at 1.5 keV in the laboratory detector. These measurements were made using argon with 0.5% C_2H_2. The energy resolution as a function of X-ray energy is plotted in Fig. 3. With a g factor providing a 10% broadening (we have measured 18% at 6 keV in the PGI using Ar/10% CH_4) we expect that optimizing the grid geometry would improve the energy resolution to <10% FWHM.

The gain of the first avalanche stage is set at ≈500, and ≈20% of the electrons produced here are transferred through grids G2 and G3 to the second avalanche region D. Due to the Penning effect, UV photons which pass through G2 ionize admixture molecules in region C. This process is independent of any applied field. In contrast, electron transfer in conventional counter gases can at best only take place in the ratio of the field strengths below and above the grid[21]. It has been shown[22] that with their multi-step chamber Breskin *et al.* required a Penning gas to obtain transfer at all. This is because their grids were composed of thin wires onto which the avalanches took place (not in a true parallel field) and this has the effect of reducing the transfer in a Penning gas to that of a conventional gas.

The second stage of amplification is used to boost the overall gain to $>10^5$. This is necessary for the WSA position read-out

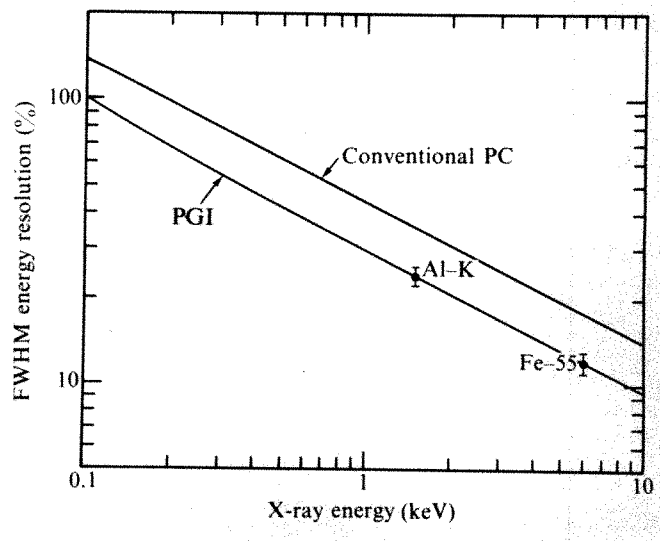

Fig. 3 The energy resolution of the PGI as a function of X-ray energy. Indicated are the resolution curves for a conventional proportional counter (PC) and for the PGI. The slight upturn in the PGI curve is due to the electronic noise contribution.

system which consists of three conductive electrodes deposited onto an insulating substrate. Their geometry is such that a linear, two-dimensional positional variation in charge output is obtained, allowing the position of an event to be determined by a simple algorithm. Preamplifier noise is associated with this charge measurement. In addition the division of charge among the discrete electrodes is binomially distributed and this gives rise to a contribution to the position resolution called partition noise.

In the same laboratory detector (70 mm diameter) we obtain a position resolution of 100 μm FWHM at 1.5 keV with a gain of 1.3×10^5. We have also built a PGI with a 200 mm diameter WSA whose overall noise is such that for all but the lowest energies (<0.5 keV) the resolution is dominated by electron diffusion in the absorption region (A) while at the higher energies the effect of primary electron track length[23] is dominant. This represents >1,000 FWHM resolution elements over most of the energy range.

In space, the background count rate due to charged particles is a problem for X-ray astronomy. This background is most effectively reduced[24,25] by surrounding the X-ray detection volume except for the entrance window by anticoincidence guard detectors. In the case of the PGI we are able to surround the WSA by an annular anode and use it with the second drift/avalanche region to provide such a detection volume. By comparison with previously flown detectors using this type of background rejection scheme, we expect to be able to reject >99% of the particle events in space[24,25].

Finally, several further improvements to the PGI are under consideration. First, the use of a xenon based Penning mixture as the filling gas will increase the quantum efficiency (QE) of the detector at high energies (in argon the QE is typically 70% at 1.5 keV and 35% at 6 keV). Second, a fast high-voltage switching circuit can be used to make the number of electrons reaching the WSA independent of the X-ray energy. This feedback system reduces the dynamic range needed for position signal processing by a factor of about 80. Third, cooling of the first stage preamplifier would improve the energy resolution at low X-ray energies by reducing the contribution due to electronic noise.

We are designing a flight version of the PGI which, with an imaging X-ray telescope will form the payload of an Aries sounding rocket to be launched in 1985.

We acknowledge the encouragement and support of Professor J. L. Culhane and thank the people of the MSSL engineering design office and the mechanical workshop for the detailed design and manufacture of the prototype detectors. This work was supported by SERC.

Effect of a heated patch of auroral ionosphere on VLF-radio wave propagation

R. Barr*, M. T. Rietveld†, H. Kopka†& P. Stubbe†

* Geophysical Observatory, PO Box 2111, Christchurch, New Zealand
† Max-Planck-Institut für Aeronomie, 3411 Katlenburg-Lindau 3, FRG

In the early 1960s, during the period of atmospheric nuclear tests, much theoretical interest developed in the effects of localized ionospheric depressions on the propagation of very low frequency (VLF) radio waves[1–4]. Similar VLF-propagation effects are also produced by the localized dumping of electrons from the radiation belts after wave–particle interactions[5,6]. Both nuclear explosions and particle precipitation events are of a transient nature, however, and no experimental study has yet been made to confirm these early theoretical predictions. With the development of a unique high frequency (HF) heating facility near Tromsø, Norway, the generation of movable controlled anomalies in the *D*-region has become possible. We describe here some initial observations, made in Norway, of the effect of such a movable *D*-region anomaly on the VLF signals received from the 12.1-kHz Omega transmitter at Aldra. The observations confirm the validity of earlier theoretical predictions.

Figure 1 shows the region of northern Scandinavia pertinent to the experiment. The VLF receiver used for the measurements was located at the Skibotn Astronomical Observatory, 443 km north-east of the Omega VLF transmitter at Aldra. The HF heating facility was located at Ramfjord, 15 km south of Tromsø.

The heater antenna array consisted of six rows of six crossed full-wave dipoles[7]. By suitably adjusting the relative phases of the drives to the different rows of the heating antennas, it was possible to deflect the heating beam ±56° from the vertical in the north–south plane[8]. Assuming a height of 80 km for the region of maximum *D*-region heating[9], the volume of maximum heating effect, defined by the −3 dB points, could thus be displaced 120 km north or south of Ramfjord. However, while the heated region was circular with ~20-km diameter when the beam was vertical, the heated volume had an elliptical cross-section with major axis of ~70 km and minor axis of ~38 km (see Fig. 1) when the beam was displaced 56° south or north. The experiment reported here simply entailed observing the phase and amplitude of the normal magnetic component of the

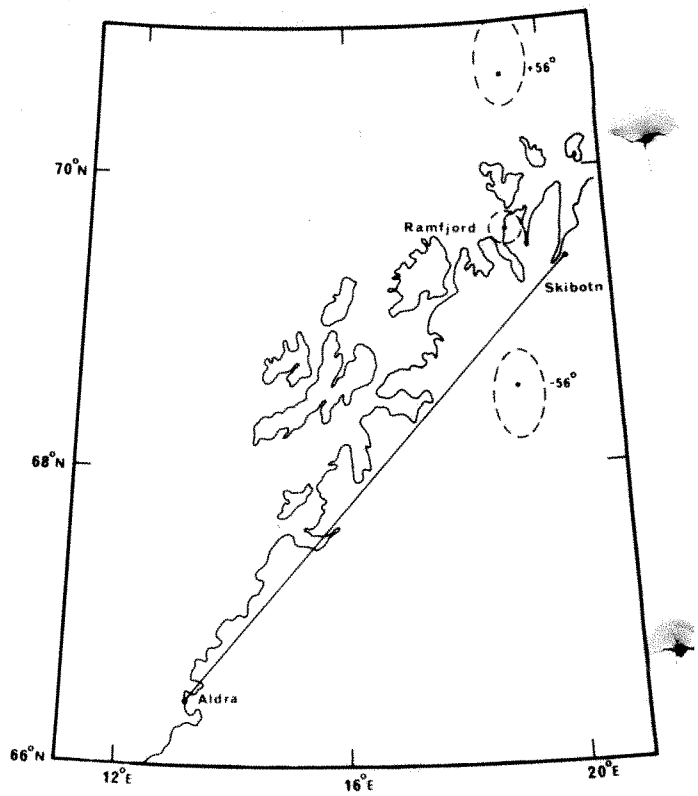

Fig. 1 Map of northern Scandinavia showing the location of the Omega station at Aldra, the VLF receiving station at Skibotn and the heating facility at Ramfjord. The dashed circle and dashed ellipses are approximate representations of the antenna −3 dB (half power) points at 80 km. The circle applies to a vertical beam, the ellipses to a beam deflection of 56° from the vertical to the north or south of the transmitter.

12.1-kHz signals from the transmitter as the heater beam was deflected across the Skibotn/Aldra propagation path. Due to the fixed locations of the heating facility and VLF transmitter, it was not possible to locate a land-based VLF receiver at a sufficiently high latitude that the heater modified the midpoint of the VLF propagation path. The optimum configuration adopted by Jones *et al.*[10] was thus not possible. It was therefore decided to locate the receiver at the most convenient experimental location, this being the Skibotn Astronomical Observatory. With this geometry it was decided that the total normal magnetic component of the VLF signal should be recorded with the eventual aim of analysing the data using a full waveguide analysis based on the work of Crombie[4] and Wait[3], the simpler analysis in terms of reflection coefficients not being feasible with such an asymmetric geometry.

Calculations[9] show that for an effective radiated power (ERP) of 300 MW at 2.759 MHz in the x-mode, the collisional frequency in the *D*-region increases by at least a factor of 5 over a height range of ~10 km. Assuming that this modification can be modelled as a 10-km elevation of the ionosphere over an area of 30 km diameter: this increased collisional frequency results in an increase of the effective VLF reflection height by 10 km, then according to the work of Field and Engel[11] a wave passing through the midpoint of such an elevated region would suffer a phase change ~ −0.4°. Experimental verification of such a small effect on VLF propagation thus entails measurement of VLF phases angles with a resolution of better than 1/10°.

Resolution is not the only significant parameter in the experiment, however, the phase stability during the experiment is also important. Experience suggests that long-term stability of VLF propagation in the auroral zone is not high[12,13] and thus the technique described below was used to offset the effect of ionospheric variability on a time scale of >2 s.

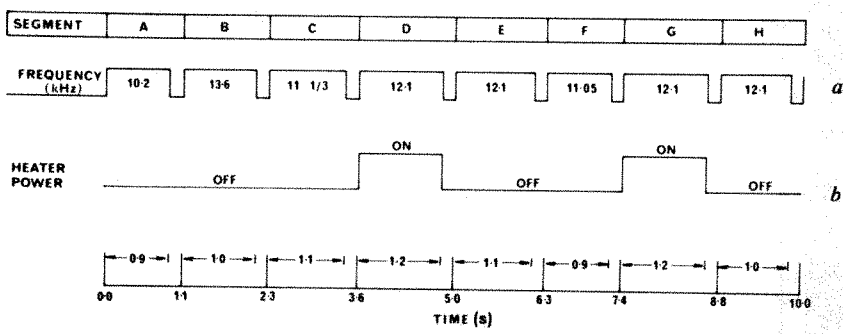

Fig. 2 *a*, Norwegian Omega transmitter format. *b*, Heating transmitter switching format. Cycles repeat every 10 s.

Figure 2*a* shows the Omega transmission format, together with the four periods of 12.1-kHz transmission. Figure 2*b* shows the period during which the heater was in operation (2.759 MHz, ERP = 200 MW). As can be seen, the heater was on for the first and third 12.1-kHz segments. By subtracting phase measurements recorded between the first and second or third and fourth 12.1-kHz segments the effect of heating could be determined over a 2-s interval, thus reducing the effect of longer-term phase variations. By operating the heater with this pulse format for 1 min, at each setting of a beam deflection angle, it was thus possible to get a mean of 12 phase difference readings at each position of the beam.

Figure 3 shows the phase and amplitude anomalies on the normal magnetic component of the Omega 12.1-kHz signal at Skibotn, recorded using the above technique. The readings were obtained from 13.45 to 14.24 UT on 29 September 1983 whilst the beam was deflected from 16 °N of Ramfjord to 56 °S. Although the maximum phase anomaly is quite small, typically ±0.5°, there is obviously a clear oscillatory variation of phase with position of the beam as predicted by the earlier theoretical works[2–4]. The maximum oscillations in amplitude are also very small, only 0.1 dB, and yet they also clearly show the same oscillatory behaviour with maximum phase displacements occurring at the same deflection angle as minimum amplitude displacements and vice versa. This 90° phase shift in amplitude and phase oscillations is in excellent agreement with the work of Wait[3] displayed in Fig. 4. The dashed and solid curves show the amplitude and phase oscillations computed for an anomaly 100 km square as it moves along the perpendicular bisector of a 10^7-m propagation path. The coincidences of maxima in phase deflection with minima in amplitude are clearly evident. (The amplitude and phase anomaly scales are normalized to those produced by a similar depression extending the full width of the path.) The experimental results can be seen to be in excellent qualitative agreement with the theory. The quantitative agreement between theory and experiment will now be considered.

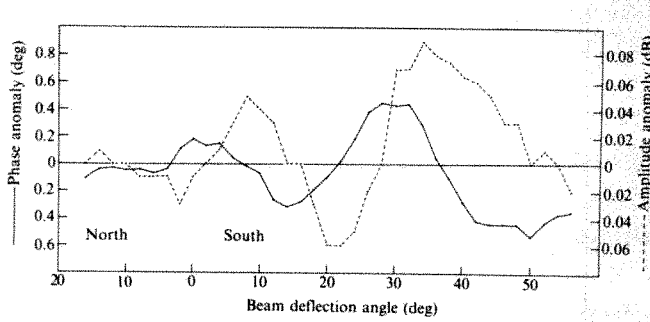

Fig. 3 Experimentally-determined values of phase and amplitude anomalies. The anomalies are plotted as a function of angular deflection of the heating beam from the vertical.

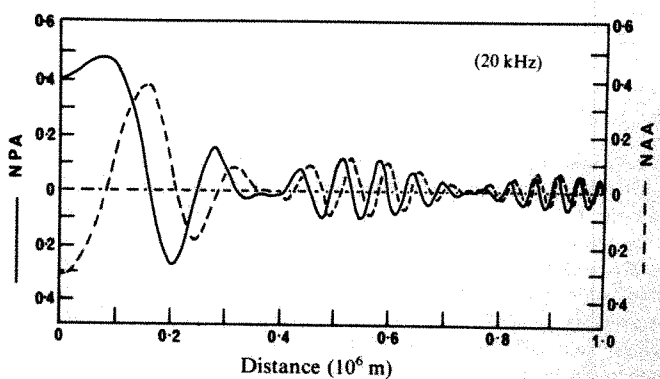

Fig. 4 Theoretical estimates of the normalized phase anomaly (NPA) and normalized amplitude anomaly (NAA) produced by an ionospheric depression 100 km square. The normalized values are plotted as a function of distance of the depression along the perpendicular bisector of the transmitter–receiver propagation path, measured from the midpoint of the path (after ref. 3).

If the effect of the heater can be modelled as a 10-km elevation of the ionosphere over a circular area of 30 km diameter, then the theory of Field and Engel[11] and Wait[1] predicts a phase anomaly of −0.4° for a ray passing through the middle of the elevated region. The heated patch in this experiment is approximately centred on the VLF propagation path for a beam deflection angle of 40 °S (see Fig. 1). At this position the patch is elliptical with major and minor axes of ~36 and ~28 km respectively. The phase perturbation of −0.42° observed at this angle (see Fig. 3) is thus in excellent agreement with theoretical predictions.

The early theoretical work of Crombie[4] and Wait[1–3] thus seems adequate to explain the phase and amplitude anomalies caused by ionospheric elevations and depressions both on and adjacent to VLF propagation paths.

The magnitude of the phase and amplitude disturbances observed here are of a similar order although somewhat smaller than those observed by Jones *et al.*[10] using the 50-MW heating transmitter at Platteville. However, they observed the phase and amplitude anomalies on the 'abnormal' magnetic component received on a 128-km propagation path when only the midpoint of the path was heated by a fixed HF beam. The total normal magnetic field was recorded in this study, which inevitably included a large component of unmodified ground-wave and this may account, to some extent, for the smaller effects observed in this experiment.

Note that the work of Wait[1–3] and Crombie[4] applies only to single-mode propagation, whereas on the short paths used in this experiment a number of modes probably contribute to the received signal even under daylight ionospheres. In nighttime conditions multimode propagation will almost certainly be significant and enhanced anomalies due to heating may be expected[6]. Similar enhancements, but invoking multipath propagation within the ionosphere, have been used to explain large amplitude anomalies on steep incidence LF data[14]. Since this initial study, further experimental observations have now been made in both daytime and nighttime conditions, and enhanced effects due to modal interference have been observed. These results will soon be submitted for publication, together with a full wave analysis of the diffraction effects produced by a heated patch of ionosphere in multimode propagation conditions.

We thank Erik Solheim from the Auroral Observatory, Tromsø for allowing them to use the facilities of the Skibotn Astronomical Observatory and the Deutsche Forschungsgemeinschaft (DFG) for its support of the heating project. R.B. thanks the

Delayed phase change due to hot asthenosphere causes Transantarctic uplift?

A. G. Smith

Department of Earth Sciences, University of Cambridge, Downing Street, Cambridge CB2 3EQ, UK

D. J. Drewry

Scott Polar Research Institute, University of Cambridge, Lensfield Road, Cambridge CB2 1ER, UK

The Transantarctic Mountains are one of the world's major mountain chains, extending 3,500 km across Antarctica in a belt 200–500 km wide (Fig. 1). The region has been uplifted by at least 4 km since late Mesozoic time, yet there is none of the thrusting, folding, regional metamorphism and andesitic volcanism associated with many other large Cenozoic mountain ranges and apparently related to subduction and subsequent continental collision. Instead, the uplift of the Transantarctic Mountains is attributed here to the delayed effects of the overriding by east Antarctica of anomalously hot asthenosphere forming under west Antarctica in the late Cretaceous. Temperature increases of 100 °C are estimated at the base of the lithosphere, with mantle heat flux increasing by ~3.5 mW m^{-2}. These changes cause an inferred uplift rate of 90 m Myr^{-1} some 50 Myr later. The late Cenozoic volcanism in the Transantarctic Mountains, typified by activity in Victoria Land, is attributed to the previously heated continental lithosphere overriding hot asthenosphere that was brought under Antarctica when it separated from Australia.

The continental uplift model used here proposes that rapid uplift will lag some 50 Myr behind the overriding of anomalously hot asthenosphere by a continent. An estimated mantle heat flux increase of 3.5 mW m^{-2} is believed to cause phase changes in the uppermost continental mantle[1]. In the absence of palaeoflow models for the asthenosphere, empirical reference frames must be used to locate hot asthenosphere and relate it to plate motions.

For interpreting the later Cenozoic uplift of southern Africa, a reference frame fixed to South America seems to be useful[1]. It has been suggested that anomalously hot asthenosphere in this frame was located at the positions of former oceanic ridges. It has also been assumed that when continental lithosphere moves over former ridge positions in this frame the hot oceanic asthenosphere is overridden by the continent rather than being carried with the oceanic lithosphere. Such a continental area would experience uplift and a higher mantle heat flux which would affect the postulated phase changes near the Moho some 50 Myr later. Later Cenozoic uplift of south-east Australia appeared to be accounted for by this model. The 'hotspots' reference frame apparently did not account for the uplifted regions of southern Africa. This frame is probably as good as the South American frame for discussing the uplift of south-east Australia, although a comparison was not made in the original work. In the case of the Antarctic, the hotspots frame of Morgan[2] gives similar results, largely because South America has not moved much relative to the hotspots frame in south polar latitudes.

Why these particular frames are useful is not well understood. They may reflect the fact that zones of upwelling asthenosphere move slowly in a fixed lithospheric angular momentum reference frame[3–5] and that South America approximates to such a frame today[6]. Their usefulness supports the assumption that hot oceanic asthenosphere can be overriden by continental plates.

Late Cretaceous to early Tertiary extensional zones have been postulated in Antarctica[7–11] to account for the development of the continental mosaic that now makes up west Antarctica. The isostatically adjusted bedrock surface of west Antarctica lies mostly at ~500 m below sea level, in marked contrast to the 1,000 m or more average elevation of east Antarctica[12]. The presence of significant volumes of volcanic rocks at depths as great as 2 km below sea level in the Byrd sub-glacial basin, suggested by seismic[13] and magnetic studies[10,11], may relate to a period of incipient ocean floor formation.

Whether or not any ocean floor was created, west Antarctica seems to have been stretched[14]. Such stretching would have brought hot asthenosphere nearer the surface. The age of the extensional zone, running along the edge of the Transantarctic Mountains is not known. It is probably no older than the separation of the Pacific plate from the Antarctic plate, whose age can be inferred to be about 91 Myr by extrapolating to closure the positions of the two plates at anomalies 29 and 32 yr (ref. 15). It is older than the anomalies now lying against the Antarctic continental edge, probably about 65-Myr old[16].

Figure 1*a*, *b* show the maximum size of the area in the hot-spots and South American reference frames previously occupied by west Antarctica that could have been overridden

Table 1 Uplift rates in the Transantarctic Mountains

Age	Locality	Observation and inference
Late Pliocene (2.5–3.4 Myr)	Wright Valley, South Victoria Land (77.5°S, 162°E)	Benthic foraminifera, originally at 10–100 m below sea level, now at 160 m (ref. 24) Uplift rate = 50–105 m Myr^{-1}
Late Miocene–early Pliocene,	Taylor Valley, South Victoria Land (77.7°S, 163°E)	Benthic foraminifera, originally 600 m now at 120 m below sea level[25]. Uplift rate in past 5 Myr of 80–100 Myr^{-1}
Miocene (15 Myr)	Miller Range, Nimrod Glacier (83.3°S, 157°E)	Glacial erosion cut at 1–1.5 km now at 2.5 km (ref. 26) Uplift rate = 80–100 m Myr^{-1}
15.7–18.3 Myr	Queen Maud Mountains (87°S, 154°E)	900 m of pre-volcanic relief; hence minimum height of region now at 2.5 km (ref. 27) Maximum uplift rate = 90 m Myr^{-1}
Post–late Cretaceous	Queen Maud Mountains (86.5°S, 150°E)	'Several thousand metres' vertical movement[28]
>25 Myr	Transantarctic Mountains	Elevation 500–1,500 m for first highland glaciers at 25 Myr (ref. 29) Uplift rate = 40–80 m Myr^{-1}

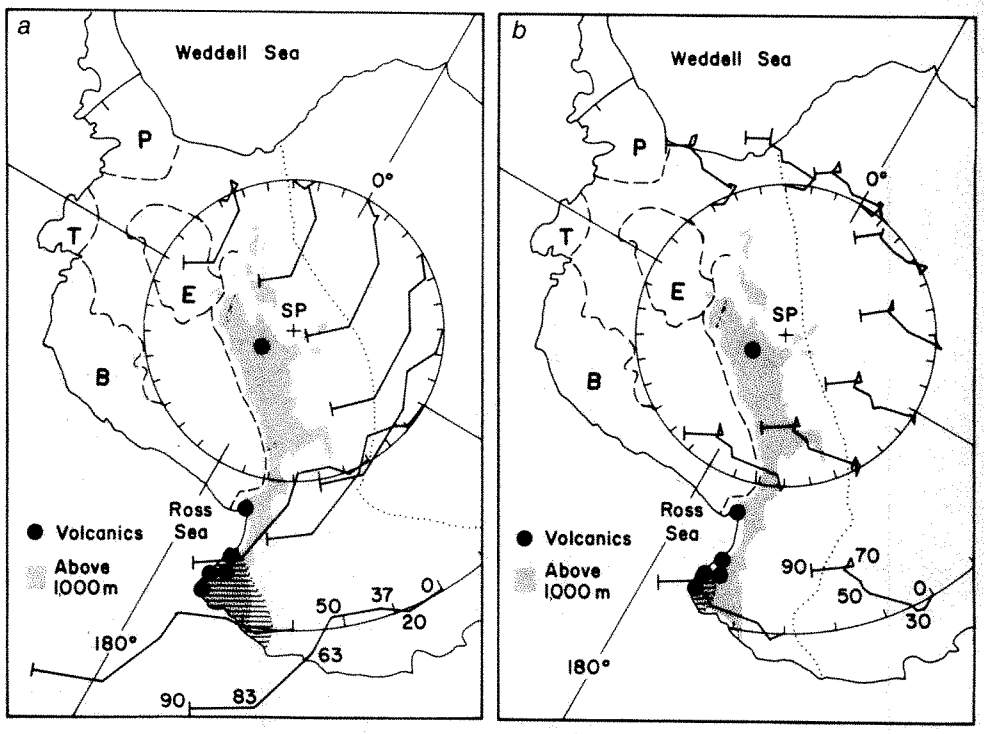

Fig. 1 The approximate outline of the Antarctic coast or coastal ice; a present-day geographical grid with latitude circles at 10° and longitudes at 10°; areas of the Transantarctic Mountains higher than 1,000 m after upward correction for the present-day ice load[12] in stipple; principal late Cenozoic volcanic fields in the Transantarctic Mountains as circles; and possible boundaries between major continental fragments as dashed lines. *a*, Solid lines show the successive past positions of points on the present-day geographical grid in a reference frame fixed to South America. Only one track has been labelled, the numbers are ages in Myr back to 90 Myr. *b*, As *a* but the tracks are taken from the hotspots frame of Morgan[2]. The dotted line in *a* and *b* shows the present position of a line that originally lay along the boundary between east Antarctica and the western edge of the Transantarctic Mountains in each reference frame. In both cases the high topography of the Transantarctic Mountains is parallel to this boundary but well within it. The horizontally shaded area in *a* and *b* is the area in each reference frame that could have overridden a former ridge position formed in early Cenozoic time.

by east Antarctica and hence subject to later uplift in the past 90 Myr. According to the model, these areas were underlain by anomalously hot asthenosphere. The uplifted area should be smaller—because of the time lag between overriding and uplift; it should form an asymmetrical mountain range decreasing in height towards the interior of east Antarctica; and significant uplift may have started within the Cenozoic, depending on the age of the extensional zone and the time-lag between overriding and uplift. The most likely age is thus about 40 Myr. As shown below, the heat needed for the phase change is small and causes negligible thermal expansion. Thus the uplift of the Transantarctic Mountains should start at a slow rate as soon as overriding begins, but will rapidly increase once the heat reaches the phase change.

Figure 1*a*, *b* show the high topography of the Transantarctic Mountains allowing for isostatic uplift following removal of the present-day ice load[12]. Several independent lines of evidence, summarized in Table 1, allow an uplift curve to be constructed for these mountains (Fig. 3).

Rates of uplift inferred from glaciological and palaeontological evidence (Table 1) are in reasonable agreement with 'erosion rates' deduced independently from fission track results on apatites in dated granite plutons from south Victoria Land[17]. They indicate slow uplift (or 'erosion rate') of 15 m Myr^{-1} for the period ~157–45 Myr. A pronounced break was detected at 45 Myr with a subsequent rate of ~93 Myr^{-1} (taking an elevation of the 100 °C isotherm at 3.8 km below sea level, based on an average geothermal gradient of 30 °C km^{-1} (refs 18–20)).

Some areas of plateau uplift are also associated with volcanism, but its timing and distribution are variable and therefore less easy to predict. In southern Africa there is no significant volcanism associated with Cenozoic uplift. By contrast, southeast Australia shows two distinct episodes of basaltic volcanism. The younger phase shows a southward migration attributed to the overriding of the hot asthenosphere originally under the Coral Sea[1]. The time-lag between overriding and the peak of the volcanism here is ~10 Myr.

The model suggests that if volcanism takes place it will be predominantly basaltic, although volcanism is not an *a priori* requirement of the model. The most probable position for volcanism is within the Transantarctic Mountains, with an age of perhaps 45–70 Myr. Later volcanism might also occur in north Victoria Land, where the previously heated lithosphere of east Antarctica has overridden hot asthenosphere brought to the base of the lithosphere by Cenozoic ocean-floor spreading at the edge of the Antarctic continent. This volcanism would have started about 20 Myr ago and should be increasing in intensity, reaching its maximum development today. The predicted extent of the area affected is shown on Fig. 1*a*, *b*.

Basaltic volcanism in Antarctica is concentrated in several provinces, although no attempt is made here to investigate it outside the Transantarctic Mountains. Here basaltic volcanism is sited principally in Victoria Land, with a minor centre in the Queen Maud Mountains (Fig. 1*a*, *b*)[21].

There is reasonable agreement between the predicted and observed timing, form and distribution of the uplift of the Transantarctic Mountains. The uplift of the Transantarctic Mountains may well have been an important factor in establishing a continental ice sheet on the Antarctic. Because stages in

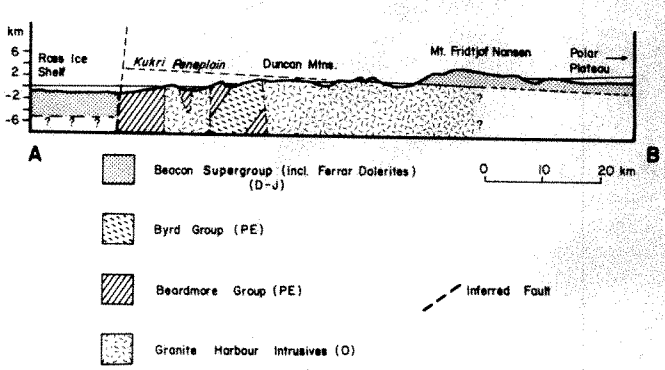

Fig. 2 Schematic cross-section through the Transantarctic Mountains at Mt Nansen (85°S, 165°W). The Kukri Peneplain separates the Beacon Supergroup (including the Ferrar dolerites) from the deformed or intrusive basement rocks. The Beacon section dips gently inland at a few degrees, from ref. 30.

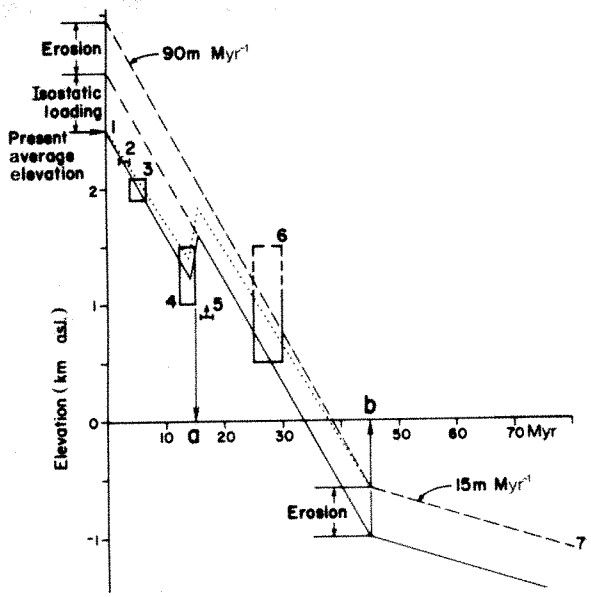

Fig. 3 Crude uplift curve for the Transantarctic Mountains. The curve has been constructed from data sources which are given in Table 1. The curve starts at the present-day average elevation of the mountains, determined as 2.5 km from a detailed analysis of USGS topographic maps (scale 1:0.25 M). The effects of the development of the east Antarctic ice sheet at about 15 Myr, assuming ice build-up over a period of 200 kyr, would have been to load the crust and depress it by an average amount of 0.5 km^2. This generates a discontinuity in the uplift curve. Before 15 Myr and back to 45 Myr the estimates, particularly from fission track studies[18], indicate a mean uplift rate also of the order of 90 m Myr^{-1}. The fission track results show a pronounced break at 45 Myr preceded by rate of 15 m Myr^{-1}. Superimposed on the uplift curve are the unknown effects of erosion. Lacking any quantitative determinations of erosion rate in the Transantarctic Mountains a global average value of 10 m Myr^{-1} has been used, but this is probably a minimum for mountainous terrain. This yields almost 500 m of surface lowering since the beginning of rapid uplift. The arrowed points locate, on the time axis, the approximate inception of a full continental ice sheet in Antarctica (a) and the commencement of the period of rapid uplift (b). Data sources: 1, present average elevation of the mountains; 2, from ref. 24; 3, from ref. 25; 4, from ref. 26; 5, from ref. 27; 6, from ref. 29; 7, from ref. 18.

ice-sheet growth can be dated and related to topography, Antarctica at present gives much more detailed information about its uplift curve than do southern Africa or south-east Australia. Unfortunately, the reverse is true of the history of the inferred extensional zone in Antarctica. Nevertheless, the changes in heat flow and temperature required for the model can be estimated.

A steady-state uplift rate of 90 m Myr^{-1} (Fig. 3) and a postulated enthalpy for the phase change of 46 kJ kg^{-1} implies a steady-state heat flux of about 3.5 mW m^{-2} (ref. 1). This is about 6% of the average heat flux. Adopting reasonable values for the thermal properties of the lithosphere, a heat flow increment of this magnitude would cause thermal expansion at a rate of ~m Myr^{-1}, which is negligible. Because most of it must go into driving the phase change, the increased heat flux will be virtually impossible to detect from surface measurements. For either the 'basalt-eclogite' or 'granulite-quartz eclogite' phase changes, 4 km of uplift implies that ~30 km of eclogite or quartz eclogite have inverted to the low density form. If the lower continental crust is of intermediate composition, then the granulite–quartz eclogite transformation is more likely[22]. The inferred 3.5-mW m^2 heat flux represents some 10–17% of the inferred mantle heat flux in continental regions[23]. With a mantle conductivity of 3.4 W m^{-1} $°C^{-1}$ (ref. 23), this would cause a temperature increase of about 1 °C km^{-1}, giving a temperature increase of about 110 °C at the base of the lithosphere.

There appears to be no early Cenozoic volcanism associated with the initial overriding of east Antarctica onto the postulated linear heat source. The nature, timing and approximate position of the late Cenozoic volcanism is reasonably well explained by the model.

Uplifted areas associated with basaltic volcanism like those of south-east Australia and east Antarctica might also enable different reference frames for inferring gross flow patterns in the asthenosphere to be distinguished. In the case of the uplift and volcanism of Antarctica, there is no clear distinction between a frame fixed to South America or the hotspots frame.

A.G.S. thanks NERC research grant GR3/4405 that enabled the maps to be drawn, and C. Hartnady for suggesting that the delayed phase change model might be applicable to Antarctica. We thank M. J. Bickle, D. Elliot, J. F. Harper, J. W. Morgan, F. L. Sutherland and R. I. Walcott for helpful comments and B. Parsons and J. Sclater for permission to use their digitized ocean-floor anomalies. D.J.D. thanks NERC for research grant (GR3/2291) under which certain data used in this work were collected. Adele Prowse drafted the diagrams. Cambridge Earth Sciences contribution no. 505.

Possible gyre–gyre interaction in the Pacific Ocean

Klaus Wyrtki & Jan Wenzel

Department of Oceanography, Hawaii Institute of Geophysics, University of Hawaii, Honolulu, Hawaii 96822, USA

The subtropical anticyclonic gyres of the North and South Pacific Ocean are among the largest circulation systems found in the ocean. The gyres contain the warm waters of the warm water sphere[1,2], and the rotation of these water masses is subject to low-frequency variations[3]. The presence in these gyres of baroclinic Rossby waves with periods of many years has been documented[4,5] and this seems to be sufficient proof that the gyres undergo vacillations. Using sea-level data we demonstrate here that the subtropical gyres of the North and South Pacific oscillate with a period of about 4 years and that these oscillations are probably induced by the major El Niño events.

Oscillations of the subtropical gyre in the North Pacific Ocean have been established[3], but in the Southern Hemisphere there are insufficient hydrographic data to show that the thermal or density structure of the gyre, or its water volume, undergoes systematic low-frequency variations. There is some evidence in sea-level data of an annual oscillation between the two hemispheres, but this seems to be largely a thermal signal restricted to the surface layer[6]. Sea level along the coasts of South Australia and California shows low-frequency correspondence, which has been linked with heat and water exchange between the Pacific and the Indian Oceans through the Indonesian Waters[7].

During 1974–75 a network of sea-level gauges was established on islands in the Pacific to monitor sea-level variations[8]. Monthly mean values of sea level during the period 1975–81 were analysed by using empirical orthogonal functions[9]. The first of these functions, accounting for 42% of the non-seasonal variance, reflects an east–west oscillation of the equatorial Pacific, and its time-dependence is related to the 1976 El Niño event. Its spatial distribution closely resembles the model calculations of McCreary[10]. The second function, accounting for 11% of the variance, constitutes a north–south oscillation across the Equator. It has maximum opposite amplitudes around the Hawaiian Islands in the North Pacific and in the vicinity of Samoa and the Solomon Islands in the South Pacific. The oscillation goes through slightly more than one full cycle during the 7-yr period covered by the data, and its identification led to analysis of longer time series.

To investigate the oscillation further, the longer sea-level records at Honolulu (21° N 158° W, 1905–82) and Pago Pago (14° S 171° W, 1949–82) were subjected to a spectral analysis for the common period of data (Fig. 1). Spectral energy is high at low frequencies with periods between 3 and 4 yr. Highest coherence (0.74) between Honolulu and Pago Pago in the low-frequency range is found at a period of about 4 yr and is significant at the 87% confidence level. The oscillation at the two stations is almost completely out of phase—Pago Pago leads Honolulu by 160°. This analysis indicates that the two gyres fluctuate out of phase with typical periods around 4 yr, which is also evident from the original records and their difference (Fig. 2). Typical amplitudes of these fluctuations are 5–8 cm at each station.

We interpret the observed sea-level fluctuations as oscillations among the two large subtropical gyres of the Pacific. Each gyre constitutes a mass of warm water, which is deepest in the subtropics and near the western side of the ocean. This water mass rotates in an anticyclonic direction. If the rate of rotation or angular momentum of the gyre changes, the associated density structure must adjust because of the geostrophic balance. The

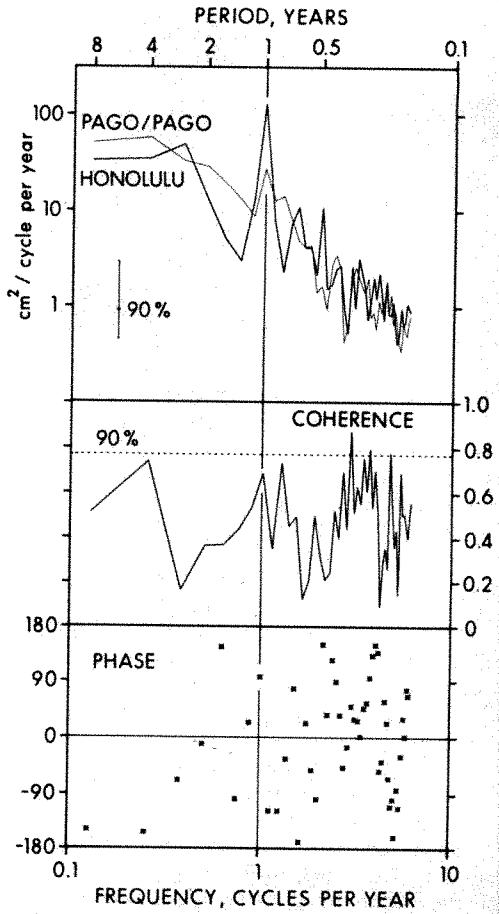

Fig. 1 Spectra of monthly sea level at Honolulu and Pago Pago for the period 1951–82, their coherence and phase for frequencies between 10 and 0.1 cycles yr^{-1}.

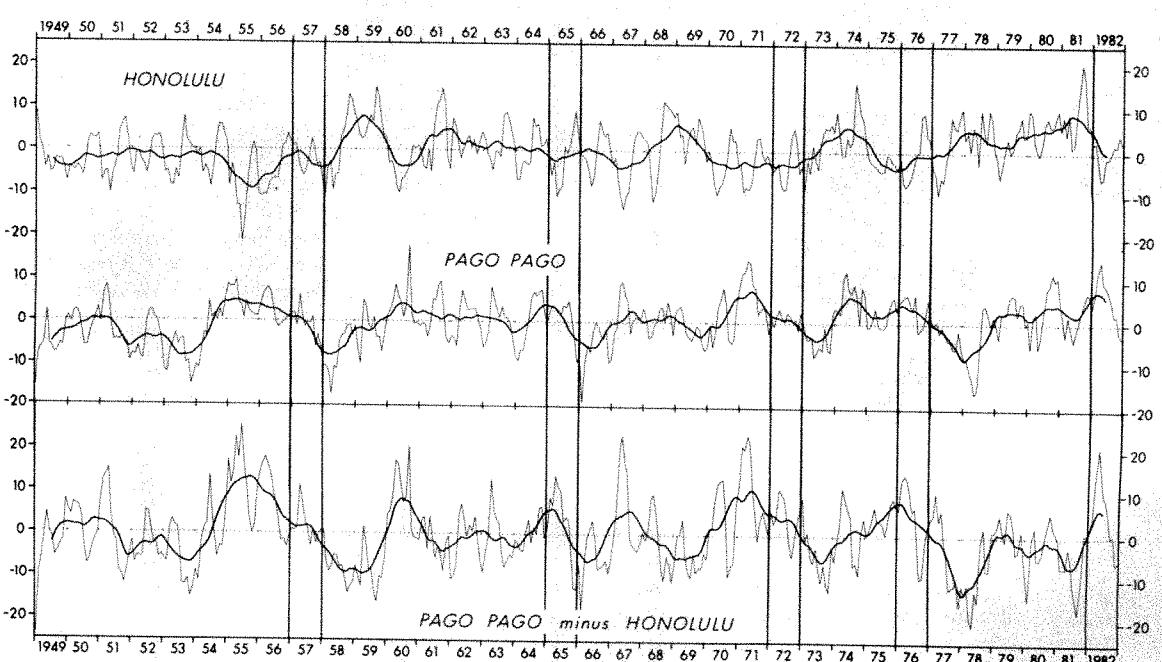

Fig. 2 Monthly mean sea level at Honolulu and Pago Pago and their difference (in cm) from 1949 to 1982. The thick curves give the 12-month running means. The major El Niño events of 1957, 1965, 1972, 1976 and 1982 are indicated by vertical lines.

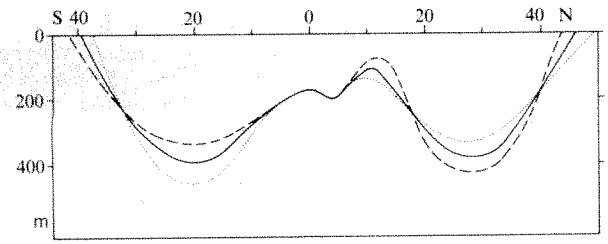

Fig. 3 The shape of the thermocline across the two subtropical gyres (solid line) and possible modes of fluctuations (dashed and dotted lines).

nature of this adjustment is sketched in Fig. 3; an acceleration of the circulation would depress the thermocline in the centre and raise it along the periphery of the gyre. A deeper thermocline implies a higher sea level because of the hydrostatic relation. If the relative density contrast between the upper layer of the gyre and the deep ocean $\Delta\rho/\rho$ is 3×10^{-3}, the depth of isopycnals in the thermocline would change 20 m for a sea-level change of 6 cm. With a depth of the gyre of 500 m, the change in the geostrophic transport of the gyre corresponding to a sea-level change of 6 cm would be $\sim4\times10^{6}\,m^3\,s^{-1}$ or about 10% of the gyre transport. Hydrographic data are inadequate to detect such small low-frequency changes in the depth of isopycnals, but transport fluctuations of similar magnitude in the North Pacific gyre have been documented[3].

Three basically different possibilities exist for the adjustment. (1) If the mass of water in each gyre remains constant, the two gyres might vacillate independently and with different periods. (2) If water is exchanged between the two gyres, this exchange has to occur across the Equator and the two gyres would be necessarily coupled. In this case the gyres have to oscillate out of phase, as is observed. (3) It is also possible that the two gyres are dynamically coupled and oscillate without exchanging mass.

It is difficult to speculate about the forcing of the oscillation. It is possible that wind torque over one of the gyres accelerates its circulation. If the two gyres were dynamically coupled, this could lead to the acceleration of the other gyre, but the oscillation would be appreciable only if a natural resonance frequency existed. This possibility could be investigated by a hydrodynamical model and the computation of the free oscillations of such a two-gyre system. On the other hand, a trans-equatorial water transport could force a coupling between the two gyres, but this coupling would not necessarily cause an acceleration or deceleration of the gyres.

The oscillations of sea level at Pago Pago (Fig. 2) follow a definite pattern related to major El Niño events. On each occasion sea level is high before El Niño, sea level drops during El Niño and is low near the end of and immediately after El Niño. In contrast, sea level at Honolulu does not show such a clear relation to El Niño events, but sea level at Honolulu peaks between such events, namely in 1959, 1968, 1974 and 1981. The difference of sea level between Pago Pago and Honolulu reflects the oscillation even better and shows its relation to major El Niño events. During each El Niño the sea-level difference is high before the event, drops during the event and is low after the event. This is the case for the major El Niño events of 1957, 1965, 1972 and 1976. Similar weaker fluctuations occur around 1960 and 1967, at a time when no El Niño occurred, indicating that the 4-yr oscillation among the two gyres is a phenomenon separate from El Niño, but might be triggered by it.

It seems possible that the north–south oscillation between the two subtropical gyres is triggered by the massive redistribution of warm water during major El Niño events. Sea-level observations of the 1982–83 El Niño show that warm water drained from the western Pacific north of the Equator during the second half of 1982 and caused a first peak of sea level in December 1982 at the Galapagos Islands. During the first half of 1983 warm water drained from the area between the Solomon Islands and Tahiti, causing a second peak in sea level at the Galapagos Islands in May 1983. During the early part of 1983 the subtropical anticyclonic gyre of the South Pacific was apparently displaced south by 10° latitude[11]. It is likely that major El Niño events trigger the oscillation among the two subtropical gyres, which continues in the years after the triggering until a subsequent El Niño event starts the cycle again. A more definite answer to this problem must await a dynamical model simulating the interaction of the two gyres.

^{10}Be-dating of a manganese crust from Central North Pacific and implications for ocean palaeocirculation

M. Segl*, A. Mangini*, G. Bonani†, H. J. Hofmann†, M. Nessi†, M. Suter†, W. Wölfli†, G. Friedrich‡, W. L. Plüger‡, A. Wiechowski‡ & J. Beer§

One of the most promising applications of the new ^{10}Be detection technique using accelerator mass spectrometry is the determination of growth rates of Mn-nodules and crusts[1–5]. Because the half life of cosmogenic ^{10}Be (1.5 Myr) is of the same order as the time needed for a few millimetres of nodule material to grow, ^{10}Be is a useful tool for unravelling such evolution during the late Tertiary, when most nodules are assumed to have started their growth[6]. Mass spectrometric measurement of a ^{10}Be profile across the manganese crust VA 13-2 from the Central Pacific, using a tandem van de Graaff accelerator, yields growth rates of 2.7 and 4.8 mm Myr^{-1} for the layers of the crust accumulated between Recent and 6 Myr BP and between 6 and 11 Myr, respectively. Using these measurements as well as ^{230}Th dating, we have been able to distinguish boundaries between zones in the crust with different structures and chemical compositions and to assign ages to them. These ages are 0.12, 2.9–3.4, 5.7–6.7, 7–9, 10–12 and 13–16 Myr BP. All of these boundaries apparently coincide with the times reported for Quaternary and late Tertiary palaeoclimatic events, suggesting that the crust growth has been strongly influenced by palaeoclimate.

During RV *Valdivia* cruise VA 13-2, 1976, a very thick ferromanganese crust (20–40 cm) was dredged near the summit of a submarine peak at a depth of 4,830 m in the Central Pacific[7,8]. In this crust, which directly overlies altered basaltic rock, three macroscopically distinguishable main zones (top zone, middle zone and bottom zone) and numerous subzones T-1 to T-6, M-1 to M-7 and I-1 to I-6 (from top to bottom) have been identified. The individual subzones, ~1–3 cm thick, are built up of macrolayers and microlayers showing a knob-like to cuspate texture similar to ferromanganese nodules. It was suggested that in the top zone (T-1 to T-6), where the ^{10}Be profile was measured, the Mn, Fe, Ni and Co and other trace elements came mainly from seawater. The Mn/Fe ratio indicates hydrogenetic growth all through the top zone[9], yet the content of Mn, Fe and of trace elements changes from one subzone to another.

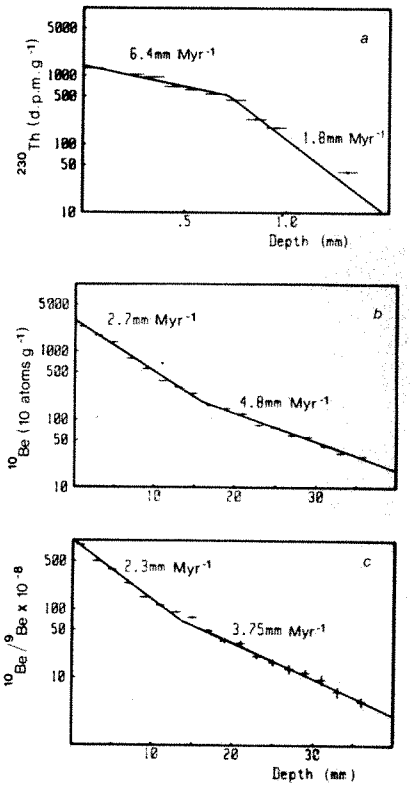

Fig. 1 *a*, ^{230}Th profile for the uppermost 1.4 mm of the crust. The exponential decrease yields growth rates of 6.4 mm Myr^{-1} for the uppermost 0.8 mm of the crust and 1.8 mm Myr^{-1} between 0.8 and 1.4 mm. *b*, ^{10}Be profile for the top zone of the crust. For the section between 0 and 16 mm the growth rate amounts to 2.7 mm Myr^{-1}, and between 16 and 38 mm to 4.8 mm Myr^{-1}. *c*, ^{10}Be/^{9}Be ratio for the top zone. It yields growth rates of 2.3 mm Myr^{-1} for the uppermost 16 mm and 3.75 mm Myr^{-1} for the depth-range 16–38 mm.

A closer look at the photomicrograph of polished sections (Fig. 3) reveals the existence of inner structure in excess of the one described by the T-1 to T-6 notation. This structure consists of a sequence of zones with 'pillar' or 'columnar' growth[8], labelled C1 to C3 and P1 to P3. We observe, for example, a clear change from pillar structure P1 to the columnar structure C2 at a depth of ~16 mm. A detritus-filled layer 16 mm from the top of the crust can be seen on the photomicro. Further layers are located at 6.5 and 22 mm (ref.8).

Samples for the ^{230}Th and ^{10}Be profiles as well as for chemical analyses of Mn, Fe, Co, ^{9}Be and Ni were taken perpendicularly to the surface using a drill bit of 1.0 cm^2 area, giving a continuous profile through the crust. Be and Th were purified using wet chromatography techniques,[2,3,10]. Th was electroplated and estimated by α-spectrometry. Be was ignited to form BeO and the ^{10}Be/^{9}Be ratios of 0.5 to 2 mg BeO samples were measured by mass spectrometry using the EN-tandem accelerator of the ETH-Zürich[11,12]. The stability of the mass spectrometer was verified by measurement of an internal standard[21]; reproducibility is better than 3%, but the absolute calibration has an uncertainty of ~10%. The sensitivity depends on the ^{10}Be contamination, which for most samples was at the p.p.m. level, leading to a background corresponding to a ^{10}Be/^{9}Be ratio of 10^{-14}. Growth rates were derived by applying half lives of 75,000 yr (^{230}Th) and 1.5 Myr (^{10}Be) and under the basic assumptions that: (1) ^{230}Th profiles and ^{10}Be/mass ratios or the ^{10}Be/^{9}Be ratio have been constant throughout time; (2) diffusion is negligible. In other words we assume that the profiles reflect only radioactive decay and crust growth.

^{230}Th yields a growth rate of 6.4 ± 0.5 mm Myr^{-1} for the uppermost 0.8 mm of the crust. Between 0.8 and 1.4 mm the growth rate amounts to 1.8 ± 0.12 mm Myr^{-1} (Fig. 1*a*). The significant change in growth rate at 0.8 mm is dated at 125,000 yr BP. The

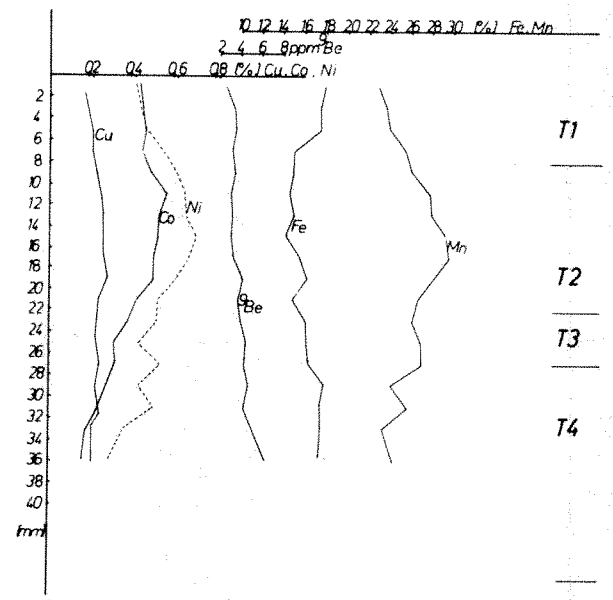

Fig. 2 Chemical composition of the top zone. The Mn content as well as the Ni content has a maximum at a depth of ≅16 mm. ^{9}Be shows a very slight but constant decrease from 4 p.p.m. at 30 mm to 3 p.p.m. at the surface, explaining why growth rates derived from the ^{10}Be/^{9}Be depth-profile are 20–30% smaller than those derived from the specific ^{10}Be content.

Table 1 Ages for boundaries of crust sections with different mineralogical structure

Boundary no.	Depth (mm)	Age (Myr)
1	0.8	0.125 ± 0.01
2	1.4	0.46 ± 0.04
C1/P1	8.0	2.9–3.4
P1/C2	15.5	5.7–6.7
C2/P2	23.0	7.8–9.1
C3/P3	36.0	10.0–12.0
Bottom of T6	42.0	11.0–14.0

Growth rates were derived from the ^{230}Th profile for the upper 1.4 mm and from the ^{10}Be-profile and the ^{10}Be/^{9}Be-ratio respectively for the deeper layers. The uncertainties of the ages result from the different growth rates calculated from the ^{10}Be/mass and ^{10}Be/^{9}Be-ratios, respectively (see Fig. 2).

^{10}Be, as well as the ^{10}Be/^{9}Be, depth profiles (Fig. 1*b*, *c*) show an exponential decrease and a clear change of the growth rate at 16 mm. The growth rate for the section 0–16 mm amounts to 2.7 ± 0.13 mm Myr^{-1} and 2.3 ± 0.2 Myr^{-1}, as derived from the ^{10}Be and ^{10}Be/^{9}Be profiles. For the section between 16 and 38 mm we derive growth rates of 4.8 ± 0.2 and 3.75 ± 0.25 mm Myr^{-1}, respectively. Applying these rates we are able to calculate ages for the boundaries of the crust sections with different texture as shown on Table 1 and Fig. 3. For comparison with other crust data from the Central Pacific[1,5,13], we compute fluxes of ^{10}Be and ^{230}Th on the surface of the crust to be 1.4×10^7 atoms ^{10}Be per cm^2 per 10^3 yr and 1.2 d.p.m. per cm^2 per 10^3 yr, derived as $F = G \times C \times D$, where G is the growth rate, C the element concentration at the surface and D the bulk density[13].

The smooth exponential decrease of the ^{10}Be/mass and ^{10}Be/^{9}Be profiles for individual larger sections as found on the crust VA 13-2 implies constant growth rate and ^{10}Be deposition. The results suggest constant ^{10}Be/carrier mass ratio for the past 11 Myr, the standard deviation from an exponential is <5%. This is a similar conclusion to Ku *et al.*[5] who reported evidence for constant deposition of ^{10}Be and ^{9}Be during the past 7–9 Myr for two analysed crusts from the Pacific and Atlantic Oceans. Further support for a constant ^{10}Be to mass ratio derived from VA 13-2 is (1) the numbers fit well Turekian *et al.*'s plot of the ^{10}Be flux against nodule growth rate on ^{10}Be dated nodules,

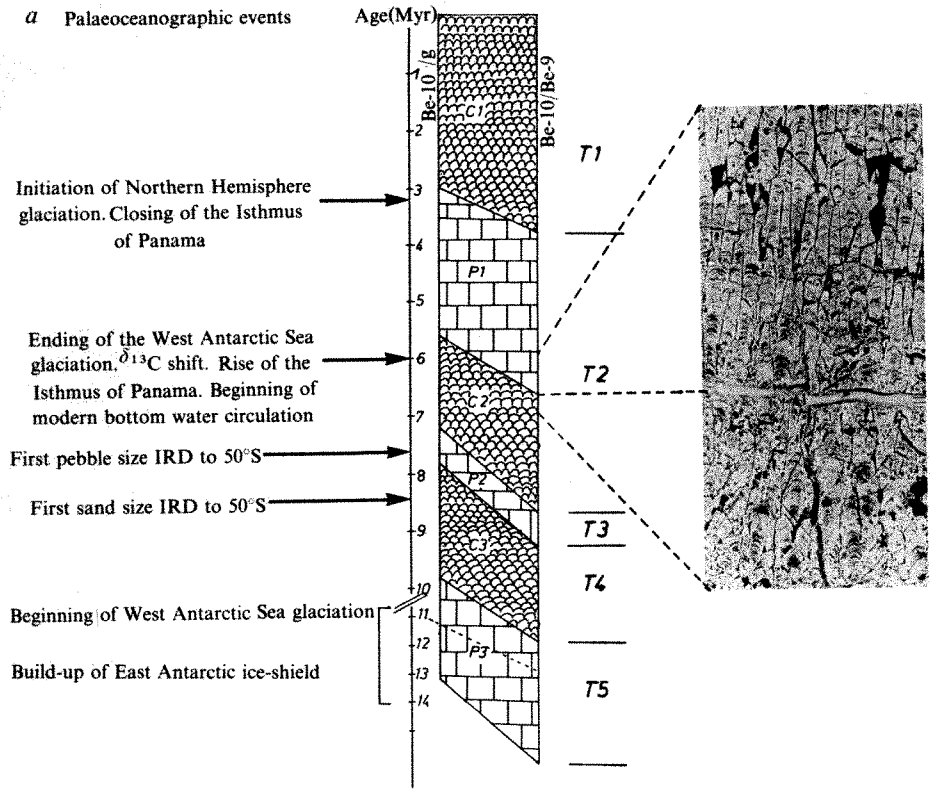

Fig. 3 *a*, Ages for the different sublayers of the top zone, calculated from the ^{10}Be-profile and from the ^{10}Be/^{9}Be ratio, respectively, and the palaeoceanographic time-markers during late Tertiary and early Quaternary. The uncertainties of the ages reflect the different growth rates derived from ^{10}Be/mass and ^{10}Be/^{9}Be ratios. *b*, Section of the photomicrograph showing the change from pillar to columnar structure P1 to C2 at 16 mm depth.

suggesting proportionality; (2) a 1.8-fold increase of the growth rate below 16 mm leads only to a different slope of the ^{10}Be depth profile and not to a significant offset of the specific ^{10}Be concentration.

One explanation would be to assume that in the water column the Mn carrier adsorbs an equilibrium amount of ^{10}Be, which is only a comparatively small fraction of the total available ^{10}Be (≅2.5%). Normalization of ^{10}Be against ^{9}Be has the advantage of making dispensable the assumption of a constant ^{10}Be to carrier ratio. It assumes, however, a constant ^{9}Be input to the open ocean and a constant concentration in seawater throughout time which, due to the comparatively short residence time of Be in the ocean, might be even more questionable than the constant ^{10}Be/mass assumption. A further crucial question is the extent to which the time record derived from the ^{10}Be depth profile may be distorted by diffusion within the crust. As has been pointed out earlier, diffusion, or diffusion associated with growth could also yield exponential depth profiles[3,4]. If we assume for the efficient diffusion coefficient of ^{10}Be an upper limit of 6.4×10^{-9} cm^2 yr^{-1} (ref. 14 and A.M., M.S., H. Kudraß, G.B., H.J.H., M.N., M.S. and W.W. in preparation), then <20% of the slope in crust VA 13-2 should be ascribed to diffusion, requiring a proportional correction of the time scale derived.

Table 2 Analytical data for Mn, Fe, Co, Ni, ^{9}Be and ^{10}Be and the ^{10}Be/^{9}Be ratio in the top zone of the crust VA 13-2

Depth (mm)	Mn (%)	Fe (%)	Co (%)	Ni (%)	Cu (%)	^{9}Be (p.p.m.)	^{10}Be (×10^7/g)	^{10}Be/^{9}Be (×10^{10})

Recent cross-calibrations showed that the Zürich Internal Standard yields 38% lower ^{10}Be concentrations than the standard at Rutgers University.

The data imply that the inner structure of the Mn crust may reflect global palaeoceanographic events. We shall therefore now discuss ages derived from VA 13-2 by taking as a frame of reference the comprehensive compilation of major Miocene to mid-Pleistocene events and episodes of Ciesielski *et al.*[15].

Sublayer T-1/T-2: The change from columnar zone C1 to pillar zone P1 is dated to 2.9–3.4 Myr, which corresponds with much evidence for beginning of the Northern Hemisphere glaciation[16].

Sublayer T-2: Structural change from pillar P1 to columnar C2 zone correlates with a different Mn-supply. The age of 5.7–6.7 Myr relates it to a most remarkable shift in δ^{13}C in the $CaCO_3$ in the Pacific Ocean dated to 6.2 Myr (refs 17–19). At this time the West Antarctic Sea glaciation ended giving rise to what is presumed to be the beginning of the modern bottom water circulation. Tectonic activities led to a rise of the Isthmus of Panama. This date also lies within the time period 7.4–6.2 Myr where Ciesielski *et al.*[15] assume that the main phase of erosion on the Maurice Ewing Bank occurred. Most remarkable at this boundary is the change of the growth rate as determined from ^{10}Be: this change in the growth pattern seems not to be an isolated phenomenom for VA 13-2. On the SCHW-1D crust from the Pacific dated by Ku *et al.*[5], the age of 6 Myr corresponds to layer 9.6 mm from the surface and lies within their sample 12 (9.12–10.7 mm). The flatter slope for a fit to the samples below 12 suggests that a shift in growth rate has occurred.

Evidence for a change in growth pattern at around 6 Myr BP is also recorded in several other Mn-encrustations from the North, Central and South Pacific[14].

Beyond sublayer T-2 there are three further clearly visible boundaries and changes from pillar and columnar structures that we date to 7.2–8.6, 7.8–9.1, and 10–12 Myr. Extrapolation of the ^{10}Be depth profile to 43 mm depth gives an age of 13–16 Myr BP for the basis of the top-layer. The first two markers in time could coincide with the occurrence of first pebble and

sand-size ice-rafted detritus to 50° S, on the Maurice Ewing Bank[15], which are considered to be an indicator for increased Antarctic Circumpolar Circulation (ACC). The growth of the top-zone apparently began with the build-up of the East-Antarctic ice-shield[20].

Finally, note that at sublayer T-1, at 0.8 mm from the surface (≅125,00 yr BP), where ^{230}Th indicates a remarkable variation in growth pattern, Mn begins a steady increase from ≅27% (the average for the uppermost 42 mm) to ≅35% by weight at the surface[8]. This might indicate a different and larger supply of Mn in the most recent history of the crust. Although the microprobe analysis shows that this is one of the largest variations of the Mn concentration over the last 11 Myr, we have to be aware that there might have been other short-term rate variations which we are not able to determine at the present stage of sampling resolution for ^{10}Be (≅800,000 yr).

A relationship between dunes, fire and climate recorded in the Holocene deposits of Quebec

Louise Filion

Département de Géographie and Centre d'études nordiques, Université Laval, Quebec, Canada G1K 7P4

During the past 5,000 yr BP the Tropics have experienced an increase in aridity and aeolian activity in both maritime and continental areas[1–4]. In contrast the onset and subsequent development of post-Hypsithermal climates in northern latitudes were primarily conducive to global cooling. It is suggested here that aeolian activity in cold environments represents a direct response to this long-term cooling trend that began after 6,000–5,000 yr BP, at the end of the climatic optimum[5–9]. This study establishes the Holocene chronology of sand dunes near the outer forest limit in northern Quebec (Fig. 1). I show here that fires initiate the aeolian activity, and that the fire–dune relationship is typical of cooling period. On this basis, a palaeoclimatic reconstruction since the climatic optimum is proposed.

The chronology of aeolian activity was based on 101 ^{14}C dates. Eighty-six organic horizons were sampled from dune palaeosols that contained discrete, non-mixed, coniferous and shrub-species charcoal, and the remaining samples were non-charred wood fragments found in dune blow-outs. The ^{14}C histogram (^{14}C yr) was constructed using the methods of Ochietti and Hillaire-Marcel[10]. Aeolian phases were established considering both the cumulative statistical weight frequency of ^{14}C dates and the distribution of individual ^{14}C dates (Fig. 2).

The histogram (Fig. 2) indicates that the aeolian activity in the study area over the past 5,000 yr BP occurred episodically. Aeolian recurrences are confined to 13 periods: 4,650, 4,200, 3,850, 3,550, 3,125, 2,875, 2,425, 2,075, 1,775, 1,475, 1,175, 575 and 175 yr BP. The time interval between aeolian activity peaks varied from 250 to 450 ^{14}C yr, except between 1,175 and 575 yr BP where it was about 600 ^{14}C yr. The histogram shows three major aeolian intervals: 3,250–2,750 yr BP, 1,650–1,050 yr BP, and 750 yr BP to present (these periods are shaded on Fig. 2). The last period was interrupted for a short time around 350 yr BP. Because of the limited number of ^{14}C dates, similar long-lasting periods cannot be confirmed before 3,300 yr BP.

Most of the dune palaeosols were Dystric Brunisols[11]. If present, the eluviated horizon was thin (Ae or Aej), less than 2 cm thick, above a more or less sesquioxide-rich Bm horizon (Fe + Al pyrophosphate). Only one palaeosol was found to present a Bf horizon typical of podsol. Selected soil profiles from the various phytogeographical zones of the study area are shown in Fig. 3. Although variable, illuviated sesquioxides found in dune palaeosols rarely exceeded a value of 0.15%. Higher values were obtained in some palaeosols developed during the 2,200–1,650 yr BP period (Fagnant Lake and Great Whale River sites, Fig. 3), suggesting favourable pedogenic conditions. In all the study sites, the original soil surface was pedogenically developed. In Burton Lake, Little Whale River and Clearwater Lake sites (Fig. 3), it was the bottom soil that presented the highest pyrophosphate values compared with the dune soils found above. The development of a soil profile within the original non-ablated surface is an indication that the deposit remained for some time in an undisturbed state allowing plant colonization and soil development to occur. The time-lag between the original deposit setting and the onset of aeolian activity varied from one site to another, depending on the rates of deglaciation and of the recession of the Tyrrell Sea[12]. Accumulation of aeolian deposits above the original surface was the result of an ecological disequilibrium in a previously stable morphosedimentary unit. Some palaeosols were frost-disturbed before their burial. Frost cracks varied from 10 to 125 cm in length within the organic and mineral horizons (such as Richmond Gulf, Fig. 3). These wedge-like cracks ranged between 5 and 10 cm in width at the top, and their vertical configuration was emphasized by iron stainings. They were probably caused by seasonal frost cracks[13] that were likely to have formed in a single season, in severe cold conditions in snow-free sites. Thawing caused local subsidence and subsequent discordant bedding. Another consequence of geliturbation was observed in some soil profiles as involuted features (Minto Lake, Fig. 3). All these frost structures were observed in the following dated palaeosols: 3,210 ± 90, 3,040 ± 215, 1,780 ± 90, 1,615 ± 100, 1,400 ± 160, 1,275 ± 90, 1,210 ± 80, 1,160 ± 80, and 1,040 ± 160 yr BP. The periods around 3,125 yr BP and between 1,650 and 1,050 yr BP were particularly conducive to frost action in soils. The northernmost sites of the study area (Clearwater Lake, Richmond Gulf, Minto Lake, Fig. 1) presented more frost-disturbed palaeosols than their southern counterparts.

The presence of many buried organic horizons in dune palaeosols suggests an alternation of stabilization stages by the plant cover and erosional stages. The number of alternations progressively decreases from the Boreal Forest Zone to the Arctic Tundra Zone. Higher frequencies (14 in Burton Lake site, Fig. 3) in forested areas (respectively the Boreal Zone and the Forest sub-Zone of the Forest Tundra, *sensu* Payette[14,15]) are an indication that aeolian activity was episodic and that dune stabilization was easier than in the Tundra Zone. North of the forest limit, dune landforms are the result of a more intense and long-lasting aeolian process[16]. In all the study sites, the buried organic horizons contained charcoal (mostly coniferous and shrub remains), suggesting a close relationship between fires and aeolian activity; fire incidence is especially conducive to erosion in rather sandy areas. Although no inference can be made about the absolute fire frequency during the Holocene, the decreasing number of buried horizons from the Boreal Forest

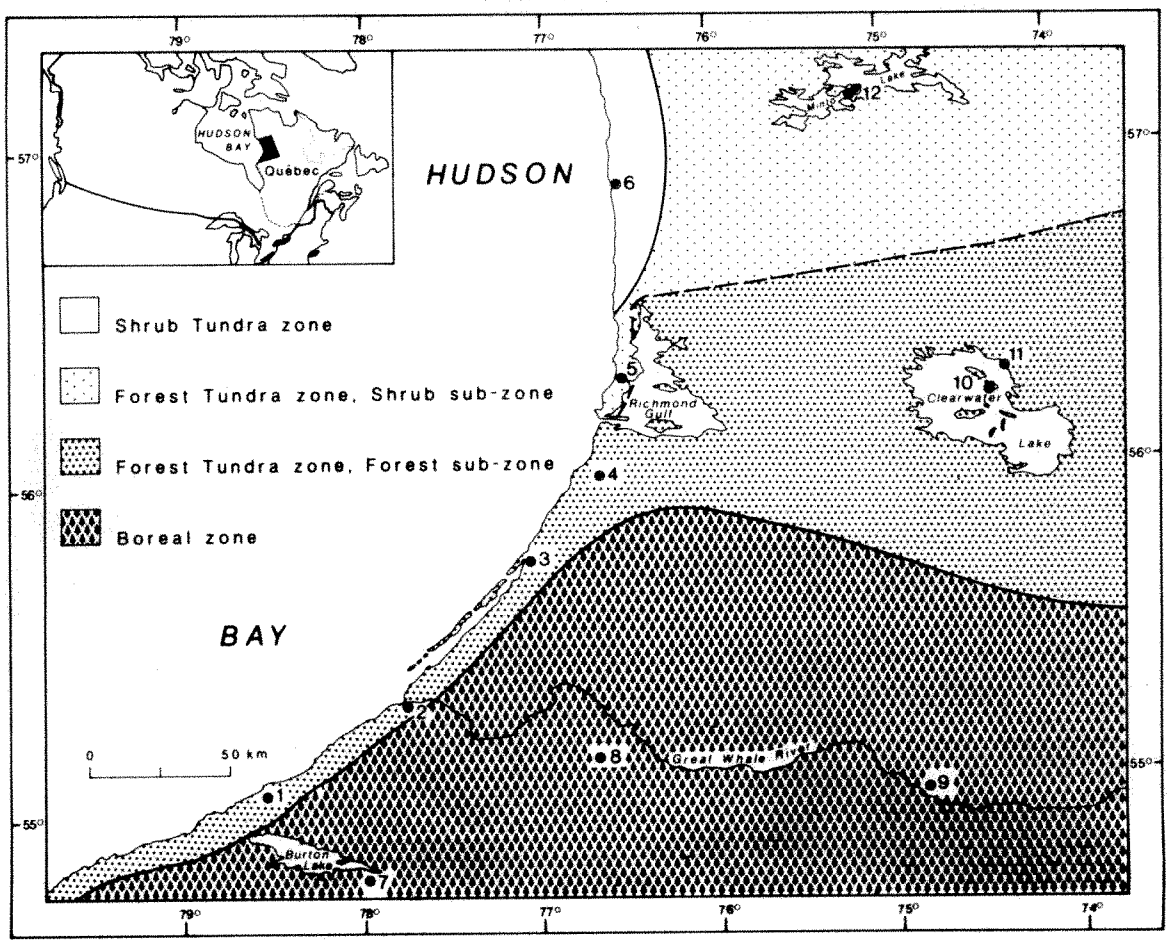

Fig. 1 Location of the study area and phytogeographical zones along the eastern coast of Hudson Bay (study sites: 1, Sucker Creek; 2, Poste-de-la-Baleine; 3, Manitounouk; 4, Little Whale River; 5, Richmond Gulf; 6, Nastapoka; 7, Burton Lake; 8, Fagnant Lake; 9, Great Whale River; 10, Ile-des-Foreurs–Clearwater Lake; 11, Nooniche–Clearwater Lake; 12, Minto Lake).

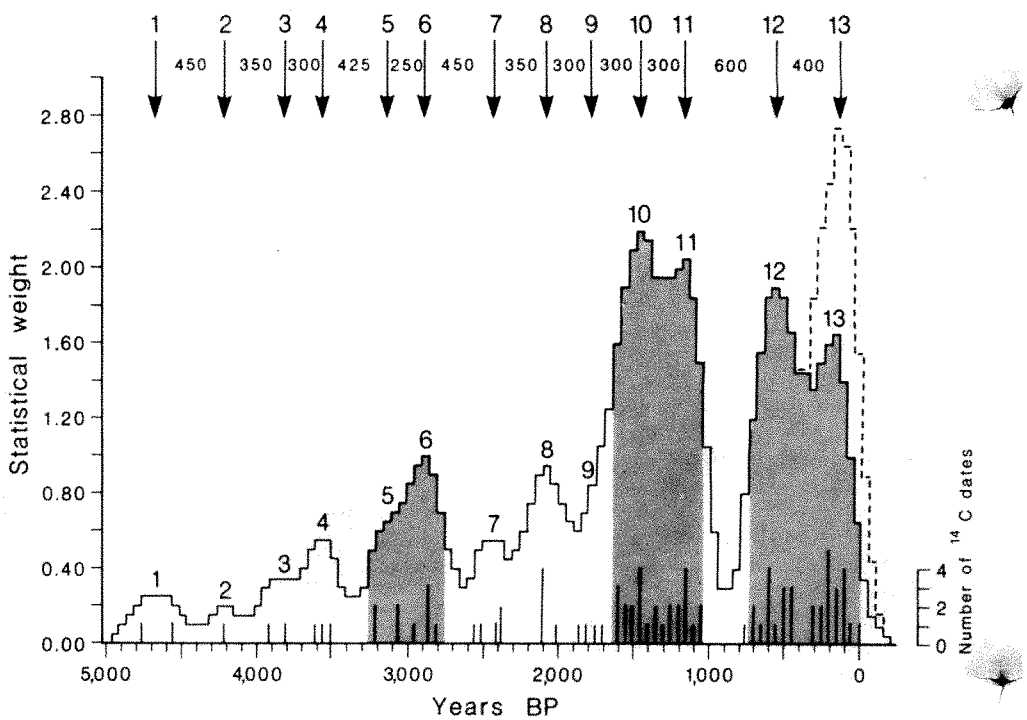

Fig. 2 Cumulative statistical weight histogram of the 101 ^{14}C dates from buried charcoal horizons (solid line) and non-charred wood fragments (dashed line). Also included the distribution of individual ^{14}C dates. Numbers from 1 to 13 refer to aeolian episodes, and shading indicates the three major aeolian episodes. The time-interval (^{14}C yr) between aeolian peaks is also presented.

to the Tundra emphasizes a decreasing gradient in fire incidence. Some long intervals of erosion-free activity, as, for example, in Little Whale River (3,610–1,160 yr BP) and Minto Lake (2,570–1,210 yr BP) sites (Fig. 3), could be the result of a lower fire frequency north of the forest limit which experienced only minor movements during the Holocene[17]. On the other hand, a detailed analysis of the regional chronologies[18] showed that greatest aeolian activity shifted from south to north between ~5,000 and

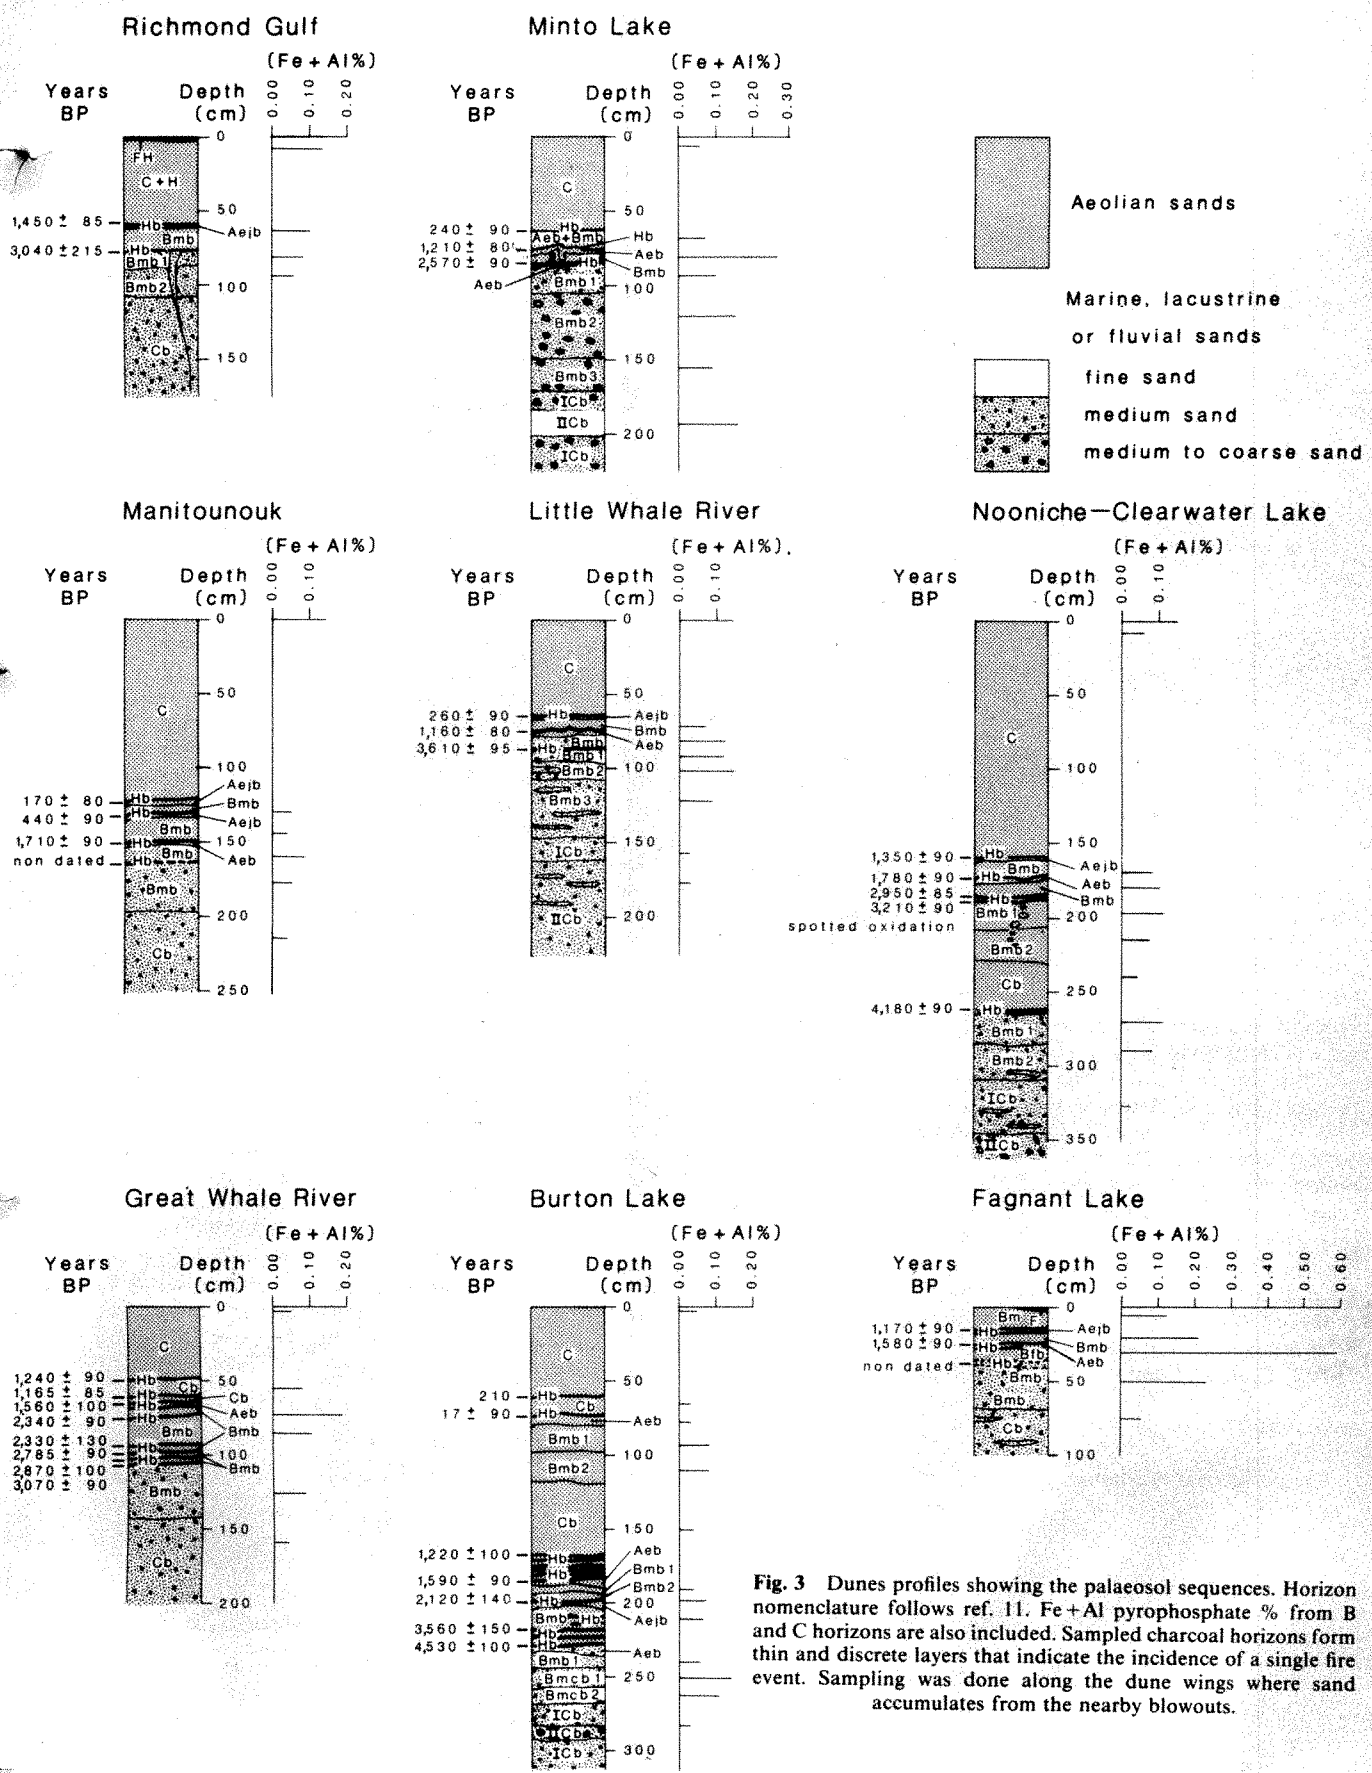

Fig. 3 Dunes profiles showing the palaeosol sequences. Horizon nomenclature follows ref. 11. Fe + Al pyrophosphate % from B and C horizons are also included. Sampled charcoal horizons form thin and discrete layers that indicate the incidence of a single fire event. Sampling was done along the dune wings where sand accumulates from the nearby blowouts.

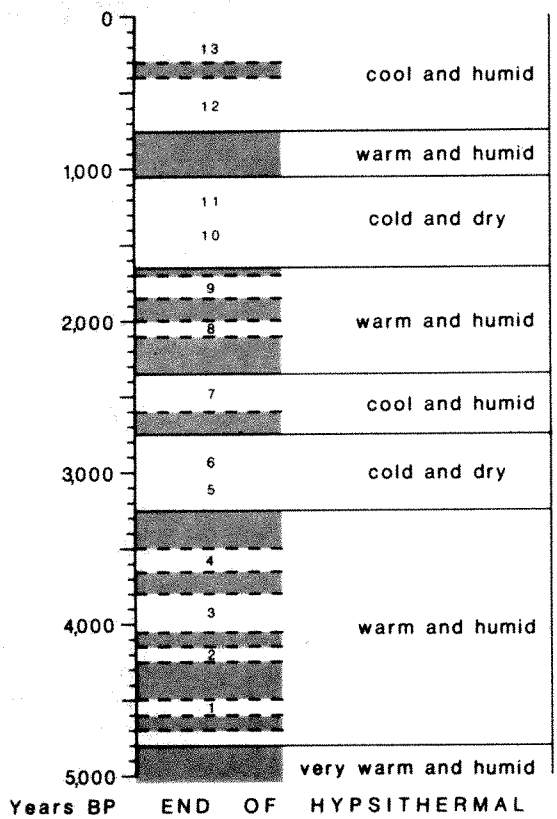
3,500 yr BP. Aeolian activity first started around 4,650 yr BP in the Boreal Zone sites, around 4,200 yr BP in the Forest Tundra, and finally reached the Tundra Zone around 3,850 yr BP. It thus came soon after the Hypsithermal in the Boreal Zone, whereas in the Tundra Zone it began only a thousand years later. This diachronism and south-to-north displacement probably resulted from a decrease in fire incidence from the Taiga to the Tundra. The areas located in the Northern Boreal Forest and in the



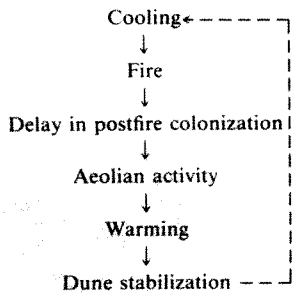


Fig. 4 Palaeoclimate reconstruction since the end of Hypsithermal. The periods delineated by a solid line are characterized by a distinct climatic regime, and the ones with a dashed line correspond to more clement (grey) and to cooling (white) intervals. Numbers 1 to 13 are the aeolian episodes.

Forest Tundra appear most appropriate for the study of aeolian activity during the Holocene, because here the forest biomass can be most conducive to the development of major fires. Here the fire frequency is relatively high, and post-fire colonization (dune stabilization) is more likely to occur during the warming periods and, inversely, may be compromised during cooling periods. Because they modify the structure of the plant landscape, fires influence the environmental equilibrium in such a way as to prevent forest regeneration. They seem to act as catalysts in inducing ecosystem change (for example, forest to dune shift) during cooling periods. This interpretation has been proposed elsewhere with regard to snow-patch expansion in northern Quebec[19], tundra-type vegetation expansion within the Forest Tundra[20], and Holocene displacements of the forest limit[17,21]. The development of aeolian systems in cold environments thus represents another ecological response to the fire-triggering process.

The periglacial aeolian cycle can be summarized as follows:

However, this cyclical model is not applicable to the tundra area. At those latitudes, aeolian systems follow a rather directional (secular) development. Climatic cooling after 3,000 yr BP in the Tundra was so important that dune stabilization was almost impossible even during brief warm periods[16,18].

Cold-region aeolian activity responds to the alternation of unfavourable climatic periods (peaks in Fig. 2) and favourable ones (lows in Fig. 2). Cold episodes follow the general, secular climatic cooling trend after the Hypsithermal (~5,000 yr BP), and became more important after 3,250 yr BP. Taking into account the fluctuations of the aeolian activity *per se*, it is possible to establish more precisely the climatic conditions that prevailed during the Holocene. Cold and dry conditions would be conducive to a significant increase of aeolian activity. The similar characteristics found in palaeosols related to the 3,250-2,750 yr BP and to the 1,650–1,050 yr BP periods are suggestive of such conditions. The presence of frost cracks during these periods would indicate severe cold conditions accentuated by a relatively dry climate (snow-free sites or with thin snow cover). Moreover, many palaeosols associated with these periods are related to a set of chronologically closely-bracketed organic horizons, emphasizing sustained erosional conditions probably after each forest fire (Burton Lake, Fig. 3, the 1,590–1,220 yr BP interval). Swain[22] also proposed that there were dry conditions in Wisconsin between 1,700 and 1,150 yr BP, based on pollen, macrofossil and charcoal evidence. A cool and humid climate would inversely decrease the aeolian activity. This trend is apparent between 2,750 and 2,350 yr BP (period 6–7, Fig. 2). The 750 yr BP to present period (episodes 12 and 13, Fig. 2) also registered a decrease compared with the 1,650–1,050 yr BP period (episodes 10 and 11, Fig. 2). This trend is more typical of maritime sites (Manitounouk, Little Whale River, Richmond Gulf, Fig. 1). More humid conditions may have accentuated the summer maritime ambiance along the Hudson Bay coast, thus reducing any fire and wind erosion probabilities (soil humidity increase). These two periods were also characterized globally by significant continental and alpine glacier expansions in mid- and high-latitude areas[6,23–25], and by snow-patch inception in northern Quebec[19]. A humid and warm climate would allow only local aeolian activity (4,800–3,250 yr BP, 2,350–1,650 yr BP) or would prevent it completely (Hypsithermal, and 1,050–750 yr BP). There is no evidence that a combined warm and dry climate ever existed at those latitudes. The palaeoclimatic reconstruction proposed here for the past 5,000 yr BP (Fig. 4), based on fluctuations of aeolian activity in northern Quebec, is presented as a first approximation. Nevertheless, it brings up the possibility of a cool/humid and cold/dry alternation in climate during the Holocene in northern, continental latitudes, as suggested by the long-term development of dune systems.

I thank the staff from the Laboratoire de Géochronologie for dating the samples, also Professors R. W. Fairbridge (New York), C. W. Finkl (Fort Lauderdale) and S. Payette (Quebec) for reviewing the original manuscript, and Professor P. Morisset for discussions. This research was supported by grants from the Natural Sciences and Engineering Research Council of Canada and by the Ministère de l'Education of Québec (FCAC Program).

A Gunflint type of microfossil assemblage from early Proterozoic stromatolitic cherts in China

Zhang Yun

Department of Geology, Beijing University, China

A well-preserved early Proterozoic microfossil assemblage dominated by a filamentous form comparable with *Gunflintia minuta* Barghoorn and a coccoid form comparable with *Huroniospora* Barghoorn has been discovered in silicified stratiform stromatolites of the Dahongyu Formation, Changcheng Group, northern Hebei Province, China. It is the oldest *in situ* microfossil assemblage in China. The famous Gunflint fossils, from the Gunflint Iron Formation, Ontario[1], were the first well preserved and relatively diverse Precambrian microbiota to be described[2,3]. Several other Precambrian microfossil assemblages are now known, but the Gunflint type has thus far been found in only a few other localities: the Duck Creek Dolomite, northwestern Australia[4]; the Frere Formation, western Australia[5]; and the Tyler Formation, northern Michigan, USA[6]. They are all early Proterozoic. The discovery indicates that the stromatolitic benthic microbiota of the Gunflint type had a cosmopolitan distribution in time between 2,000 and 1,700 Myr ago, and may have both palaeoecological and stratigraphical significance.

The sequence forms part of the northern North China Platform (Fig. 1). The fossil locality and the local geology have been described in detail elsewhere[7]. A generalized stratigraphy is given in Fig. 2. The early Proterozoic Changcheng Group consists of five formations (from the base up): (1) the Changzhougou Formation (conglomerate, sandstone and quartzite; ~170 m thick); (2) the Chuanlinggou Formation (oolitic and stromatolitic iron formation interbedded with carbonaceous shales; ~60 m thick); (3) the Tuanshanzhi Formation (dolostone, ~170 m thick); (4) the Dahongyu Formation (cherty dolostone, sandstone and lava; 110 m thick); (5) the Gaoyuzhuang Formation (cherty dolostone, ~1,000 m thick).

The Dahongyu Formation is composed of cherty dolostone, littoral to neritic sandstone, arkosic sandstone, tuffaceous sandstone–siltstone, volcanic breccia and potassium-rich trachyte. Several well preserved and distinct microfossil assemblages have been found in the lower and upper parts of this formation. The Gunflint type of microbiota occurs in the lower part of the Dahongyu Formation, in a zone 170–200 m above the top of the Chuanlinggou Iron Formation (Fig. 2). Glauconite from the middle part of the Dahongyu Formation in Jixien (eastern Hebei Province) has K–Ar ages of 1,621, 1,643 and 1,678 Myr. The U–Pb isochron ages of the upper part of the Tuanshanzhi Formation and the Chuanlinggou Formation (the underlying

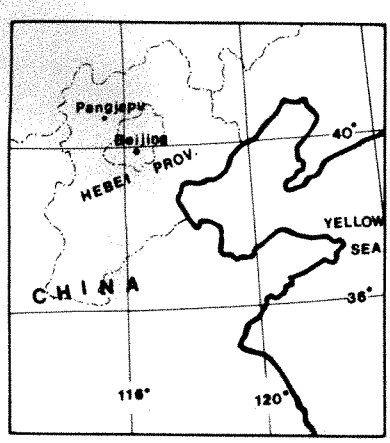

Fig. 1 Location of Pangjapu where the Gunflint type microbiota were discovered.

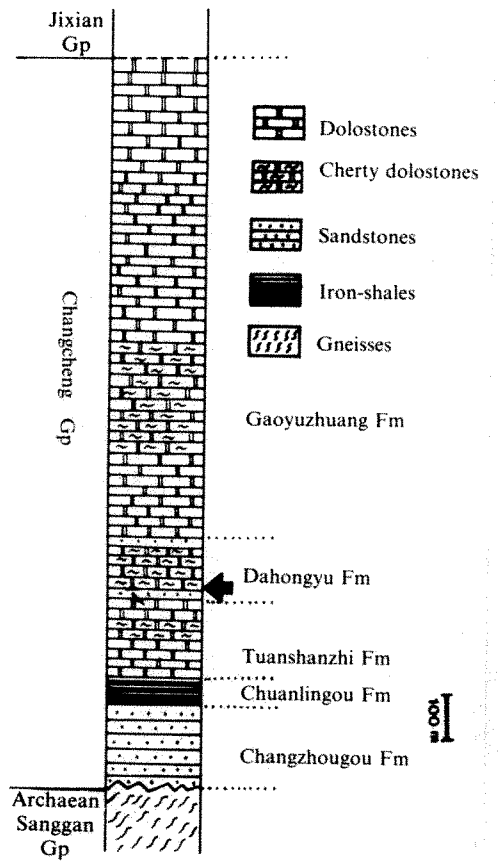

Fig. 2 Stratigraphical column of the early Proterozoic Changcheng Group in Pangjapu region. The arrow shows the position of the Dahongyu microbiota.

sediments) are 1,770 and 1,910 Myr respectively[8]. The age of the Dahongyu microbiota is therefore between 1,650 and 1,770 Myr.

The filaments of *G. minuta* and coccoids of *Huroniospora* sp. are usually found in stromatolitic organic-rich laminae. The filaments are gathered in bunches or intertwined with each other, often forming a network-like fabric (Fig. 3*a*, *b*, *f*, *k*). The coccoids are mostly scattered in spaces between the filaments. The distribution pattern of the Dahongyu microfossils is thus the same as that of the Gunflint stromatolitic microbiota from Schreiber, Ontario, suggesting that *G. minuta* and *Huroniospora* spp. were the principal mat builders.

The filaments of *G. minuta* from the Dahongyu Formation have diameters of 1–2 μm and are morphologically very similar to those from the Gunflint Iron Formation of Canada. The socalled 'heterocystous structures', that is occasional bulges in the filaments[1,9], have also been observed (Fig. 3*e*, *f*, *h*). It is possible that these structures were not original features of the *Gunflintia* organism, but instead have been caused by cell degradation. 'Budding' similar to that observed in the Gunflint Iron Formation[10] has been observed in the coccoids of the *Huroniospora* type from the Dahongyu Formation (Fig. 3*g*).

In addition to the two dominant forms mentioned above, some other rare filamentous and coccoid forms have been found (Fig. 3*i*, *j*). Some (Fig. 3*j*) can be assigned to Gunflint taxa such as *Leptoteichos golubicii* Knoll, Barghoorn et Awramik.

Two different facies of fossiliferous cherts have been recognized in the Gunflint Iron Formation: the stromatolitic chert facies containing the *G. minuta–Huroniospora* spp. dominated assemblage and the non-stromatolitic chert facies containing the *Kakabekia* and *Eoastrion* dominated assemblage[1]. The Dahongyu microbiota, dominated by *G. minuta* and *Huroniospora* spp., more closely resembles the stromatolitic benthic facies[1,2].

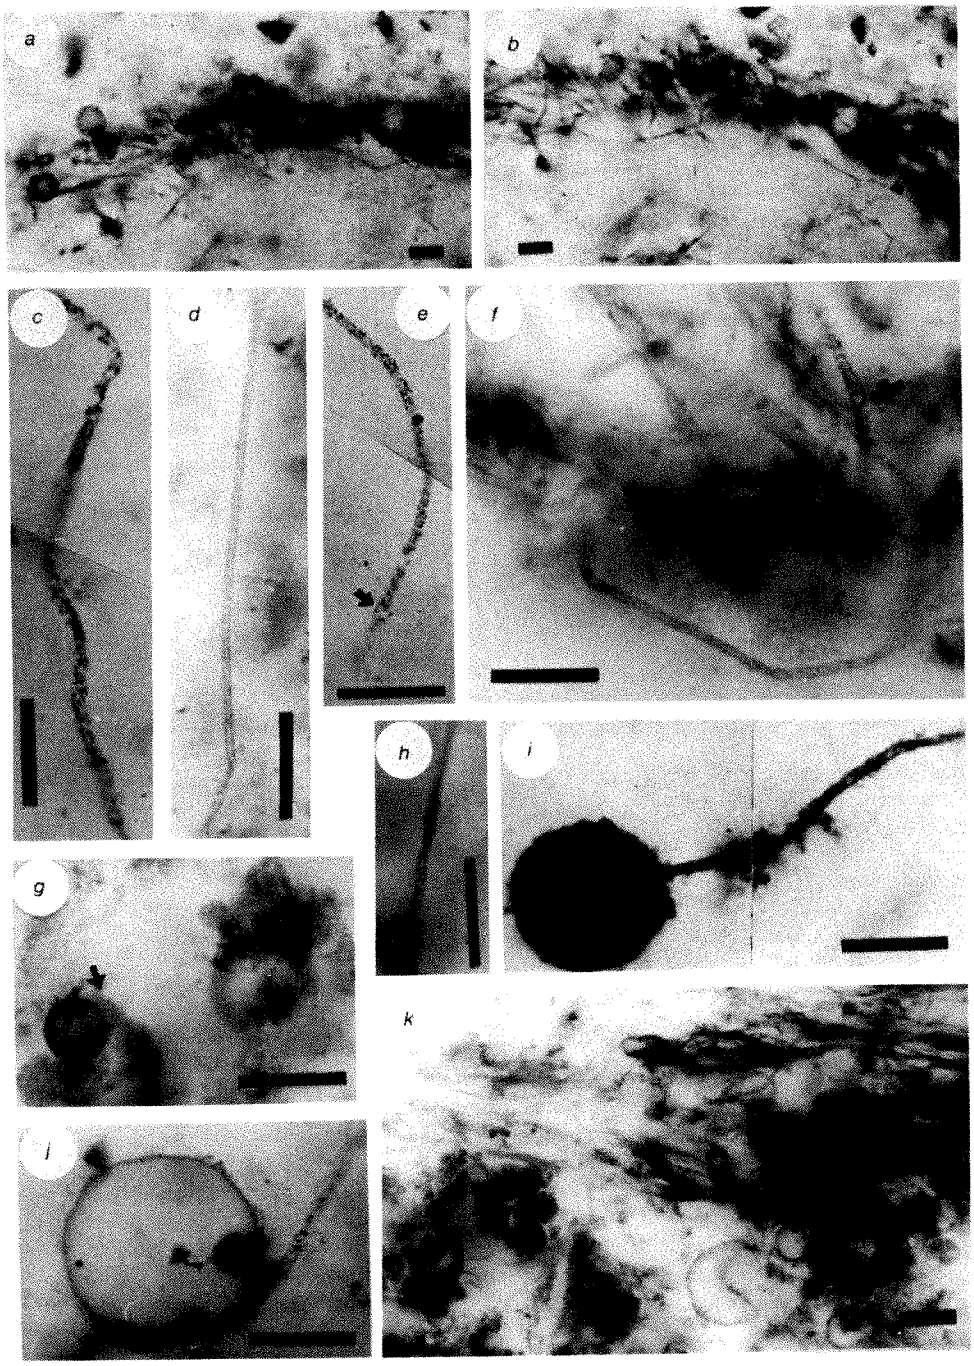

Fig. 3 Microfossils from the Dahongyu Formation. *a*, *b*, *k*, The gathered filaments of *Gunflintia minuta* and coccoids of *Huroniospora* spp, which constitute organic-rich stromatolitic laminae. *c*, *d*, *e*, *h*, *i*, *Gunflintia minuta* Barghoorn; the arrows indicate the bulges of the filaments which are similar to the 'heterocystous' structures and are probably caused by cell degradation. *g*, *j*, Some coccoid microfossils. *g*, A coccoid in budding (arrowed) similar to the budding coccoid *Huroniospora* spp. from the Gunflint Iron Formation, Ontario, Canda. *j*, A coccoid morphologically comparable with *Lepitoteichos golubicii* Knoll, Barghoorn and Awramik, a coccoid taxon from the Gunflint Iron Formation of Canada. Scale bar, 10 μm.

The discovery of a number of Precambrian microfossils over the past 20 yr has stimulated palaeontological research and raised hopes for using microfossils in studying the biostratigraphy of the Precambrian. These hopes have been tempered by the findings that some of the dominant Precambrain microorganisms show an apparent evolutionary conservatism and a considerable longevity in the fossil record. *Eoentophysalis* Hofmann[13], for example, persists for long periods and has a modern counterpart *Entophysalis*[14]. Nevertheless, other Precambrian microfossils and their assemblages appear to have been limited in time[4,15], and the Gunflint type of microbiota seems to belong to this kind. Hofmann noted the Belcher Island microbiota is significantly different from the almost contemporaneous Gunflint microbiota, but is quite similar to the microbiota from the Bitter Springs Formation, that is roughly half its age. He concluded that the Belcher and the Gunflint microbial assemblages must have lived in different environments[13].

The cherty dolostone beds in which the Dahongyu microbiota occur are intercalated with volcaniclastic sediments and lava, suggesting that the Dahongyu microbiota may have lived in a shallow marine environment in a region of volcanic activity. Evidence of contemporaneous volcanic activity is also found in the Gunflint Iron Formation and the Duck Creek Dolomite[4,16]. This suggests that the Gunflint type of microbiota may have been ecologically specialized[4,17] and may have lived in a unique environment related to volcanic activity.

The taxonomic affinity of most Gunflint microfossils has not well been defined. *Gunflintia minuta* may not necessarily be cyanobacteria, because the so-called 'heterocyst' or 'akinete' structures may be degradational artefacts, as mentioned above. The fine filaments of *G. minuta* are morphologically similar to some modern photosynthetic and thermophilic filamentous bacteria which live and build microbial mats or stromatolites at temperatures up to 70 °C in hot springs[17,18]. The budding coccoids of *Huroniospora* spp. with a wide range of diameter

(1–20 μm) may represent a taxonomically mixed population[1,6,10].

By comparing the Gunflint type microbiota from the Gunflint, Frere, Duck Creek, Tyler and Dahongyu Formations, we may conclude that: (1) *Gunflintia–Huroniospora* assemblage dominated a typically benthic mat-building microbial community that formed stratiform, columnar and spherical stromatolite morphotypes[12] in a particular range of environmental settings[4,13]. (2) The Gunflint type microbiota had a worldwide distribution in the middle Precambrian. Their fossilized remains are now found in present-day North America, Australia and China. (3) These organisms, as an assemblage association, occur within a limited time span of between about 2,000 and 1,700 Myr ago.

The discovery of the Dahongyu microbiota (the oldest *in situ* microfossil assemblage in China) provides new data for general Precambrian micropalaeontology. This supports the conclusion that these microorganisms, and possibly also the environmental conditions in which they flourished, were common and geographically widely distributed, although restricted to a relatively narrow time frame in the early Proterozoic. Thus the Gunflint type microfossil assemblage may have palaeoecological as well as biostratigraphical significance.

I thank Dr S. Golubic and Dr S. Campbell for help in revision of the manuscript, also Mr Ja Kehua and Mr Ni Debao for help with preparation of the thin sections.

The myth of the mad March hare

Anthony J. F. Holley* & Paul J. Greenwood†

* Ferndale, Wick Lane, Brent Knoll, Highbridge, Somerset TA9 4BU, UK
† Department of Adult and Continuing Education, University of Durham, Durham DH1 3JB, UK

From literature[1], proverb[2] and scientific publications[3–6], two aspects of the behaviour of the brown hare, *Lepus capensis*, are well known. First, they 'go mad' in March. Second, boxing is their most spectacular form of male–male competition for mates. Here we show that 'madness' is no more a feature of March than of the other months of their long breeding season, and that boxing does not represent intrasexual competition but an interaction between the sexes whereby a female attempts to prevent a male from mating. Finally, we discuss why misleading statements about hare behaviour have remained unchallenged for centuries.

The brown hare is a relatively solitary herbivore, feeding mainly at night[7]. The breeding season lasts from January to August, sometimes later, and each female may produce several litters per year[8,9]. Despite the length of the breeding season and the extensive overlap of male and female home ranges[10], it is traditionally claimed that male–male competition, in the form of chasing and boxing, peaks dramatically in March[1–6]. Indeed, scientific explanations for such activity have been offered[6].

From 1977 a population of hares has been studied on approximately 100 hectares of the flat, permanent pastures of the Somerset Levels, UK. Recordings were made from a vantage point 5 m above ground level. Data from over 1,500 hours of day and night-time observations by A.J.F.H. have been collected over 6 yr. From 1980 onwards, using an astronomical telescope giving magnifications of >100 times, and a catalogue of over 2,000 photographs of the hares, taken through the telescope, 10 males and 6 females have been recognized. Males and females are sexed by observation of male genitals and female teats. Individuals are recognized using features such as injury scars, facial markings and moult patterns.

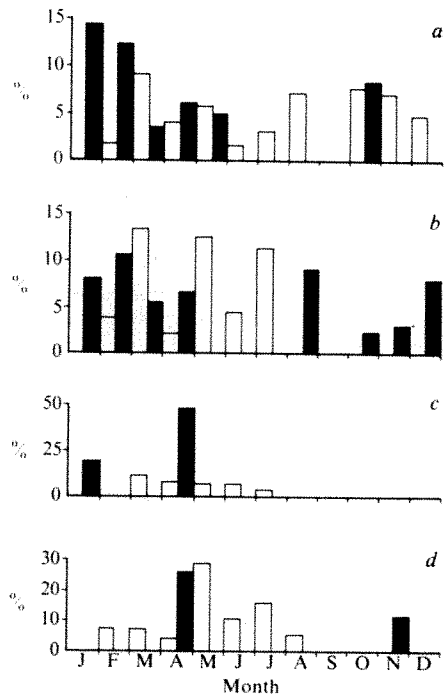

Fig. 1 The relative monthly and diel frequencies of types 1–4 (*a–d*, respectively) interactions throughout the year. Solid columns, sunset–sunrise, open columns, sunrise–sunset. Both diurnal and nocturnal samples have been standardized to take into account the amount of time spent observing each month. Cumulative hours of observation (1977–83) are as follows: January 112, February 123, March 158, April 167, May 177, June 181, July 271, August 120, September 32, October 96, November 67, December 63; total 1,567.

The different types of competitive, reproductive behaviour which occur between individuals are defined in Table 1, together with the totals of observed encounters distinguishing occasions when all individuals involved were recognized. Figure 1 shows the monthly and diel patterns of chase (types 1–3) and boxing. Of the total number of encounters, 82.1% occurred during the usual breeding period (January–August) but only 14% of the encounters were restricted to March. Of the remaining 86%, over half (52.4%) were observed at night. Nocturnal chases occurred significantly more often during winter months (October–March) than during summer months (April–September) ($\chi^2_1 = 16.31$, $P < 0.001$).

Five different females and six different males were identified for the 17 boxing bouts. In every case the boxing occurred between a female and a male; no intrasexual boxing has been observed. While we do not discount the possibility that such boxing may occur, this finding is supported by an independent, unpublished study in Oxfordshire where for each of 15 bouts in which both individuals were identified, a female–male interaction was involved (W. Reade, personal communication).

We have also studied a videotape of one prolonged boxing match lasting 1 min 59 s between a female (Camelia) and a male (Cadet) filmed by Simon King in late May 1982. During this interaction (counted as one event in the analysis) there was a sequence of 35 short, rapid chases: each chase by the male of the female alternated, as the male caught up with the female, with 34 separate boxes. In 24 cases, the female alone boxed,

Table 1 Summary of the categories of interaction between hares, the numbers observed and the occasions when all participants in an interaction were identified

		Total no. of interactions recorded	Interactions in which both or all hares were sexed and individually recognized† ♂→♂	♀→♂	♂→♀	♂♂♂→♀
Type 1 chases*:	High-speed chases between two adults which were not previously in close proximity to each other or another individual. When the hares were identified, three of four possible combinations by sex were recorded	55	8	4	2	–
Type 2 chases:	High-speed chases between two adults, one of which at the inception of the chase was in close proximity to a third adult. Chases frequently repeated. When hares were identified, one of the males was mate guarding a female and attempted to chase off the second male	69	46	0	0	–
Type 3 chases:	High-speed chases with more than two adults in a follow-my-leader arrangement. When hares were identified, several males were pursuing one female	8	–	–	–	4
Type 4, boxing:	One hare lunging frontally at another with its forepaws, usually from an upright bipedal position. A boxing bout sometimes consisted of an alternating sequence of boxing and short rapid chases	25	0	♀⇆♂ 17		–

* Type 1 chases were brief and not repeated and provided limited opportunity for individual recognition.
† Arrow indicates direction of chase.

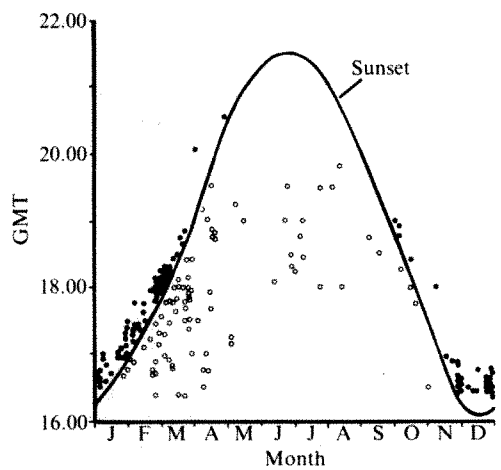

Fig. 2 Individual records (1977–83) of the times that hares were observed to leave their daytime forms in relation to the time of sunset throughout the year. This emergence from forms is equivalent to the onset of activity. ●, After sunset; ○, before sunset.

beating the head of the male with her paws as he lunged forward beneath her. In eight cases the two hares started boxing simultaneously while in the remaining two cases the male started to box after the female had initiated. In neither this case nor the other 24 boxing bouts did mating occur at the end of the encounter.

The classical view of hare 'madness' has been one of a frenzied but short period of male fighting and chasing. Indeed during the nineteenth century this episode in March was referred to as a rut[2]. On theoretical grounds such intensive behaviours should occur in polygynous species where females are available for mating for only a short, synchronous period[11]. The fact that the hare's breeding season is prolonged and involves several litters per female with limited reproductive synchrony should have suggested an anomaly in the behaviour of males, which would be expected to compete for mates throughout the breeding season—our results support that expectation. Clearly, much of the hare's behaviour has been overlooked. Early in the year this is probably because most interactions are nocturnal (Fig. 1): this viewpoint is supported by Fig. 2. The fact that hares leave their resting places (forms) in the early evening throughout the year means that activity in winter starts significantly more often after sunset than in the summer ($\chi^2_1 = 36.3$, $P < 0.001$). In the summer, behaviour patterns are probably overlooked because the length of grass restricts an observer's view from ground level. In the present study a high observation point and flat terrain minimized that problem.

Previously, boxing was regarded as a form of male–male competition for mates. In our study all such interactions were between a female and a male. We do not yet know whether the sex difference in boxing intensity in the filmed bout is reflected in the species as a whole, but it is worth noting that females are both larger and heavier than males and in the study population males frequently have injury scars to their ears.

In view of the results presented here, we offer a tentative, short appraisal of hare breeding behaviour. Early in the year males begin to chase other males and start to search for females. A male will guard a female prior to mating and will attempt to chase away other males. If there are several males close to an oestrous female, all of them, including the guarding male, may become involved in a mating chase. Boxing is the means by which a female may prevent either a particular male from mating with her or, when not in oestrus, any male from mating. This pattern of behaviour continues throughout the long breeding season. With apologies to Lewis Carroll, the March hare is a myth.

We thank Winwood Reade for her observation, Simon King for his videotape of the boxing bout between Camelia and Cadet, and Paul Harvey for his advice.

Spider silk as rubber

John M. Gosline*, Mark W. Denny† & M. Edwin DeMont*

* Department of Zoology, University of British Columbia, Vancouver, British Columbia, Canada V6T 2A9
† Hopkins Marine Station, Stanford University, Pacific Grove, California 93850, USA

The silks produced by spiders are exceptional structural materials. Although their tensile strengths are similar to those of cellulose, collagen and chitin, their extensibilities are considerably greater[1,2]. Thus, the energy required to break spider silk (that is, its toughness) can be 10 times greater than for these other biological materials. The silks are crystalline proteins, with substantial portions of their polypeptide chains forming crystallites of stacked β-pleated sheets[3–6]. However, the extensibility of silk is attributed to non-crystalline regions, which appear amorphous on X-ray diffraction[7,8]. The mechanical properties and macromolecular conformation of these amorphous regions have been the subject of much speculation[1,2,7–10], but little direct experimentation. Here we show that these regions can behave as rubber networks and exhibit rubber-like or entropy elasticity.

At room temperature (~20 °C, 50% relative humidity) the silk produced by the major ampullate gland (dragline silk) of the spider *Araneus diadematus* is very stiff. If, however, an unrestrained segment is immersed in water it absorbs water and contracts to about 55% of its dry length[9,10]. This hydration-induced contraction is accompanied by a drastic reduction in elastic modulus from $\sim 10^{10}$ N m^{-2} to $\sim 10^{7}$ N m^{-2}, and a large increase in extensibility. These properties suggest that contracted silk is a protein rubber. X-ray diffraction, however, indicates that the crystalline regions are relatively unaffected by this contraction[9]. The interchain crystal dimensions are unchanged and analysis of diffraction intensities indicates that the crystals reorient but are not substantially melted. Thus, contracted silk appears to be a protein rubber filled with crystalline inclusions.

A rubber is composed of a large number of kinetically free, random polymer chains that are cross-linked to form a macroscopic network. The elasticity of such a network is due primarily to changes in the conformational entropy of the polymer chains, and only secondarily to changes in internal energy[11]. In contrast, stiff solids such as steel, store elastic energy as changes in internal energy associated with the distortion of chemical bonds. We have used thermoelastic measurements to determine the relative importance of internal energy and conformational entropy changes in the elasticity of contracted spider's silk. The elastic force (f) for a material deformed as a closed system at constant volume (V) and temperature (T) can be expressed in terms of changes in internal energy (E) and entropy (S), as follows[11]:

$$f = (\partial E/\partial L)_{T,V,n} + T(\partial f/\partial T)_{L,V,n} \quad (1)$$

where L is the length and n indicates constant composition. Thus, the slope of a force–temperature plot at constant length and volume and fixed composition, $(\partial f/\partial T)_{L,V,n}$, multiplied by temperature gives the desired conformational entropy component of the elastic force (f_S), and the intercept of the force–temperature plot, $(\partial E/\partial T)_{T,V,n}$, gives the internal energy component (f_E).

In practice, it is nearly impossible to maintain constant volume and fixed composition in a thermoelastic experiment because the swelling of a sample held in equilibrium with a swelling solvent can vary with temperature. A thermoelastic relationship written for the conditions of constant pressure (P) and swelling equilibrium (eq),

$$f = (\partial H/\partial L)_{T,P,\mathrm{eq}} + T(\partial f/\partial T)_{L,P,\mathrm{eq}} \quad (2)$$

yields entropy and enthalpy (H) components, which contain contributions from network chain conformational changes and

a, The results calculated for contracted spider's silk, as described in the text: f_H/f was calculated from equation 2, as the intercept (at 0 K) of the uncorrected stress–temperature plot, divided by the stress at 30 °C (303 K). f_E/f was calculated from equation 3 using the data corrected to give stress at constant extension ratio. The error estimates were derived from standard errors calculated from the regression statistics for the stress–temperature and length–temperature data. The modulus values were calculated by dividing the stress at 30 °C at each extension by the strain (strain = $\alpha - 1$), to give an indication of the stiffness of contracted silk. *b*, Some selected values for the internal energy component of the elastic force for natural and synthetic rubbers. (Data from ref. 13.)

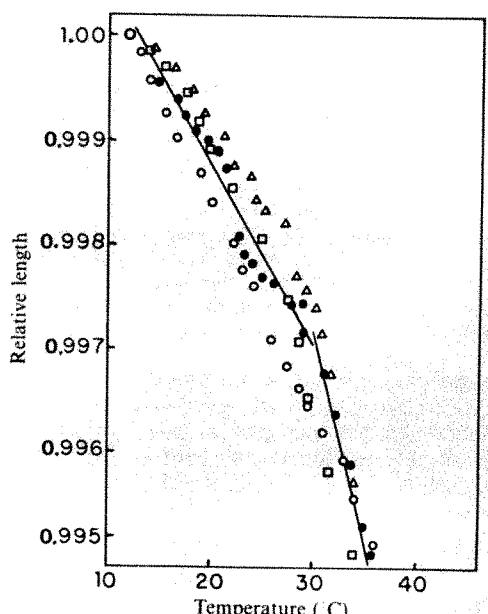

Fig. 1 Relative length versus temperature for four ~2.5-cm long samples of dragline silk immersed in distilled water. The relative length appears to decrease linearly with temperature over the range 10–30 °C, and linear regression analysis of all data up to 30 °C indicates a coefficient of linear expansion of -1.8×10^{-4} °C^{-1} ($R^2 = 0.923$, $n = 50$). Above 30 °C the magnitude of the swelling change appears to increase significantly, and regression analysis of all data above 30 °C yields an expansion coefficient of -3.9×10^{-4} °C^{-1} ($R^2 = 0.855$, $n = 15$). The cause of this change in swelling behaviour at around 30 °C is unknown, but to avoid problems we restricted our thermoelastic measurements to the region of linear behaviour between 10 and 30 °C. Swelling in this range is assumed to be isotropic, but this assumption was not tested due to the small swelling coefficient and the small diameter of the silk fibres (~5 μm).

Methods: Samples were suspended vertically in a cuvette made from microscope slides and held extended at essentially zero force by the weight of a glass rod (~ 5 mm long, 0.1 mm diameter) glued to the free end of the silk fibre. The weight of the rod caused an extension of less than 0.3%, and its effect is ignored. Changes in the length of the silk fibre were observed by following the vertical movement of its free end with a filar micrometer eyepiece on a Wild M5 dissecting microscope. The cuvette was mounted on a temperature-controlled stage and temperatures were measured (±0.5 °C) with a thermistor placed near the sample.

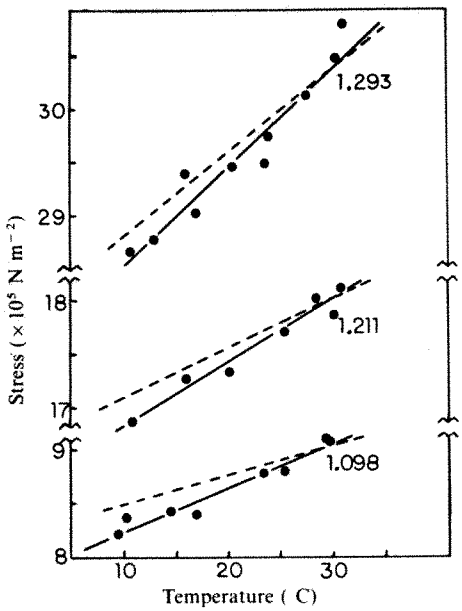

Fig. 2 Thermoelastic data for dragline silk immersed in distilled water and extended to the extension ratios indicated. Samples (~2 cm long) were mounted on a test frame, described previously[16], in which the force is determined by following the deflection of a thin (~0.1 mm diameter) glass beam. The beam deflection was measured with a filar micrometer eyepiece on a Wild M5 dissecting microscope, and sample temperature was maintained and measured as described for Fig. 1. The silk sample was extended to its test length at the highest temperature (~30 °C) and allowed to relax for about 1 h. The temperature was then lowered in stages to ~10 °C, raised in stages to ~30 °C and lowered again to ~10 °C. The forces at each temperature were calculated from the mean of 6–10 determinations of beam deflection, and in all cases the standard error was roughly the size of the point plotted. The solid lines indicate the linear regression of the data (correlation coefficients, R^2, are all greater than 0.91). The broken lines indicate the regression line corrected to give stress at constant extension ratio. The corrected data were used with equation 3 to calculate f_E/f.

also from polymer-solvent mixing processes. To determine f_E and f_S for contracted spider's silk we have used constant-pressure measurements, and then corrected for swelling changes by calculating the force–temperature coefficient at constant extension ratio (α = extended length/initial length), using the following relationship[12];

$$f_E/f = -T\left(\frac{\partial \ln (f/T)}{\partial T}\right)_{P,\alpha,eq} + T\lambda_s \qquad (3)$$

where f_E/f represents the fraction of the force due to changes in internal energy, and λ_s is the coefficient of linear thermal expansion. Because this swelling correction assumes that swelling changes are isotropic, the calculated f_E/f values are reasonable approximations but are not exact.

Figure 1 shows length–temperature data for contracted silk, from which λ_s is calculated as -1.8×10^{-4} °C^{-1} between 10 and 30 °C. Figure 2 shows the results of thermoelastic measurements on contracted silk at three extensions. The force values are divided by the initial cross-sectional area to give a value for stress. For each extension the solid line shows the linear regression of the data; the broken line is this regression corrected for the effects of swelling to give the stress at constant extension ratio, with 30 °C taken as the reference.

Table 1 gives the enthalpy (f_H/f; equation 2) and internal energy (f_E/f; equation 3) components of the elastic force calculated from our data. The enthalpy (that is uncorrected) component of the elastic force is negative at low extensions and becomes increasingly positive as extension increases. It is unlikely that the amorphous chains crystallize with extension because the enthalpy component, which would be negative for such a strain-induced crystallization, becomes positive as extension increases. Rather, the negative enthalpy component at low extensions arises from the thermal-swelling behaviour of the material. When the data are corrected for swelling effects, the internal energy component (f_E/f) becomes a small and essentially constant, positive fraction of the elastic force. The average f_E/f value of 0.14 is similar to that seen for other rubbery materials (Table 1*b*)[13], and indicates that roughly 85% of the retractive force of contracted spider's silk is due to changes in polymer chain conformational entropy.

The thermodynamic properties of contracted dragline silk indicate that the material is a rubber. Apparently, when immersed in water the protein chains in the amorphous regions have sufficient kinetic freedom so that bulk deformations do not cause any major changes in bond energy potentials. Rather, energy is stored primarily as a change in the conformational entropy of these chains. The crystalline regions presumably serve to cross-link the amorphous chains into a network. This proposed structure for contracted (that is, hydrated) silk may shed important light on the behaviour of the silk in its normal, non-contracted state. Protein rubbers in general are rubbery only when swollen in water or some other polar solvent[14]. A lowered water content decreases kinetic freedom of the peptide chains, and the material enters its glass transition, where stiffness increases dramatically, extensibility is reduced, and viscoelastic energy dissipation becomes very important[14]. We propose that the dragline silk of *A. diadematus* in room conditions should be thought of as a rubber that functions near the middle of its glass transition. The amorphous regions provide a reasonably stiff, energy-absorbing matrix within which are embedded very stiff, crystalline inclusions. In this respect silk, like nylon, is a fibre-reinforced composite, and the analysis of silks as composite materials may well explain their unusually high breaking energies[15].

We thank Dr C. Dondale, Biosystematics Research Institute, Agriculture, Canada for identifying our spiders. This research was supported by NSERC grant 67-6934 to J.M.G.

Inability of Rous sarcoma virus to cause sarcomas in the avian embryo

David S. Dolberg & Mina J. Bissell

Laboratory of Cell Biology, Division of Biology and Medicine, Lawrence Berkeley Laboratory, University of California, Berkeley, California 94720, USA

The injection of Rous sarcoma virus (RSV) into the wing web of newly hatched chicks causes a rapidly growing sarcomatous tumour which is palpable within 1 week of inoculation[1]; and cultures of fibroblasts derived from chick embryos (CEF) and infected with RSV become rapidly transformed[2]. Genetic studies have determined that expression of a single viral gene, designated v-*src*, is necessary for neoplastic transformation[3]. This gene codes for a 60,000-molecular weight phosphoprotein termed pp60^{src}, which

possesses a protein kinase activity that phosphorylates polypeptides on tyrosine residues and is constitutively expressed in infected CEF cells[4]. It has been suggested that transformation, and possibly tumorigenesis, may result solely from the consequences of this increase in tyrosine phosphorylations[4]. The pathogenicity of RSV in chick embryos *in ovo* is less clear. Murphy and Rous[5] suggested that RSV may have caused tumours in "various tissues" of "some embryos", but the subsequent studies of Milford and Duran-Reynals[6], as well as several other laboratories[7,8], failed to find any evidence of intraembryonic tumours in RSV-infected early embryos. The findings of Duran-Reynals, if correct, cannot be explained easily in view of our present understanding of RSV tumorigenicity. Thus, we have re-examined the interaction of RSV with the avian embryo and confirm here that RSV is non-tumorigenic and non-teratogenic when microinjected into day 4 chicken embryos. In addition, we found that (1) the virus not only replicates in the embryo, but it also expresses an active *src*-specific protein kinase and (2) once the cells from the infected limbs are disrupted and placed in culture, they are capable of expressing the transformed phenotype after a 24-h delay.

Using a capillary tube pulled to 40–75 μm diameter, we inoculated the limb bud of day 4 chicken embryos (stage 22–24)[9] with 10^4–10^5 focus-forming units of Prague-A (PRA) or Schmidt–Ruppin-D (SRD) RSV. Control embryos were inoculated with virus-free medium (medium 199 supplemented with 2% tryptose phosphate broth, 2% fetal calf serum and 1% chick serum—designated medium 2-2-1). Embryos were allowed to continue *in ovo* and eggs were candled daily. Some embryos were killed and analysed at various developmental stages; others were examined at death. We found no appreciable difference between the survival of control and virus-inoculated embryos until 7 days post-injection when the mortality of virus-inoculated embryos increased relative to the inoculated controls, suggesting that events specific to the virus infection had subsequently begun to manifest themselves (data not shown).

To date we have inoculated over 1,500 embryos. Those examined for tissue histology and gross morphology at various times during development showed no indication of neoplastic growth or teratogenesis. Figure 1*d*, *e* shows an example of a limb bud from a 14-day embryo which had been inoculated with virus on day 4. By morphological criteria, chondrogenic and myogenic differentiation are unimpaired. A section through the limb bud of an embryo inoculated with medium alone is presented for comparison (Fig. 1*a*). 25% of the RSV-containing embryos developed blood blisters that varied in size from 1 to 10 mm and resembled the non-neoplastic haemorrhagic lesions first described by Duran-Reynals[6,10] (Fig. 1*b*, *c*). No lesions were observed in control inoculated embryos, nor in embryos infected with transformation-defective (*td*) RSV (not shown).

The absence of response to RSV in embryonic limb buds contrasted sharply with the response in the wing of newborn chicks. As demonstrated by others[1,11], we found that, within 10 days, 75% of the newborn chicks inoculated with 10^4 FFU of RSV has palpable tumours, >5 mm in diameter. Furthermore, as few as 10 FFU generated tumours in 15% of the birds within the same time frame. The histological appearance of haemorrhagic lesions was easily distinguishable from that of RSV-generated tumour tissue taken from a 10-day-old chick inoculated 24 h after hatching (compare Fig. 1*b* and *c* with *f*). The tumour tissue was invasive and contained a heterogeneous population of cells with large irregular nuclei characteristic of neoplastic tissue. As we used cloned viruses and specific pathogen-free (SPF) eggs, we have essentially ruled out artefacts of possible interference by endogenous or exogenous viral contaminants. The results confirm those of Duran-Reynals and others[6,7,10], and suggest that early embryos are indeed refractory to the tumorigenic potential of RSV.

To determine whether or not RSV replicates *in ovo*, control and infected embryos were killed on day 14, and various tissues were homogenized and screened for the presence of reverse transcriptase[12]. We found more than a 10-fold increase in activity of the enzyme in the inoculated limb tissues, and a significant increase of activity in tissues distal to the infected limb bud (Table 1*a*). Virus from these embryos formed up to 2×10^5 FFU per μg of tissue DNA. Tissue isolated from 10-day-old tumours in young chicks contained $0{\cdot}5$–2×10^6 FFU per μg of DNA. It should be pointed out that as we neither observed an obvious tumour nor assayed the entire wing, some cells may not be infected. On the other hand, tissue taken from the tumours in the newborn, by definition, was viraemic. Some virus-inoculated embryos did not show the presence of virus when screened at day 14; we presume that, in these embryos, the injection was unsuccessful.

Despite the absence of tumours, tissues from infected embryos contained elevated levels of viral kinase activity, at times comparable with the levels found in tumour tissue. The level of kinase activity varied among embryos, but in the inoculated limbs there were increases as high as 50-fold compared with control tissues. Other tissues also contained elevated levels of kinase activity, suggesting that the infection had spread throughout the embryo. Elevation of kinase activity was detectable as early as 2 days after inoculation; therefore, full viral gene expression probably occurred soon after infection.

Table 1 Parameters associated with virus production in RSV-infected embryos

a Reverse transcriptase activity

Tissue	Fold increase
Plasma	2.4
Wing	10.1
Breast	3.0
Viscera	1.6
Brain	2.1

b Infectious virus and kinase activity

	Uninfected	Infected	Tumour tissue
FFU $\times 10^{-5}$ per μg DNA	0	1.3 ± 0.8	11.3 ± 57
Kinase per μg DNA	7.5 ± 2.1	190 ± 83	282 ± 57

c Distribution of kinase activity

Tissue	Fold increase
Infected wing	51.00
Liver	2.7
Opposed wing	3.7

Embryos were inoculated as described in the text, killed on day 14 and tissues were immediately frozen in a dry ice bath. *a*, Tissues were subsequently homogenized in 1.5 ml of 10 mM Tris, 1 mM EDTA. 0.05 ml of each tissue specimen was assayed for reverse transcriptase activity according to the procedure of Tereba and Murti[12], and 0.1 ml was assayed for DNA content by the method of Hinegardner[42]. Fold increase is the ratio of reverse transcriptase activity (normalized to DNA) in the tissues of virus-inoculated embryos compared with the normalized reverse transcriptase activity in the corresponding tissue of controls. *b*, Tissues were prepared as in *a* except that, for kinase analysis, they were homogenized in disruption buffer (25 mM HEPES buffer (*p*H 6.8), 1% Nonidet P-40, 0.5 M NaCl, 5 mM EDTA and 2% Trasylol). Kinase assays were done as described[43] except that the reaction buffer was 10 mM HEPES, 5 mM $MnCl_2$, 16 mM NaCl. Each sample was also assayed for DNA content as described[42]. Focus-forming activity was determined as described elsewhere[44] and normalized to the DNA content of the same tissue. Kinase activity was quantified by solubilizing the IgG band, counting the radioactivity and normalizing the counts to the DNA content of the sample. *c*, Fold increase refers to the ratio of kinase activity in tissues infected with virus and normalized to DNA content, compared with the corresponding normalized tissue in controls. Note that despite a 10-fold reduction in FFU, kinase activity at times is as high as in the tumours. As the infected wing cells *in ovo* have 'normal' morphology, they may not be able to replicate the virus at the same rate as transformed cells. This is supported by our preliminary data which indicate that transformed cells plated on normal extracellular matric flatten out and, while they contain appreciable kinase activity, virus replication is reduced considerably[45].

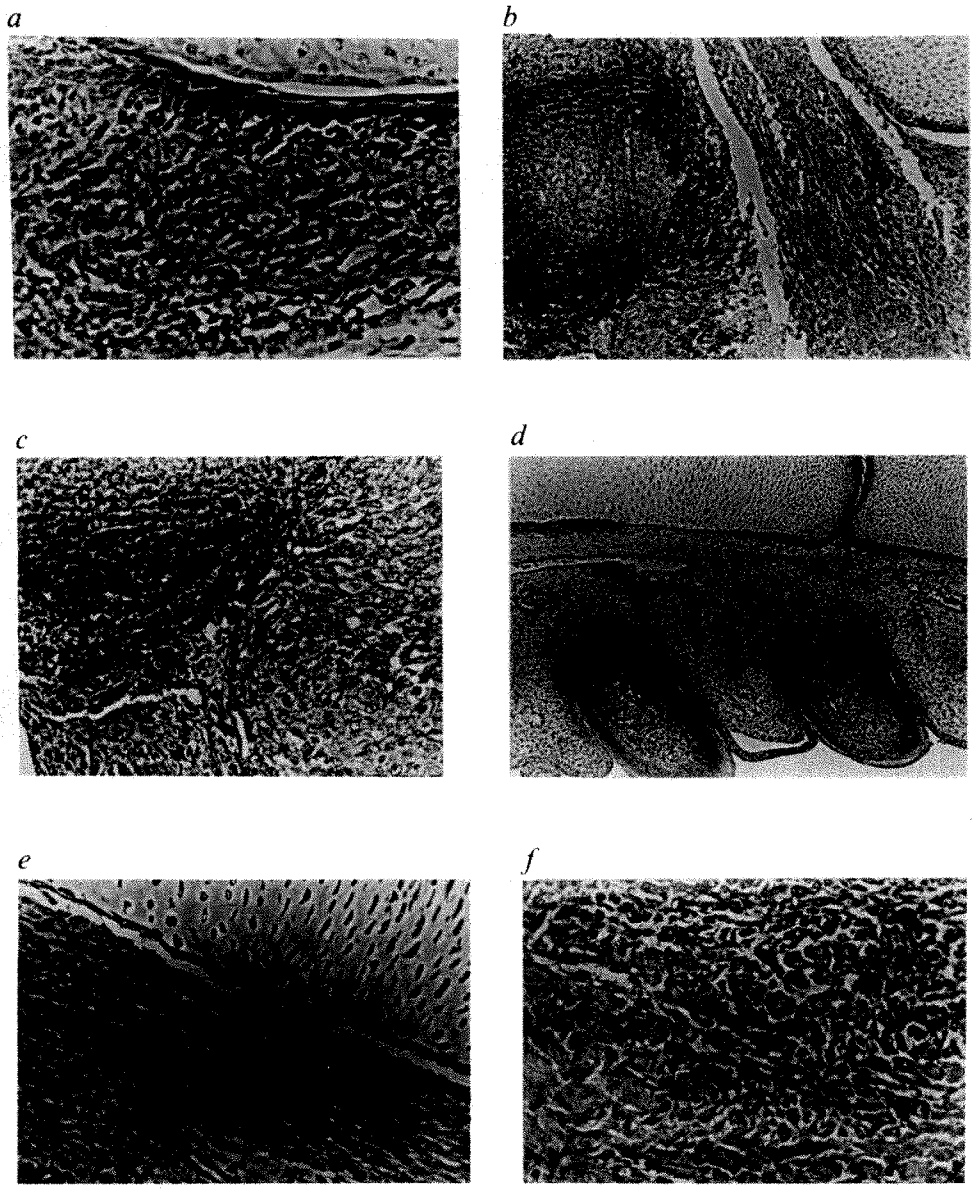

Fig. 1 Histology of inoculated limb buds and tumour tissue. *a–e*, Embryos were inoculated on day 4 as described in the text and were killed on the indicated day. The inoculated limb was removed and fixed in Bouins, embedded in paraffin and sectioned (5 μm). Sections were photographed after staining with haematoxylin and eosin using a Nikon diaphot microscope. *a*, Control limb inoculated with medium alone and killed on day 13. ×280. *b*, Limb inoculated with 10^5 FFU of SRD RSV and killed on day 13. ×105. Note the haemorrhagic lesion on the left. *c*, Same as *b*. Lesion is in the upper left quadrant. ×280. *d*, Limb inoculated with 10^5 FFU of SRD RSV and killed on day 12. ×70. No abnormal morphology was noted. *e*, Same as *d* showing the perichondrium and adjoining tissues. ×280. *f*, Tumour tissue from 10-day-old chicken, inoculated with 10^5 FFU of SRD RSV after hatching. Tumours first appeared on day 7. ×280.

Embryos which failed to show an increase in kinase activity also failed to show reverse transcriptase or focus-forming activity, and probably had not become infected, as discussed above.

We next addressed the following questions: (1) How do the cells from the limbs of infected 14-day-old embryos behave after being disrupted and placed in culture? (2) Are the cultured cells from the limb buds of 4-day-old embryos as susceptible to transformation and virus production as cells from older embryos? Using morphology and the rate of sugar uptake as two commonly measured criteria of transformation, we compared cultures prepared from the wing of inoculated embryos with either cultures derived from the wing of control embryos which were infected at the time of plating, or cultures derived from tumours generated in newly hatched chicks (Fig. 2). Cells were cultured in 25-mm multiwell plates at high density ($4–5 \times 10^5$ cells cm^{-2}) to discourage the horizontal spread of infectious virus. Chick cells cultured in these conditions grow slowly; the percentage of cells infected in the first 72 h is reduced by a factor of 5 or more compared with cultures infected at low density (data not shown). Despite high kinase activity which was elevated in the intact tissue and which remained high after disruption, cells infected *in ovo* appeared quite normal initially, by the criteria of both morphology and rate of sugar uptake. However, within 24 h the cultures became morphologically transformed (*en masse* rather than as foci) and the rate of sugar transport increased. This 'delayed' transformation is not due to the process of tissue disruption associated with the preparation of cultures, as cultures derived from tumour tissue or from fully transformed cultures retained a transformed morphology and high sugar uptake immediately after trypsinization and replating. On the other hand, cultures derived from normal embryos which were infected after plating (multiplicity of infection (MOI) = 0.2; approximately the same virus-to-cell ratio found in the infected limb tissue at the time of culturing) began to show foci of transformation and a stimulation of the rate of sugar transport only after an interval of 72 h.

Thus, embryonic cells infected *in ovo* retain their normal phenotype *in ovo*, as well as initially after plating, but the ability to display a transformed phenotype is rapidly acquired after the cells are placed in culture. It is possible that either the culture conditions are permissive for the expression of the transformed phenotype, or alternatively, these cells may experience an acceleration of the developmental programme which would normally lead to the tumour permissiveness observable in newly hatched chicks. The notion that the developmental programme of chick cells may accelerate in culture at high densities has been suggested by previous work in this laboratory[13].

To determine whether cells from the limb bud of day 4 embryos are as susceptible to transformation, and whether they

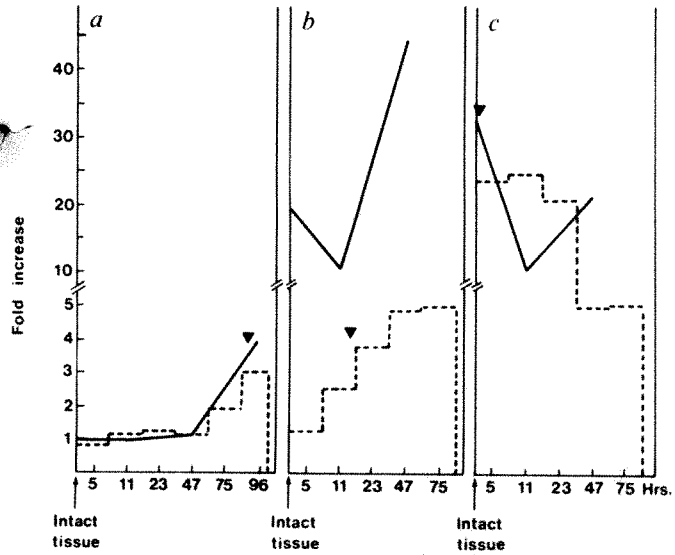

Fig. 2 Determination of transformation in cultures derived from the wing of control embryos infected at the time of plating (*a*), cultures prepared from the wing of inoculated embryos (*b*), and cultures derived from tumours generated in newly hatched chicks (*c*). Embryos were inoculated and killed as described in the text. The inoculated limb was removed and a portion of intact tissue was assayed for kinase activity as described in Table 1. The rest was digested for 45 min at 39 °C in a solution of medium F-10, 0.15% trypsin, 0.3% collagenase (type II) and 5% fetal calf serum. An aliquot was checked under a microscope to determine the extent of digestion and the incubation time was adjusted accordingly. After digestion, the cells were washed twice in medium 2-2-1, and plated at high density (4×10^5 cm^{-2}). At the times indicated, 2-deoxyglucose[46] (broken lines) and kinase[43] (solid lines) assays were performed. The assays for each time point were normalized to that of cultures of cells derived from uninfected embryos and are expressed as the fold increase relative to the control. ▼ Indicates the time of appearance of morphological transformation.

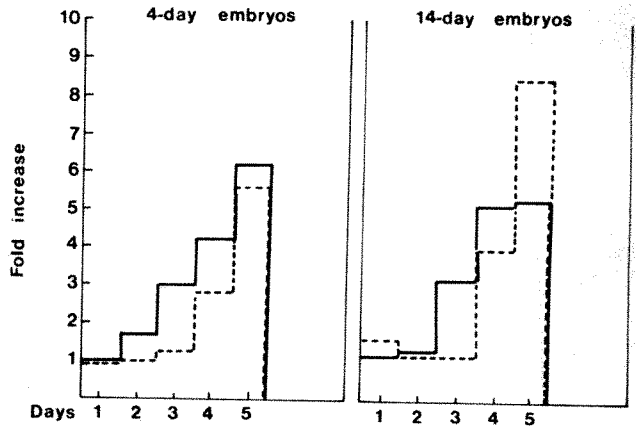

Fig. 3 Susceptibility to transformation of cells from limb buds of day 4 and day 14 embryos. The limb buds from several 4-day-old embryos were microdissected, pooled and dissociated as described in Fig. 2 legend. The lower limb of a 14-day-old embryo was prepared in the same fashion. Both were plated at low density (5×10^4 cells cm^{-2}), and half the plates from each group were infected with SRD RSV at a MOI of 2.0. 2-Deoxyglucose uptake (broken lines) and reverse transcriptase activity (solid lines), as well as morphology and cell number, were monitored daily. Each of the infected cultures was normalized to its uninfected counterparts and the result is expressed as the fold increase compared with the normal control.

produce progeny virus at the same rate, as cells derived from the limbs of day 14 embryos, limb bud tissues from the respective embryos were dissociated, plated at low density and infected with RSV at a high multiplicity of infection (MOI = 2). Cultures were subsequently screened for reverse transcriptase activity, sugar uptake and morphology. Predictably, the growth rates and subsequent morphologies of infected and uninfected cultures derived from day 4 embryos differed from those of their day 14 counterparts. However, the increase in sugar uptake and the production of viral particles (per cell) were comparable in both infected cultures (Fig. 3).

The infection and replication of RSV in certain avian embryo cell types in culture in the absence of transformation has been reported[14,15]. The infected limb cells in our experiments differ somewhat in that they express their transformed phenotype once placed in culture. This is not a selection phenomenon as we have shown recently that 90% of the isolated limb cells are positive for the presence of viral antigens before culturing (D.S.D., M. Gates and M.J.B., unpublished); and as shown in Fig. 2*b*, transformation in these cultures occurs *en masse* within 24 h. Dunkel and Groupe[16] found, several years ago, that embryonic day 3 limb buds infected *in vitro* and grafted onto the chorioallantoic membrane of 9-day-old eggs, show virus replication long before tumour foci appear. The eventual presence of tumours may be due to the disruptive nature of the grafting procedure, the altered developmental environment, or other differences in experimental conditions.

We are presently considering three general hypotheses which might explain the apparent inability of RSV to cause sarcomas in chick embryos. First, the intracellular concentration of viral kinase activity (or its localization) may be suboptimal. Second, a cellular component, required for tumorigenic expression, may be absent from the early embryo; this component might be a target for the viral kinase[17–20], for an 'additional' *src* gene-mediated activity[21–26], or a hormone, growth factor or endogenous promoter[27–30]. In addition to published data[24,25] for cases in which kinase activity alone does not appear to be sufficient for transformation in culture, there are recent data to indicate that some temperature-sensitive mutants of RSV have comparable kinase activity at both permissive and non-permissive temperatures (A. Stoker, P. Enrietto and J. Wyke, personal communication). This indicates the possible importance of other activities and/or domains in pp60^{src} for transformation[21–24]. Third, the early embryo may contain inhibitors for any of these necessary interactions[31,32]. We are presently determining whether or not known targets of pp60^{src} are phosphorylated in tyrosine *in ovo*.

We have been unable to determine whether embryos infected on day 4 of development will ultimately develop tumours. Due to the lethality of the virus around days 12–15, we have hatched only four of these embryos: none contained detectable tumours, although all four died within 4 days of hatching from as yet undetermined causes. Several examples exist both for sustained suppression of the neoplastic potential[31,33,34] and for temporary suppression related to the developmental stage of the animal[16,35–39], but obviously more embryos must be hatched to draw any firm conclusions.

How general are the implications of these findings for retroviral tumorigenicity in the embryo? Clearly, there is target specificity, and the age of the embryo and possibly route of injection are important factors. Smith and Iranyi[40] found evidence for target 'stem' cells in 12-day-old embryos when injected intravenously with myeloblastosis-associated virus (MAV)-2(0). These chickens developed suppression of bursal and thymic lymphoid cell development 2–3 weeks after hatching. A mutant of avian erythroblastosis virus appears to produce erythroblastosis in 12-day-old embryos efficiently, but it does not produce sarcomas in the embryos. Nevertheless, sarcomas are readily produced in 1-week-old chicks by the same mutant[41]. This latter finding supports our general conclusion that production of sarcomas in the embryo is either suppressed or requires additional factors not present in the embryo.

Note that most of the studies with chick embryos have been done using embryos over 10 days old and our studies were done

with 4-day-old embryos. It is possible that the susceptibility of the embryo to RSV tumorigenicity may increase as the embryo develops. It is also possible that if factors from transformed cells were present, one could induce tumours even in 4-day-old embryos. In preliminary studies we have failed to induce tumours with transformed cells. However, we could not ascertain whether or not the cells remained viable and will in future use cells such as quail that could be distinguished from chick cells.

It seems that while kinase activity of $pp60^{src}$ may be necessary for RSV-mediated transformation and tumorigenesis, there are one or several other developmentally related criteria which must be met before expression of the malignant phenotype is possible. The temporal sequence of the expression of viral and cellular factors may also be an important determinant. Infected cells, once placed in culture, overcome the *in ovo* restriction and become transformed rapidly. The mechanisms of both the restriction *in ovo* and transformation in culture are being investigated.

We thank Herman Oppermann, Bart Sefton and G. Steven Martin for gifts of antisera; Marguerite Vogt, Gernot Walter, Bart Sefton, Andrei Lazlo, Gordon Parry, John Wyke and Paula Enrietto for comments and critical review of the manuscript; Jill Hatier and Henry Nesis for technical assistance; Edward Alpen and Virginia Havens for providing the expertise of the Division's histology laboratory; and Harry Rubin for introducing us to the work of Duran-Reynals. § Department of Chemistry, University of California, San Diego, La Jolla, California 92096, USA

We report here significant primary sequence homology among the predicted translational products of three genes: *CDC4, CDC36* and *ets*. *CDC4* and *CDC36* are *Saccharomyces cerevisiae* cell division cycle genes, while *ets* is a transformation-specific sequence of avian erythroblastosis virus E26. The deduced primary structures of the three gene products were compared by computer to a large data base of known and predicted protein sequences[1]. The search revealed 22.0–25.5% identity over regions of 140–206 codons, respectively between the different pairwise combinations. For these particular sequences, these identity scores fall 3.4–4.0 standard deviations above the empirically-determined mean values of fortuitous similarity. *S. cerevisiae* calls require *CDC36* and *CDC4* in order to complete two early events in the cell cycle: execution of start (*CDC36*)[2] and spindle pole body separation (*CDC4*)[3]. In virus E26, the *ets* sequence is linked in frame with *Δgag* and myb^E in the tripartite structure 5′-*Δgag-myb*^{E}-*ets*-3′, comprising the E26 transforming oncogene[4,5]. The homologies described here suggest that the biochemical functions or regulation of the *CDC4, CDC36* and *ets* products may be related.

Figure 1 shows an alignment of the inferred amino acid sequences of the entire *CDC36* translational product (middle line) with homologous regions of the *CDC4* and *ets* products. The locations of these sequences in their respective genes are shown in Fig. 2. The lengths of the *CDC4, CDC36* and *ets* products are 779, 191 and 491 amino acid residues, respectively. Above the complete 191-residue *CDC36* sequence in Fig. 1 is the 149-residue C-terminal portion of the *CDC4* product. Below *CDC36* is a 206-residue region from the middle of the *ets* product (Fig. 2). The most striking similarities are observed near the *N*-terminus of the *CDC36* product. In this region, between *CDC36* Ala 8 and Ser 22, 6 out of 15 residues match among all three sequences, and 7 out of 15 match between two sequences. Another region of substantial similarity is the 10-residue region from *CDC36* Tyr 39 to Gln 48, in which the *CDC36* product

Table 1 Homology between pairwise combinations of *CDC4, CDC36* and *ets*

Gene pair	% Identity	Standard deviations above mean	Probability of fortuitous match
CDC4–CDC36	25.5	4.0	0.003%
CDC36–ets	22.0	4.0	0.003%
ets–CDC4	22.8	3.4	0.033%

% Identity refers to per cent of matching residues per sequence length. Standard deviations above mean refers to the number of standard deviations the alignment scores fall above a mean value of chance homology empirically determined by aligning a large number of scrambled sequences of identical composition and length (ref. 1 and see text). Probability of fortuitous match refers to expected per cent of random sequences with alignment scores greater than or equal to that of the genuine gene pair alignment, based on an empirical distribution of alignment scores of scrambled sequences (ref. 1 and see text).

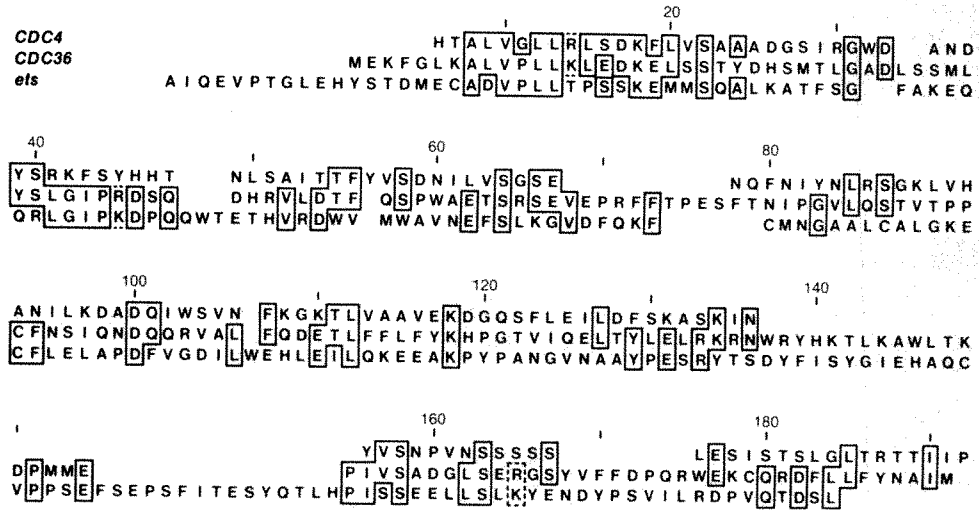

Fig. 1 Alignment of the predicted primary structures of the *CDC4*, *CDC36* and *ets* products. Amino acid identities are boxed; conservative changes are enclosed by dashed boxes. Sequence gaps necessary to obtain optimal alignment are represented by spaces. The coordinates refer to the *CDC36* residue number, with the initiating Met = 1. The *CDC36* product is aligned for maximal homology with the *CDC4* and *ets* products. This alignment does not give the maximal homology between *CDC4* and *ets*. Single-letter abbreviations for the amino acid residues are as follows: A, alanine; C, cysteine; D, aspartic acid; E, glutamic acid; F, phenylalanine; G, glycine; H, histidine; I, isoleucine; K, lysine; L, leucine; M, methionine; N, asparagine; P, proline; Q, glutamine; R, arginine; S, serine; T, threonine; V, valine; W, tryptophan; Y, tyrosine.

Methods: *CDC36* and *CDC4* were isolated on recombinant plasmids by transformational complementation (ref. 18 and unpublished data). Each was shown to represent the authentic *CDC36* and *CDC4* genes by their ability to recombine at their respective genomic loci (ref. 18 and unpublished data). The *CDC36* and *CDC4* genes were localized by subcloning, RNA blot analysis and R-loop mapping (ref. 18 and unpublished data). *CDC4* was sequenced by chemical degradation methods[19] and found to contain a large open reading frame of 779 codons. The 149 C-terminal residues of the *CDC4* predicted translational product are shown. Sequencing of *CDC36* by the m13-dideoxy method[20] revealed an open reading frame of 191 codons within the 615-base pair transcribed sequence. The complete *CDC36* deduced translational product is shown. A clone prepared from cDNA transcribed *in vitro* from E26 genomic RNA was sequenced by the m13-dideoxy method[20] and found to contain an *E26 t*ransformation-*s*pecific (*ets*) sequence flanked by *myb*^{E} (an internal 0.8-kb subset of the 1.2-kb AMV-related sequence, *myb*^{A}) and an *env*-related sequence[4]. *ets* encodes the C-terminal 491 amino acid residues of p135 (ref. 4 and Fig. 2). 206 residues of the *ets* predicted translational product are shown.

matches either the *CDC4* or *ets* products at 8 of the 10 positions. We view these similarities as strong evidence that these gene products are related. Overall, the homology between the different pairwise combinations ranges from 22.0 to 25.5%. These scores were compared with the results of a 'jumble test', in which sets of scrambled sequences whose compositions and lengths are identical to those of the two sequences under study (that is, between 149, 191 and 206 codons of *CDC4*, *CDC36* and *ets*, respectively; see Fig. 2) are subjected to the same alignment and scoring procedure used for the authentic alignment[1]. The homology values of the genuine sequences were found to lie 3.4–4.0 standard deviations above the mean values of the randomized sequences, indicating a low probability that the similarities detected are fortuitous (Table 1). We cannot rigorously exclude the possibility that any of the similarities detected here are the results of convergent, rather than divergent, evolution. However, since a particular protein structure can be obtained from many different amino acid sequences, sequence convergence extending over significant lengths (for example, >20 residues) is highly unlikely. Additionally, the requirement for both the *CDC4* and *CDC36* products in the G_1 phase in the same organism (see below) suggests an ancestral relationship for these two genes.

CDC4 and *CDC36* both define early events in the cell cycle of the budding yeast *S. cerevisiae* (see ref. 6 for review). Cells defective in *CDC36* arrest division at start, a point in the late G_1 phase of the cell cycle[2,7]. Start appears to be the cell cycle stage at which cell division is normally controlled, as wild-type cells deprived of essential nutrients or responding to mating pheromone also arrest at start[7]. Cells arrested at this stage are unbudded and have not yet undergone duplication of the spindle pole body, which serves as the microtubule-organizing structure[3]. The next defined step in the mitotic cycle requires *CDC4*. Cells arrested by the *cdc4* defect also fail to initiate DNA synthesis[8] and have duplicated but unseparated spindle pole bodies[3]. Completion of the *cdc4*-sensitive step results in separation of the duplicated spindle pole bodies, which migrate to opposite sides of the nucleus to become the poles of the mitotic spindle[3]. Although arrest by *cdc4* is morphologically advanced with respect to start, cells at both stages remain in G_1. Moreover, both of these arrests share the properties that (1) entry into the S phase requires additional protein synthesis[9] and (2) the cells may enter directly into meiosis without completing a mitotic cycle if transferred to the appropriate medium[10]. By contrast, *CDC7* defines a later period of the G_1 phase which lacks these properties. Therefore, it is not unreasonable to suppose that the structural feature shared by the products of *CDC4* and *CDC36* is essential to their function or regulation in a segment of G_1.

ets is a genomic sequence of the avian erythroblastosis virus E26[4,5]. E26 is related to avian myeloblastosis virus (AMV) in that both viruses are replication-defective, contain a *myb* (or *amv*) sequence, and cause acute myeloblastic leukaemia yet do not transform chicken fibroblasts in culture[11,12]. However, the predominant disease caused by E26 is erythroblastosis, whereas AMV causes myeloblastosis exclusively[13,14]. The E26 oncogene is a tripartite hybrid composed of the in-frame fusions 5′-Δ*gag*-*myb*^{E}-*ets*-3′ (refs 4,5). The Δ*gag*, *myb*^{E} and *ets* sequences comprise 0.8, 0.8 and 1.5 kilobases (kb), respectively, of the hybrid gene[4]. This oncogene codes for a putative transforming protein of 135,000 molecular weight, termed p135 (ref. 12), of which *ets* encodes the C-terminal 491 residues[4] (Fig. 2). DNA hybridization experiments revealed the existence of cellular proto-*ets* sequences, which are unlinked to proto-*myb*[4,5].

The biological functions of the *CDC4*, *CDC36* and *ets* products remain unknown. The product of another yeast start gene, *CDC28*, is homologous to the products of the *src* gene family, many of which have been shown to encode protein kinases[15]. In view of these results it is conceivable that the products of retroviral transforming genes share functional domains with proteins that control cell division. Other authors have reported

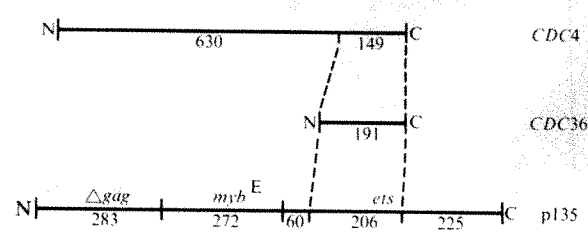

Fig. 2 The locations of the sequences compared in Fig. 1 relative to the complete gene products. Numbers below each line indicate the residue length of that section. Dashed lines enclose homologous sequences presented in Fig. 1. N and C refer to the amino and carboxy termini, respectively. Drawn approximately to scale.

significant homology between other yeast sequences and the vertebrate oncogenic sequence *ras*[16,17]. Our findings extend these observations and support the notion that the mechanisms controlling cell division in yeast and cellular proliferation in vertebrates may be related.

A novel protease from yeast with specificity towards paired basic residues

Kensaku Mizuno & Hisayuki Matsuo

Department of Biochemistry, Miyazaki Medical College, Kiyotake, Miyazaki 889-16, Japan

Paired basic residues have been observed as sites of proteolytic processing of prohormones in a wide range of eukaryotic species[1–3]. This strongly suggests that proteases exhibiting specificity towards paired basic residues may be involved in prohormone processing, but candidate enzymes have not so far been identified. Yeast *Saccharomyces cerevisiae* α-cells synthesize and secrete α-mating factor, a peptide of 13 amino acids[4,5], the processing of which from a larger precursor involves cleavage at paired basic residues (-Lys-Arg-)[3,6]. We have therefore used them as a simple model system for the study of prohormone processing and report here the identification, in cell lysates, of a novel protease which specifically recognizes and cleaves the peptide bonds between consecutive basic residues. The purified enzyme, which we have called propheromone-convertase Y, has a molecular weight (MW) of around 43,000. It cleaves various peptide substrates at paired basic residues, but not at single basic residues, implying it is distinct from trypsin-like proteases. Its unique substrate specificity suggests the enzyme may be involved in propheromone processing *in vivo*.

Proteolytic activity specific to consecutive basic residues was monitored in lysates of yeast *S. cerevisiae* α-cells by measuring in a sensitive radioimmunoassay[7] the amount of Tyr-Gly-Gly-Phe-Leu-Arg ([Leu]enkephalin-Arg) released from the synthetic C-terminally α-amidated peptide Tyr-Gly-Gly-Phe-Leu-Arg-Arg-Phe-Ala-NH_2 ([Leu]enkephalin-Arg-Arg-Phe-Ala-NH_2). Since the antiserum used in the radioimmunoassay was directed against the C-terminus of [Leu]enkephalin-Arg, neither the substrate nor its fragmented peptides other than [Leu]enkephalin-Arg showed immunoreactivity[7].

The soluble fraction of the yeast lysates was chromatographed on a column of DEAE-Sephadex A-25. The enzyme activity

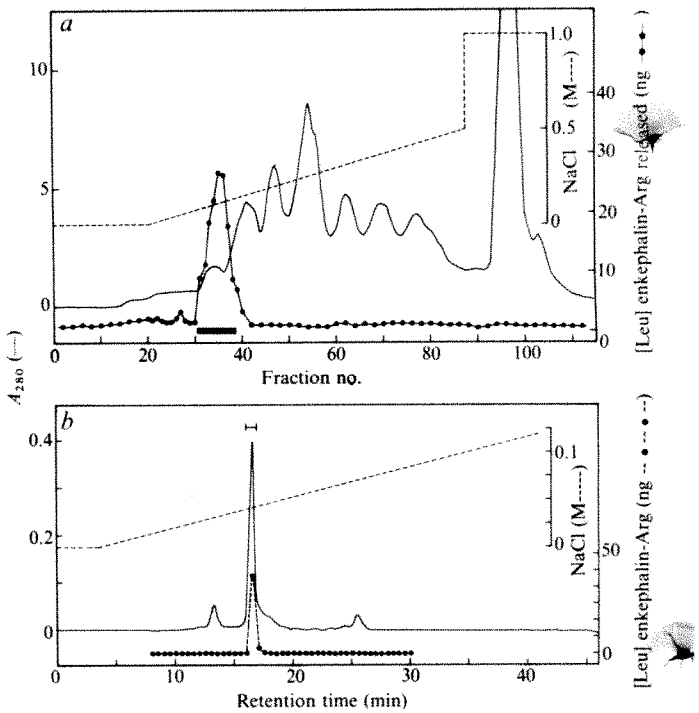

Fig. 1 Purification of the enzyme from lysates of yeast α-cells. *a*, DEAE-Sephadex A-25 chromatography of crude extracts of yeast α-cells. *b*, Final purification of the enzyme by second FPLC on a Mono Q anion-exchange column.
Methods: Haploid strain *S. cerevisiae* X-2180 1B (α-mating type cell) was supplied by Dr T. Tanaka, Suntory Ltd. For purification of the enzyme, cells were grown aerobically at 28 °C for 50 h in 6 l of YM-medium, containing 0.3% yeast extract, 0.3% malt extract, 0.5% polypeptone (pancreatic digest of casein) and 1% glucose. Cells (wet weight 45 g) were lysed by incubation with Zymolyase-60,000 (Seikagaku Kogyo) at 35 °C for 4 h (ref. 17), and homogenized with a Polytron homogenizer. After centrifugation at 30,000*g* for 30 min, ammonium sulphate was directly added to the supernatant to a final concentration of 90% saturation and the resulting precipitate was resuspended in 10 mM Tris-HCl buffer, *p*H 8.0, and dialysed against the same buffer. The dialysate was applied to a column of DEAE-Sephadex A-25 (3 × 30 cm), equilibrated with the same buffer. The column was washed with 10 mM Tris-HCl buffer (*p*H 8.0) and then eluted with a 1-l linear gradient from 0 to 0.5 M NaCl in the same buffer. Fractions of 15 ml were collected at a flow rate of 30 ml h^{-1}. Enzyme activity was assayed by using the synthetic enkephalin-containing peptide, Tyr-Gly-Gly-Phe-Leu-Arg-Arg-Phe-Ala-NH_2, as a substrate. Aliquots (20 μl) from each fraction were incubated at 37 °C for 2 h with 0.1 nmol of the substrate in 100 μl of 0.1 M ammonium acetate buffer (*p*H 5.5) containing 1 mM EDTA and 1 mM dithiothreitol. After stopping the reaction by 10 min of boiling, the amount of [Leu]enkephalin-Arg generated was measured by radioimmunoassay using an antiserum directed against the C-terminus of [Leu]enkephalin-Arg as reported previously[7] (–●–●–●–). The enzyme fractions (marked with bar) obtained from DEAE-Sephadex A-25 chromatography were pooled and concentrated by 90% ammonium sulphate precipitation. The precipitate was dissolved in 8 ml of 0.1 M ammonium acetate buffer (*p*H 5.5) containing 1 mM EDTA and applied to a column (3 × 140 cm) of Sephacryl S-300 (superfine), equilibrated with the same buffer. The enzyme activity was assayed as described above and the active fractions eluted in 660–740 ml were pooled and dialysed against 5 mM Tris-HCl buffer, *p*H 8.0. The dialysate was subjected to FPLC using an anion-exchange Mono Q column (0.5 × 5 cm, Pharmacia). Elution was carried out with a linear gradient from 0 to 0.125 M NaCl in 5 mM Tris-HCl buffer (*p*H 8.0). The main active fractions were collected and diluted with 5 vols of distilled water and rechromatographed in the same conditions as described above. The effluent was monitored by absorbance at 280 nm. Fractions of 0.5 ml were collected at a flow rate of 1.0 ml min^{-1}. Aliquots (0.2 μl) of each fraction were assayed by 2 h of incubation with 0.1 nmol of substrate ([Leu]enkephalin-Arg-Arg-Phe-Ala-NH_2) in 100 μl of 0.1 M Tris-HCl buffer, *p*H 7.4 (--●--●--●--). The active fraction (marked with bar) was collected and used as the purified enzyme.

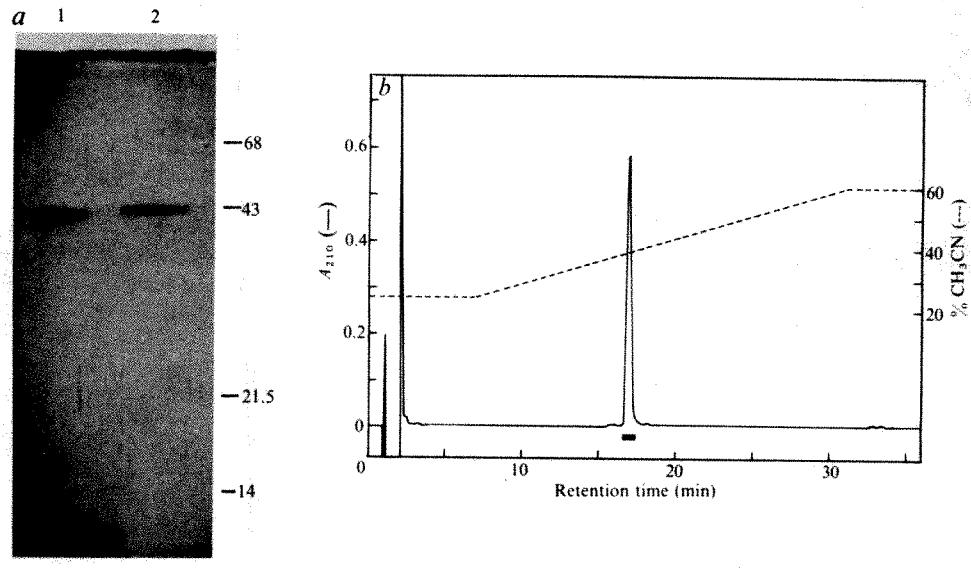

Fig. 2 *a*, SDS-polycrylamide gel electrophoresis analyses of the purified enzyme in the absence (lane 1) or the presence (lane 2) of the reducing reagent. The purified enzyme obtained from Mono Q chromatography in Fig. 1*b* was loaded on 2.0-mm slab gel using a 15% polyacrylamide gel and a discontinuous buffer system[18]. Proteins were analysed using silver stain method (Bio Rad). Lane 1, 100 ng of the unreduced enzyme. Lane 2, 100 ng of the reduced enzyme, treated with 5% 2-mercaptoethanol at 100 °C for 3 min before application to the gel. The R_F positions of molecular weight standards (bovine serum albumin, MW 68,000; ovalbumin, MW 43,000; soybean trypsin inhibitor, MW 21,500; cytochrome *c*, MW 14,000) are indicated at the right. *b*, Reverse-phase HPLC analysis of the purified enzyme. One eighth of the purified enzyme obtained from Mono Q chromatography in Fig. 1*b* was analysed by reverse-phase HPLC on a column (0.4 × 25 cm) of TSK LS-410 ODS-SIL (Toyosoda). Elution was carried out with a linear gradient (24 min) of CG_3CN concentration from 24 to 60% in 0.1% trifluoroacetate solution. Flow rate was 2 ml min^{-1}. The effluent was monitored by absorbance at 210 nm.

producing [Leu]enkephalin-Arg from the substrate was found in fractions 31–38, which were well separated from other proteins (Fig. 1*a*). The active portion was further purified by gel-filtration on a Sephacryl S-300 column, followed by ion-exchange fast protein liquid chromatography (FPLC) on a Mono Q column and finally a second FPLC on the same column (Fig. 1*b*), which resolved the enzyme activity as a single protein peak. The purified enzyme was verified to be homogeneous on SDS-polyacrylamide gel electrophoresis both in the absence and in the presence of 5% 2-mercaptoethanol (Fig. 2*a*), from which we conclude it consists of a single polypeptide chain with a MW of about 43,000, and by analysis on reverse-phase HPLC (Fig. 2*b*). Although HPLC resulted in a marked decrease of enzyme activity, an appreciable amount of enzyme activity (indicated by bar) was detected only at the position of a single symmetrical protein peak. Starting with 45 g of yeast α-cells, the procedure yielded about 0.1 mg of purified enzyme.

HPLC of reaction products from [Leu]enkephalin-Arg-Arg-Phe-Ala-NH_2 after 2 h of incubation with the purified enzyme at 37 °C resolved three peptide peaks (1–3), which, on the basis of amino acid analyses and comparison of retention time on HPLC with authentic peptides, have been identified as Arg-Phe-Ala-NH_2 (peak 1), Tyr-Gly-Gly-Phe-Leu-Arg (peak 2) and the starting Tyr-Gly-Gly-Phe-Leu-Arg-Arg-Phe-Ala-NH_2 (peak 3). The stoichiometric recovery of reaction products (peak 1, 3.7 nmol; peak 2, 3.6 nmol) suggests that the enzyme exclusively hydrolyses the Arg-Arg bond of the substrate. To characterize the substrate specificity of the enzyme, various peptides were incubated with it and the resultant mixtures analysed on reverse-phase HPLC. We found the enzyme converts [Leu]enkephalin-Lys-Arg-Phe-Ala-NH_2 to [Leu]enkephalin-Lys and Arg-Phe-Ala-NH_2, and [Leu]enkephalin-Arg-Lys-Tyr-Pro-NH_2 to [Leu]enkephalin-Arg and Lys-Tyr-Pro-NH_2, by cleaving the Lys-Arg bond and the Arg-Lys bond respectively (Fig. 3*b*, *c*). It catalysed the hydrolysis of X—Y peptide bonds (X, Y: basic residues) of various peptides examined, but peptides containing a single basic residue in the molecule, such as [Leu]enkephalin-Arg-NH_2, [Met]enkephalin-Arg-Phe-NH_2 (Fig. 3*d*) and [Met]enkephalin-Arg-Gly-Leu, were resistant to the action of the enzyme. Furthermore, typical substrates for trypsin, such as tosyl-L-arginine methyl ester (Tos-Arg-OMe; concentration 1.04 mM)[8] and benzoyl-L-arginine 4-methyl-coumaryl-7-amide (Bz-Arg-MCA; 50 μM)[9], were not affected by the enzyme. When rimorphin, which has both consecutive basic residues (-Arg-Arg-) and a solitary basic residue (-Lys-) in the molecule[10] was examined as a substrate, only the Arg-Arg peptide bond was split by the enzyme (Fig. 3*e*, Table 1). These results strongly suggest that the enzyme is an endopeptidase, which specifically attacks the peptide bond between consecutive basic residues. Thus its action is distinct from that of trypsin.

The kinetic constants for [Leu]enkephalin-Arg-Arg-Phe-Ala-NH_2 and [Leu]enkephalin-Lys-Arg-Phe-Ala-NH_2 were determined from Lineweaver–Burk plots with substrate concentrations varying from 0.2 to 1.6 mM. Each substrate was incubated with the enzyme ($[E_0] = 1.09 \times 10^{-8}$ M) for 10 min at 37 °C in 100 μl of Tris-HCl buffer, *p*H 7.4. The reaction was stopped by the addition of 100 μl of 1 M HCl and the amounts of Arg-Phe-Ala-NH_2 released were analysed by amino acid analyses after separating the peptides on reverse-phase HPLC. The apparent K_m and k_{cat} values thus determined were 0.588 mM and 6.82 s^{-1} for [Leu]enkephalin-Arg-Arg-Phe-Ala-NH_2 and 0.329 mM and 2.52 s^{-1} for [Leu]enkephalin-Lys-Arg-Phe-Ala-NH_2 respectively.

The effects of *p*H and various inhibitors on the activity of the enzyme were examined, using [Leu]enkephalin-Arg-Arg-Phe-Ala-NH_2 as a substrate. The optimal *p*H for enzyme activity was around 7.5, with considerable activity being observed in the wide *p*H range 5–10. The enzyme was completely inhibited by serine-protease inhibitors such as phenylmethylsulphonyl fluoride and diisopropyl fluorophosphate at concentrations of

Table 1 Substrate specificity of the enzyme, with cleavage sites indicated by arrows

Peptides hydrolysed by the enzyme:

Tyr-Gly-Gly-Phe-Leu-Arg↓Arg-Phe-Ala-NH_2

Tyr-Gly-Gly-Phe-Leu-Lys↓Arg-Phe-Ala-NH_2

Tyr-Gly-Gly-Phe-Leu-Arg↓Lys-Tyr-Pro-NH_2 (β-neoendorphin-NH_2)

Tyr-Gly-Gly-Phe-Leu-Arg↓Arg-Ile (PH-8P)

Asp-Tyr-Gln-Lys↓Arg-Tyr-Gly-Gly-Phe-Leu

Tyr-Gly-Gly-Phe-Leu-Arg↓Arg-Gln-Phe-Lys-Val-Val-Thr (rimorphin)

Peptides not hydrolysed by the enzyme:
Tyr-Gly-Gly-Phe-Leu-Arg, Tyr-Gly-Gly-Phe-Leu-Lys,
Tyr-Gly-Gly-Phe-Leu-Arg-NH_2, Tyr-Gly-Gly-Phe-Met-Arg-Phe,
Tyr-Gly-Gly-Phe-Met-Arg-Phe-NH_2, Tyr-Gly-Gly-Phe-Met-Arg-Gly-Leu,
Tos-Arg-OMe(TAME), Bz-Arg-MCA

Each peptide (~4 nmol) was incubated with the enzyme in the same conditions as described in Fig. 3 legend. Reaction mixtures were analysed on reverse-phase HPLC and the resultant peptide peaks identified by amino acid analyses. Basic amino acid residues are underlined.

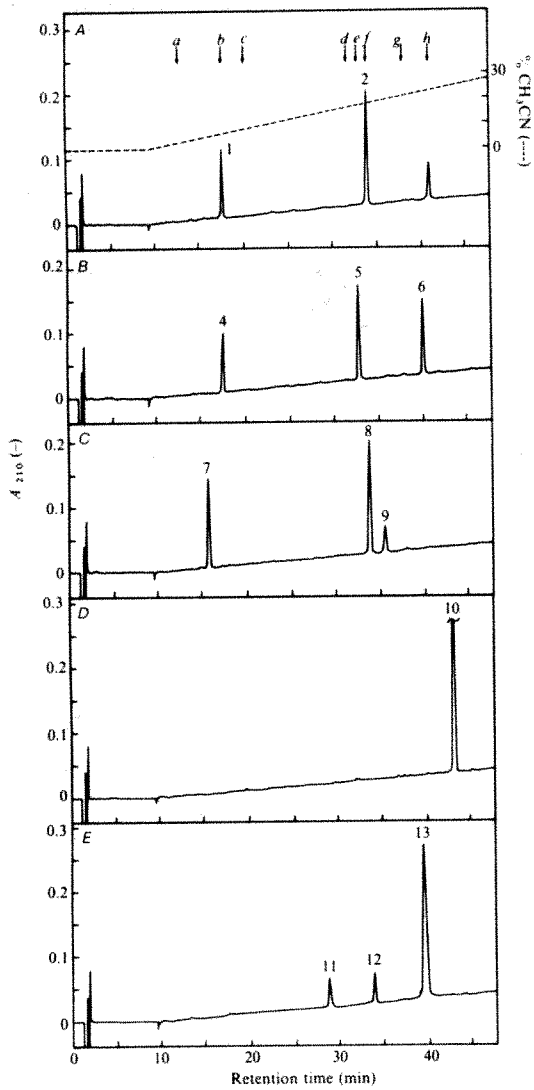

Fig. 3 HPLC patterns of the reaction products from [Leu]enkephalin-Arg-Arg-Phe-Ala-NH_2 (*A*), [Leu]enkephalin-Lys-Arg-Phe-Ala-NH_2 (*B*), [Leu]enkephalin-Arg-Lys-Tyr-Pro-NH_2 (*C*), [Met]enkephalin-Arg-Phe-NH_2 (*D*) and rimorphin (*E*), obtained by incubation with the purified enzyme. Approximately 4 nmol of the substrate peptides were incubated at 37 °C for 2 h with 0.1 μg of the purified enzyme in 100 μl of Tris-HCl buffer, *p*H 7.4. After the reaction was stopped by the addition of 20 μl of 1 M HCl, the solution was directly applied to a column of TSK LS-410 ODS-SIL (0.4 × 25 cm). Elution was carried out with a linear gradient (80 min) of CH_3CN concentration from 0 to 60% in 0.1% trifluoroacetate solution. Flow rate was 2 ml min^{-1}. The effluent was monitored by absorbance at 210 nm. The respective peptide peaks were collected, hydrolysed with 6 M HCl at 110 °C for 22 h, and analysed on an amino acid analyser (Hitachi 835). Based on amino acid composition and comparison of retention time with authentic peptides, the peptide peaks were identified as follows (yields of the peptides are designated in parentheses). *A*: 1, Arg-Phe-Ala-NH_2 (3.7 nmol); 2, Tyr-Gly-Gly-Phe-Leu-Arg (3.6 nmol); 3, Tyr-Gly-Gly-Phe-Leu-Arg-Arg-Phe-Ala-NH_2 (0.7 nmol). *B*: 4, Arg-Phe-Ala-NH_2 (3.1 nmol); 5, Tyr-Gly-Gly-Phe-Leu-Lys (2.9 nmol); 6, Tyr-Gly-Gly-Phe-Leu-Lys-Arg-Phe-Ala-NH_2 (1.4 nmol). *C*: 7, Lys-Tyr-Pro-NH_2 (3.5 nmol); 8, Tyr-Gly-Gly-Phe-Leu-Arg (3.4 nmol); 9, Tyr-Gly-Gly-Phe-Leu-Arg-Lys-Tyr-Pro-NH_2 (0.3 nmol). *D*: 10, Tyr-Gly-Gly-Phe-Met-Arg-Phe-NH_2 (3.9 nmol). *E*: 11, Arg-Gln-Phe-Lys-Val-Val-Thr (1.0 nmol); 12, Tyr-Gly-Gly-Phe-Leu-Arg (0.98 nmol); 13, Tyr-Gly-Gly-Phe-Leu-Arg-Arg-Gln-Phe-Lys-Val-Val-Thr (2.7 nmol). The elution positions of authentic peptides are indicated by arrows: *a*, Phe-Ala-NH_2; *b*, Arg-Phe-Ala-NH_2; *c*, Arg-Arg-Phe-Ala-NH_2; *d*, Tyr-Gly-Gly-Phe-Leu-Lys-Arg; *e*, Tyr-Gly-Gly-Phe-Leu-Lys; *f*, Tyr-Gly-Gly-Phe-Leu-Arg; *g*, Tyr-Gly-Gly-Phe-Leu; *h*, Tyr-Gly-Gly-Phe-Leu-Arg-Arg-Phe-Ala-NH_2.

2×10^{-4} M. Thiol-protease inhibitors, such as monoiodoacetate, and *p*-chloromercuribenzoic acid and metal chelators, such as EDTA and 1,10-phenanthroline at 10^{-3} M, had no effect on enzyme activity. The enzyme can therefore be classified as a serine protease. However, its resistance to the general trypsin inhibitors tosyl-L-lysine chloromethyl ketone (10^{-3} M) and leupeptin (10^{-4} M) indicate that it is distinct from pancreatic trypsin and other related proteases. The recognition mechanism of paired basic residues exhibited by the enzyme was very different from that exhibited by trypsin.

The enzyme described here appears to be a unique and novel endoprotease, showing a substrate specificity and an inhibitor spectrum different from other putative prohormone-processing enzymes[11–16]. The strict substrate specificity of the enzyme towards paired basic residues indicates that the enzyme may be physiologically involved in the essential function of propheromone processing. Further investigation is necessary to demonstrate whether the cleavage at the peptide bond between the paired basic residues generally occurs as the initial proteolytic event in prohormone-processing in tissues.

We thank Dr T. Tanaka for supplying yeast α-cells, Dr K. Kangawa for valuable comments, and Mrs M. Irikura and T. Hatoh for technical assistance. The investigation was supported in part by research grant from the Ministry of Education, Science and Culture of Japan.

Lithium reversibly inhibits microtubule-based motility in sperm flagella

Barbara H. Gibbons & I. R. Gibbons

Pacific Biomedical Research Center, University of Hawaii, Honolulu, Hawaii 96822, USA

The sliding-tubule hypothesis of flagellar movement has strong experimental support[1], but our present knowledge of the mechanism by which this sliding is coordinated and converted into flagellar oscillation and bend propagation is quite limited. Among the few facts known are: (1) calcium has a role in regulating the asymmetry of flagellar waveform[2,3], (2) the initiation or activation of motility in spermatozoa from several species involves a cyclic AMP-dependent phosphorylation reaction[4–7], and (3) the conversion of tubule sliding to bending does not require the radial spokes or central tubules[8,9]. Inhibitors are valuable tools for investigating mechanisms involved in cellular function, and we report here that Li^+ in low concentrations reversibly inhibits the microtubule-based movement of reactivated sea urchin sperm flagella. The evidence indicates that the action of Li^+ is directed primarily towards one or more regulatory sites through which Ca^{2+} modulates the asymmetry of flagellar waveform, rather than towards dynein ATPase

itself. Lithium also appears to inhibit the sperm adenylate cyclase, but this action does not seem to be relevant to its inhibition of normal motility. Our findings indicate the need for considerable caution when using ATP analogues supplied as the Li^+ salt.

Sperm from the sea urchin, *Tripneustes gratilla*, were demembranated in the presence of Ca^{2+} (refs 2, 3) and reactivated at 22–23 °C (Fig. 1). In these conditions the waveforms of the sperm flagella are nearly symmetrical when they are reactivated with Mg-ATP^{2-} at low ($<10^{-6}$ M) Ca^{2+} concentration, becoming asymmetrical only at higher Ca^{2+} concentrations. In the reactivating solution used here, the Mg-ATP^{2-} concentration is 0.5 mM, free Mg^{2+} is 0.1 mM (ref. 10), and the sperm flagella beat at a frequency of 26.0 ± 1.1 Hz (average of six preparations, 69 sperm). Addition of 6–8 mM Li acetate caused abrupt and complete cessation of movement, with the majority of the flagella assuming a straight or almost straight configuration. Dilution of these immobilized sperm 100-fold into fresh reactivating solution without Li^+ immediately restored movement in all of the sperm, with the flagellar beat frequencies and waveforms being indistinguishable from those in the starting preparation. A few experiments were also performed with sperm prepared by demembranation in a solution containing 2 mM EGTA and no added Ca^{2+} (refs 2, 3). When these sperm were reactivated with 0.5 mM Mg-ATP^{2-}, their flagellar waveforms were markedly asymmetrical, even in reactivating solution with a low concentration of Ca^{2+} ($<10^{-8}$ M), and addition of 0.1 mM Ca^{2+} induced quiescence, with the sperm flagella assuming a stationary, sharply bent cane-shape[3]. Addition of Li^+ to such preparations at low Ca^{2+} concentration inhibits the motility similarly to that of sperm demembranated in the presence of Ca^{2+}, except that instead of being nearly straight, the immobilized flagella are bent into cane-shapes resembling the quiescent form produced by Ca^{2+} (refs 3, 11). Addition of 5 mM LiCl to live sperm swimming in seawater had no noticeable effect on motility parameters, but 55 mM LiCl increased waveform asymmetry significantly and decreased longevity.

The standard reactivating solution for this work contained less Mg^{2+} than in our earlier studies because free Mg^{2+} seems to compete with Li^+. Thus, while 6 mM Li^+ was sufficient to inhibit the sperm in the presence of 0.1 mM free Mg^{2+}, as much as 20 mM Li^+ was needed at 3 mM free Mg^{2+}. Moreover, addition of either 3 mM Mg^{2+} or 6 mM Ca^{2+}, to sperm inhibited initially by 6 mM Li^+ at 0.1 mM free Mg^{2+}, induced the resumption of motility in >90% of the sperm.

Li^+ at concentrations lower than are needed to completely stop the reactivated movement cause a decrease in flagellar beat frequency (Fig. 1). As the Li^+ concentration is increased, a substantial increase in the asymmetry of the bending waves is observed, and a progressively greater percentage of the sperm become non-motile. Although it becomes difficult to strobe the highly asymmetric sperm flagella above 4 mM Li^+, it appears that none beat at frequencies lower than ~17 Hz, corresponding to 65% of the uninhibited value.

The demembranated sperm can be desensitized to the inhibitory effects of Li^+ by brief digestion with trypsin at a trypsin/sperm protein ratio of ~1:10. Addition of 0.2 μg trypsin ml^{-1} to the reactivating solution containing sperm immobilized with 6–24 mM Li^+ induced a gradual resumption of flagellar beating until after 2–3 min over 90% of the sperm were swimming vigorously. Their waveforms were symmetric and resembled those in undigested control preparations without Li^+, but their beat frequency was diminished to an extent that depended on the Li^+ concentration (Fig. 2). The rate at which motility was restored by trypsin is approximately the same as the rate at which trypsin eliminated the Ca^{2+}-induced asymmetry of flagellar waveform in a parallel observation dish containing 6 mM Ca^{2+} and no Li^+ (ref. 12).

Li^+ is known to inhibit many adenylate cyclases[13,14], and our preliminary experiments have suggested that the cyclase in these sperm is also blocked by Li^+. In view of this fact, we investigated the effect of cyclic AMP on Li^+ inhibition and found that addition of 10 μM cyclic AMP to preparations inhibited by

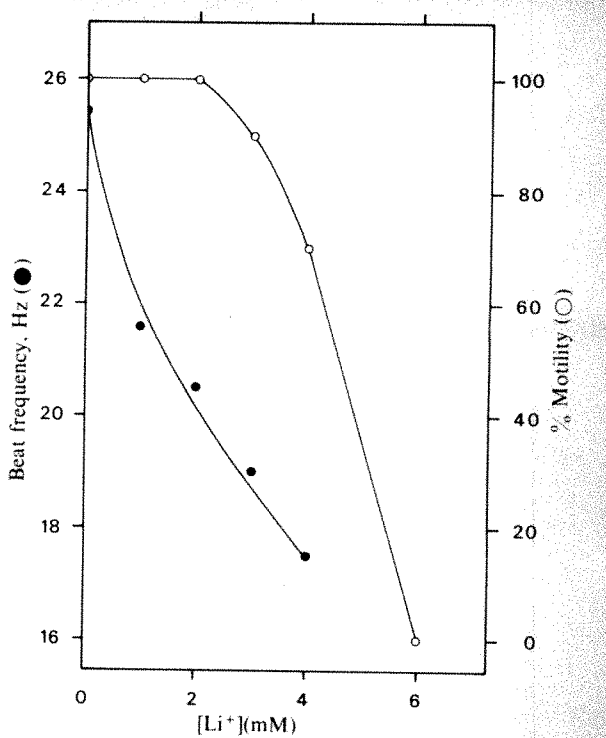

Fig. 1 Decrease in beat frequency (●) and percentage of motile sperm (○) as a function of Li^+ concentration. Sperm were demembranated in a solution containing 0.04% Triton X-100, 4 mM $CaCl_2$, 1 mM dithiothreitol (DTT), 0.1 mM EGTA and 10 mM Tris-HCl, *p*H 8.0 (potentially symmetrical conditions)[3] and reactivated at 21.5 °C in a solution containing 0.2 M K acetate, 0.1 mM EGTA, 1 mM DTT, 2% polyethylene glycol (molecular weight 20,000), 0.6 mM $MgSO_4$, 1.0 mM ATP, 10 mM Tris-HCl, *p*H 8.3 (ref. 22), and the indicated concentration of Li acetate.

6 mM Li^+ caused a partial reversal of the inhibition. In most of the 21 preparations observed, 30–70% of the sperm flagella resumed beating with highly asymmetric waveforms, although in a few it was as low as 15% or as high as 90%. The average frequency in these conditions was 18.4 ± 1.4 Hz (4 preparations, 54 sperm), significantly lower than that of sperm flagella desensitized by trypsin digestion, at this Li^+ concentration (Fig. 2). It is unclear what factors influence the degree of reversal obtained with cyclic AMP. Increasing the cyclic AMP concentration to 100 μM had no further effect. However, increasing the Li^+ concentration to 16 mM always resulted in a substantial decrease in the extent of reversal obtained with cyclic AMP, although it did not affect the extent of reversal obtained by dilution; in one such experiment, 25–30% of the sperm resumed swimming in 8 mM Li^+ after addition of 10 μM cyclic AMP, whereas only 0–5% regained motility in 16 mM Li^+. Addition of 10 μM cyclic GMP instead of cyclic AMP did not reverse the Li^+ inhibition. Also, addition of 10 μM cyclic AMP to control sperm reactivated without Li^+ had no noticeable effect on either the waveforms or frequency in the conditions tested.

To determine whether motility depends on the continuing synthesis of cyclic AMP by adenylate cyclase in normal preparations and whether the inhibition of motility by Li^+ is linked to inhibition of this activity, we replaced the ATP in our reactivating solution with analogues lacking a 3′-hydroxyl group that cannot serve as substrates for adenylate cyclase. Both 3′-deoxy ATP and 2′,3′-dideoxy ATP (at 1.0 mM) induce flagellar beating at about 13 Hz and 9 Hz, respectively, with waveforms and longevity very similar to those obtained with ATP. Moreover, this reactivated motility is inhibited by Li^+, although concentrations of 10–20 mM are required, suggesting that the affinity of these analogues for Mg^{2+}, Li^+, or for dynein ATPase is different from that of ATP. It seems, therefore, that while Li^+ may block adenylate cyclase activity, this is not the mechanism by which it inhibits flagellar motility.

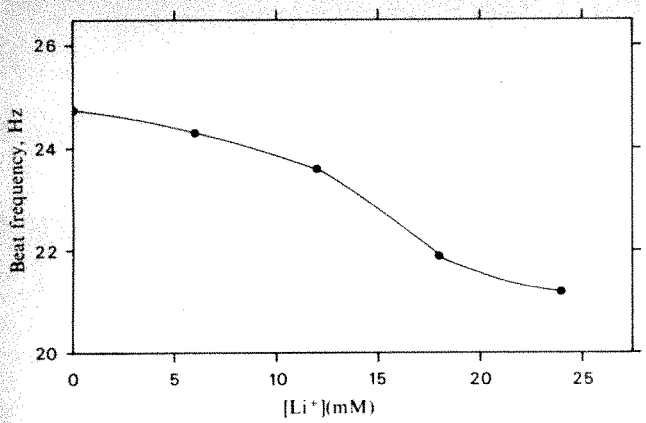

Fig. 2 Decrease in beat frequency as a function of Li^+ concentration of sperm restored to motility by trypsin digestion. Sperm were demembranated and reactivated as described in Fig. 1 legend, then inhibited by addition of Li^+ from 0 to 24 mM, followed by addition of 0.2 μg ml^{-1} trypsin. Beat frequencies were read ~2–3 min later, when the flagellar beating most closely resembled that of normal waves. Beyond this period, the movement began to deteriorate until finally the sperm stopped at ~5 min.

Our overall data thus favour a mechanism in which cyclic AMP increases the threshold concentration for Li^+ inhibition of motility, possibly through changing the activation level of the flagellum, while having little effect on the concomitant Li^+-induced reduction in beat frequency and increase in waveform asymmetry.

Further experiments were designed to test whether Li^+ inhibits dynein arm cross-bridge cycling or ATPase activity. First, we investigated the effect of Li^+ on sperm flagella set into rigor bends in reactivating solution lacking ATP[15], and found that the presence of Li^+ up to 80 mM did not block the straightening of rigor waves that occurred on subsequent addition of 1 mM ATP. Second, we measured the effect of Li^+ on the rate of hydrolysis of Mg-ATP^{2-} by solubilized latent activity dynein 1, and found that it decreased by only 15% in the presence of 4–64 mM Li acetate. On the other hand, the rates of Mg-ATP^{2-} hydrolysis for motile and non-motile (homogenized) preparations of reactivated sperm[16] were decreased from 0.14 ± 0.01 and 0.035 ± 0.005 μmole P_i per min mg protein, respectively, to 0.017 ± 0.003 and 0.013 ± 0.004 μmol P_i per min mg protein in the presence of 10 mM Li^+ in 0.2 M K acetate at *p*H 8.2. The Li^+-induced decrease in ATPase activity of motile sperm preparations presumably reflects a loss of movement-coupled ATPase activity resulting directly from immobilization of the sperm flagella.

Our results indicate Li^+ does not inhibit dynein arm cycling *per se*, but rather interacts with a regulatory mechanism—this is shown most clearly by the fact that brief digestion desensitizes the reactivated sperm to inhibition by Li^+. As low concentrations of Li^+ mimic the effects of Ca^{2+} in inducing asymmetrical beating and quiescent-shaped waveforms, it seems likely that at least one of the regulatory sites concerned is that which normally modulates the Ca^{2+}-dependent asymmetry of flagellar waveform. Besides Ca^{2+} (ref. 3) and Li^+, the only agents known to inhibit flagellar motility without inhibiting dynein arm cycling activity are CO_2 (ref. 17) and low *p*H[18]. The targets for these agents are unknown, but CO_2 appears to act through an amplitude-regulating mechanism.

The depression of beat frequency (0–13%) that follows desensitization by trypsin in Li^+ concentrations ranging from 0 to 24 mM probably results from a decreased Mg-ATP^{2-} concentration as a consequence of the formation of Li-ATP^{3-}. We calculate that with 6 mM Li^+ added to our reactivating solution, the concentrations of Mg-ATP^{2-} and Li-ATP^{3-} become 0.45 and 0.14 mM, respectively[19], and by direct measurement we have found that Li-ATP^{3-} is not hydrolysed by soluble dynein 1 at a significant rate. However, our present data do not allow us to say whether Li^+ or Li-ATP^{3-} is the primary form responsible for the increased asymmetry and inhibition of motility in non-trypsin-treated sperm. The apparent competition of free Mg^{2+} or Ca^{2+} with Li^+ could be due to competition for complexing with ATP. However, because many of its effects resemble those of Ca^{2+}, we postulate that Li^+ may be acting as an analogue of Ca^{2+} at a regulatory site that binds Ca^{2+} at elevated Ca^{2+} concentrations, and Mg^{2+} at low Ca^{2+} concentration[20]. Okuno and Brokaw reported similar difficulty in determining whether Ca^{2+} or Ca-ATP^{3-} interacts with the axoneme to induce either asymmetrical beating, or non-oscillatory beating in the presence of vanadate[21].

Our work suggests that further study of the effects of Li^+ on cyclic AMP- and Ca^{2+}-dependent regulatory steps may have broad usefulness in unravelling the complex interactions involved in the control of flagellar motility and other cellular functions.

We thank Dr Mary E. Porter for valuable discussions. This research was supported by NIH grant HD 06565.

Several hormones and neurotransmitters raise the cytosolic free Ca^{2+} concentration by stimulating the influx of Ca^{2+} and/or by mobilizing stored Ca^{2+} (refs 1, 2). However, the link between the agonist receptor on the cell surface and the organelle(s) from which Ca^{2+} is mobilized is unknown. One feature of the agonists that increase cytosolic Ca^{2+} is their rapid induction of phosphatidylinositol turnover[3–8] and polyphosphoinositide hydrolysis[9–14]; in some tissues this leads, within seconds, to a marked accumulation of the water-soluble products, inositol 1,4-bisphosphate (Ins1,4P_2) and inositol-1,4,5-trisphosphate (Ins1,4,5P_3)[15–18], suggesting that these might mediate Ca^{2+} mobilization from internal pools[17,18]. Such an action of Ins1,4,5P_3 has recently been inferred from studies with permeabilized pancreatic acinar cells[19] and

hepatocytes[20,21]. Here we show directly that Ins1,4,5P$_3$ rapidly releases Ca^{2+} from a microsomal fraction of rat insulinoma but not from mitochondria or secretory granules. Moreover, this response is transient and desensitizes the microsomes to subsequent Ins1,4,5P$_3$ additions. These results suggest that Ins1,4,5P$_3$ functions as a cellular messenger inducing early mobilization of Ca^{2+} from the endoplasmic reticulum.

The ambient free Ca^{2+} concentration, $[Ca^{2+}]$, of the incubation medium maintained by the microsomes was determined using a Ca^{2+}-specific minielectrode[22]. We determined the specific activities of the apparent net Ca^{2+} uptake and of marker enzymes in four fractions obtained after centrifugation of the resuspended microsomes on a sucrose density gradient. Ca^{2+} transport activity correlated strongly with the endoplasmic reticulum enzyme marker but not with the plasma membrane marker (Fig. 1). This demonstrates that the high Ca^{2+} transporting activity of the insulinoma microsomes is localized mainly in the endoplasmic reticulum. As the experiments shown in Fig. 1 required long preparation times and such a large number of insulinomas, all subsequent work was carried out on the original microsomal fraction.

Figure 2*a* shows that insulinoma microsomes lowered the ambient free Ca^{2+} from ~1.5 μM to ~0.1 μM. At this point a pulse addition of Ins1,4,5P$_3$ resulted within 20 s in an increase in medium free Ca^{2+} to ~0.25 μM, followed by a decrease, representing Ca^{2+} re-uptake. Interestingly, a second addition of Ins1,4,5P$_3$ produced only a very small increase in $[Ca^{2+}]$, indicating that the increase in $[Ca^{2+}]$ after the first Ins1,4,5P$_3$ addition was not due to Ca^{2+} contamination of the compound. When a smaller, first pulse addition of Ins1,4,5P$_3$ was made, producing only a modest transient increase in medium $[Ca^{2+}]$, a second addition of Ins1,4,5P$_3$, even at a maximal concentration, elicited only a very small Ca^{2+} response (Fig. 2*b*). Similar observations were made whether the second addition occurred immediately after the first one or 40 min later. The reason for this phenomenon is unknown; it could conceivably reflect the process of densensitization, which is a feature of Ca^{2+}-mobilizing agonists[6]. Alternatively, during the first stimulation, an Ins1,4,5P$_3$-sensitive vesicle population released Ca^{2+} which was sequestered by a separate population insensitive to the action of Ins1,4,5P$_3$. A third possibility is that it was caused by a rapid degradation of Ins1,4,5P$_3$ and/or the appearance of degradation products of Ins1,4,5P$_3$. Experiments were done to explore this latter hypothesis. When microsomes were incubated in the presence of 9 μM Ins1,4,5 [4,5-^{32}P]P$_3$ (prepared and analysed as described previously[16,23]), 85 ± 7% (n = 3) of the label remained after 10 min, indicating that degradation was too slow to account for desensitization. Furthermore, the degradation products of Ins1,4,5P$_3$, that is, Ins1,4P$_2$, Ins1P and *myo*-inositol, all at a concentration of 10 μM, did not desensitize the microsomes to a subsequent Ins1,4,5P$_3$ addition.

The half-maximal effective concentration of Ins1,4,5P$_3$ was 3 μM and the maximal concentration was ~10 μM (Fig. 3). These values are somewhat higher than those reported for permeabilized pancreatic[19] and liver cells[20,21]. The ability to mobilize Ca^{2+} seems to be specific for the trisphosphate derivative because there was no release of Ca^{2+} on addition of Ins1,4P$_2$ (prepared as described previously[19,23]), Ins1P or *myo*-inositol, all tested at 10 μM (data not shown).

To test the organelle specificity of the response, insulinoma mitochondria were incubated in conditions similar to the microsome. The mitochondria buffered the ambient $[Ca^{2+}]$ to ~0.9 μM[22]. Ins1,4,5P$_3$ did not induce Ca^{2+} release nor did it change the extramitochondrial Ca^{2+} steady state. Ins1,4,5P$_3$ was not tested at a very low Ca^{2+} concentration (0.1 μM) as this causes Ca^{2+} depletion of the mitochondria. Secretory granules were unable either to lower the medium $[Ca^{2+}]$ or to take up a pulse addition of Ca^{2+}. Furthermore, of the large amount of Ca^{2+} that the secretory granules were found to contain on isolation, none was released by Ins1,4,5P$_3$. Thus, neither insulinoma mitochondria nor secretory granules appear to be sensitive to Ins1,4,5P$_3$.

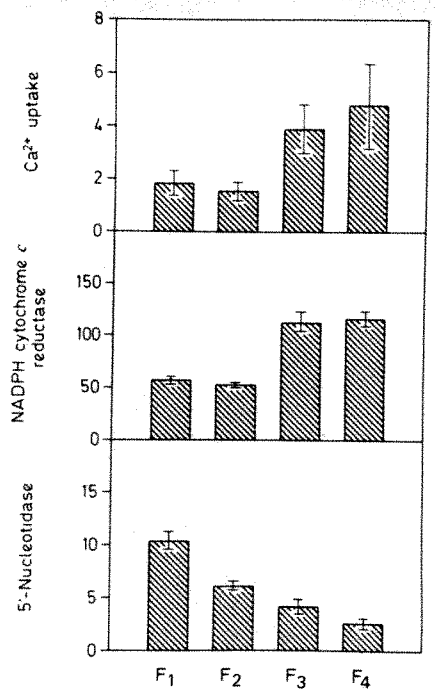

Fig. 1 Specific activities of MgATP-promoted Ca^{2+} uptake and of marker enzymes in four fractions obtained after centrifugation of the resuspended microsomal fraction on a discontinuous sucrose density gradient. Ca^{2+} uptake (nmol of Ca^{2+} per min mg protein) in the four fractions was measured with the same amount of material (0.2 mg protein ml^{-1}), as in Fig. 2 legend. The amount (nmol) of Ca^{2+} taken up by the four fractions was calculated from the reduction of the ambient free Ca^{2+} concentration on addition of each separate fraction (see also Fig. 2). For NADPH cytochrome *c* reductase, units are nmol of cytochrome *c* reduced per min mg protein; for 5′-nucleotidase, units are μmol adenosine formed per h mg protein. Values are the mean ± s.e. of four experiments.
Methods: Insulinomas were removed from rats[27,28], then dissected and homogenized as described previously[22]. Microsomes were obtained from the supernatant following three successive centrifugations: 1,500*g* for 5 min, 9,800*g* for 10 min, and 24,000*g* for 20 min. The resulting supernatant was centrifuged at 100,000*g* for 60 min to obtain a microsomal pellet. This fraction was enriched in NADPH cytochrome *c* reductase by 2.6-fold compared with the homogenate, 3.6-fold in 5′-nucleotidase, 0.01-fold in cytochrome *c* oxidase and 1.3-fold in immunoreactive insulin, the respective markers of endoplasmic reticulum, plasma membrane, mitochondria and secretory granules plus reticular structures. The microsomal pellet was gently washed (without disturbing the pellet) three times with medium containing 0.25 M sucrose, 5 mM HEPES *p*H 7.0 (sucrose medium) and resuspended in 0.1 ml of the sucrose medium, kept on ice and used immediately for Ca^{2+} transport experiments. In a separate series of experiments, resuspended microsomes were layered onto the surface of a discontinuous sucrose density gradient (1.5 ml of the densities 1.10, 1.14, 1.16, 1.20) and centrifuged at 150,000*g* for 90 min. Four discrete bands observed at the density interfaces were collected for protein, Ca^{2+} flux and enzyme marker determinations. These fractions were numbered 1–4 in order of increasing density (F_1–F_4). For the isolation of insulin secretory granules, the postnuclear supernatant was centrifuged at 23,700*g* for 15 min. The resultant pellet was resuspended, layered and centrifuged on a 30% Percoll gradient as described previously[22]. As the bottom of the gradient (see ref. 22) contained mainly insulin secretory granules, this fraction alone was collected. The final secretory granule pellet was obtained after three successive washings in sucrose medium at 23,700*g* for 15 min. The secretory granule fraction was enriched compared with the homogenate 11.2-fold in insulin, 1.1-fold in cytochrome *c* oxidase and 0.3-fold in NADPH cytochrome *c* reductase. Cytochrome *c* oxidase was assayed according to ref. 29; NADPH cytochrome *c* reductase was measured as described previously[30]; and 5′-nucleotidase was measured by the technique of Avruch and Wallach[31]. Immunoreactive insulin was assayed according to a method described previously, using rat insulin as standard[32]. Proteins were determined by the Coomassie blue method using a commercial kit (Bio-Rad).

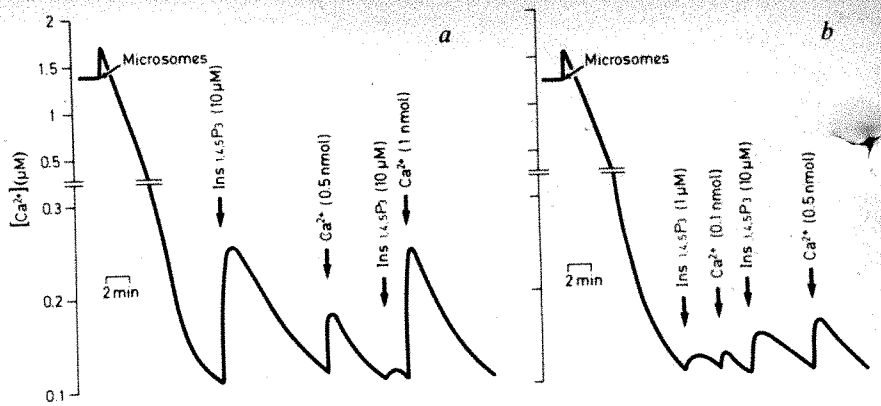

Fig. 2 Extramicrosomal ambient free Ca^{2+} concentration maintained by insulinoma microsomes: effect of Ins1,4,5P_3. Microsomes were incubated at 30 °C, *p*H 7.0 in 200 μl of a buffer containing 110 mM KCl, 2 mM KH_2PO_4, 25 mM HEPES, 1 mM $MgCl_2$, 1 mM MgATP, 3 mM creatine phosphate, 50 μg ml^{-1} creatine kinase, 0.2 μM antimycin and 0.5 mg ml^{-1} of bovine serum albumin, with continuous stirring. The medium [Ca^{2+}] was continuously recorded with a Ca^{2+}-selective minielectrode made and calibrated as described previously[22]. Where indicated, microsomes (0.75 mg protein ml^{-1}), Ins1,4,5P_3 or $CaCl_2$ (nmol per 200 μl) (in the amounts indicated) were added to the medium. Within 10 min, microsomes lowered the extramicrosomal ambient free Ca^{2+} concentration to ~0.1 μM; they were not easily saturated with Ca^{2+} as they could rapidly take up several sequential pulse additions (5 nmol per mg protein) of Ca^{2+}. The Ca^{2+} accumulated could be rapidly released by adding the Ca^{2+} ionophore A23187 (1 μg ml^{-1}) or by lowering the ATP present in the medium by the addition of glucose (5 mM) plus hexokinase (20 U ml^{-1}), indicating that Ca^{2+} is accumulated into vesicular elements in a MgATP-dependent manner (not shown). If microsomes were preincubated with the Ca^{2+} ionophore A23187 to empty the vesicles of Ca^{2+}, the addition of Ins1,4,5P_3 produced only a very small increase in medium [Ca^{2+}]. This amount of Ca^{2+} corresponded to a similar increase in [Ca^{2+}] when Ins1,4,5P_3 was added to the incubation buffer alone; it averaged ~5–10% of the effect shown in *a* and was accounted for in the subsequent calculation. Ins1,4,5P_3 was obtained by alkaline hydrolysis of ox brain phosphatidylinositol-4,5-bisphosphate, followed by preparative paper chromatography (R.F.I. and M.J.B., in preparation). The figure shows representative experiments which were repeated at least eight times.

Three lines of evidence suggest that Ins1,4,5P_3 induces Ca^{2+} release from the endoplasmic reticulum and not from plasma membrane vesicles contaminating the microsomal fraction. First, the insulinoma microsomal Ca^{2+} uptake correlated well with the endoplasmic reticulum enzyme marker, but not at all with the plasma membrane marker. Second, the amount of Ca^{2+} released by Ins1,4,5P_3 (10 μM) was 6.1 ± 0.2 nmol per mg protein (mean ± s.e. of six separate experiments). This is a considerable amount of Ca^{2+}—for comparison, most tissues, including pancreatic islets[1,2], have a total calcium content of ~20 nmol per mg protein. The Ca^{2+} is, therefore, unlikely to originate quantitatively from contaminating plasma membrane vesicles, in a tissue that is particularly rich in reticular structures such as insulinoma cells. Third, Ins1,4,5P_3 mobilizes Ca^{2+} in permeabilized pancreatic acinar and liver cells in which the plasma membrane should not function as a Ca^{2+}-storing organelle[19–21]. However, the possibility that Ins1,4,5P_3 could induce in intact cells an influx of external Ca^{2+} should not be precluded.

Agonist-induced rises in intracellular free [Ca^{2+}] have been universally associated with an enhancement of both phosphatidylinositol turnover and polyphosphoinositide hydrolysis[3–18]. More recent observations of a resultant, rapid, Ca^{2+}-independent generation of water-soluble inositol phosphates, have led to the hypothesis that these compounds could act as intracellular messengers mobilizing cellular Ca^{2+} stores[17,18]. This hypothesis is substantiated and extended by the present report. We have shown that Ins1,4,5P_3, at concentrations which are thought to occur in cells, can increase, within 20 s, the extramicrosomal concentration of Ca^{2+} from 0.1 μM to ~0.2–0.3 μM, corresponding respectively to basal or stimulated conditions in a variety of tissues[24–26]. The results of the present study strongly suggest a specific role for Ins1,4,5P_3 as a cellular messenger inducing Ca^{2+} release from the endoplasmic reticulum.

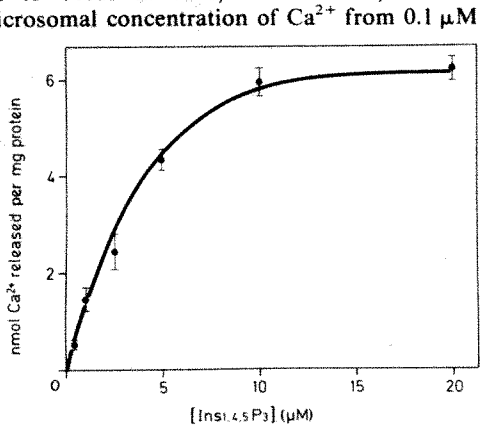

Fig. 3 Dose–response of Ins1,4,5P_3-induced Ca^{2+} release. Pulse additions of various known amounts of $CaCl_2$ (as shown in Fig. 2) were used to calibrate the Ca^{2+} rapidly released by Ins1,4,5P_3. Values are the mean ± s.e. of three separate experiments.

We thank Nicole Challet, Janine Bassi and Charles Jorand for technical assistance. This work was supported by grant 3.246-082SR from the Swiss NSF.

BIOLOGY OF KNOWLEDGE

The Evolutionary Basis of Reason

by **R. Riedl,** *Zoological Institute, University of Vienna, Austria*

Since human reason cannot give a rational account of its own rationality, it must be sought through an explanation of the biological development of our rational equipment. Knowledge can be acquired both through the evolutionary process and by the individual, and this enables us to assess in what respect human reason can be unreasonable.
In studying the phylogenetic history of reason and the way in which reason functions in the acquisition of knowledge, we can see through opposing philosophical doctrines such as empiricism and rationalism, or materialism and idealism. Moreover, Kant's *a priori* turns out to be the result of *a posteriori* selection in the development of our own ancestry.

Contents: Foreword; Preface to the English Edition; Introduction; Biology and Cognition; The Hypothesis of Apparent Truth; The Hypothesis of the Comparable; The Hypothesis of the First Cause; The Hypothesis of the Purposeful; Of Solutions and Their Consequences; Appendix: Notes; Glossary; References; Author Index; Subject Index.

CELL BIOLOGY

by **N.O. Thorpe,** *Augsburg College*

The book examines the detailed structures of all elements of the cell, relating them to their respective functions. It discusses organelles of the cell at the microscopic, ultrastructural and molecular levels, and shows how organelles contribute toward the normal functioning of the intact cell. The text is uniquely organized, moving from discussions of the cell exterior to considerations of the interior structures and mechanisms.

VIBRIOS IN THE ENVIRONMENT

edited by **R.R. Colwell,** *University of Maryland*

This is the only comprehensive book on the subject providing a synthesis of the available information on marine and freshwater bacteria which cause cholera. It covers epidemiology and pathogenesis, the molecular genetics of cholera-causing bacteria and their interaction with the environment, methods for isolation, culture and identification, and much more. It presents the practical implications of the research in sections on prevention of vibrio transmission, and analytical methods for detection and monitoring.

ECOLOGY OF TROPICAL PLANTS

by **M.L. Vickery**

This textbook for students and practitioners of tropical ecology, botany, biogeography and agriculture describes each aspect of the physical and organic environment of tropical plants, and the effect of Man's activities on the plant environment. There are chapters devoted to soil, water, atmospheric gases, interactions with animals and other plants and the effects of man on tropical vegetation and the plant environment. Tropical plant habitats are described, including rain forest, deciduous forest, montane forest, savanna, desert, swamp and salt lake.

Contents: Introduction; Plants and Soil; Plants and Water; Plants and Radiation; Plants and the Atmosphere; Tropical Vegetation; Interactions Between Plants; Plants and Animals; Plants and Man; Investigating the Environment (by J. Hall, University of Dar Es Salaam, Tanzania).

BIOLOGY OF COMPLEX CARBOHYDRATES, Volume 2

edited by **V. Ginsburg,** *National Institutes of Health, Bethesda, Maryland,* and **P.W. Robbins,** *MIT*

This volume provides an integrated picture of the diverse roles played by carbohydrates in the structure and function of biological systems. It provides an overview of carbohydrate research involving lectins, and discusses the emerging structural patterns of carbohydrates found in glycoproteins, and the related biosynthetic pathways. The book summarizes the extraordinary progress made in the past few years on the determination of carbohydrate structure and conformation by nuclear magnetic resonance spectroscopy.

Contents: Lectins-Properties and Applications to the Study of Complex Carbohydrates in Solution and on Cell Surfaces; The Carbohydrates of Glycoproteins; Biosynthesis of Glycoproteins: Formation of N-Linked Oligosaccharides; Biosynthesis of Glycoproteins: Formation of O-Linked Oligosaccharides; The Three-Dimensional Structure of N-Linked Oligosaccharides; Index.

A NEW ECOLOGY

Novel Approaches to Interactive Systems

edited by **P.W. Price, C.N. Slobodchikoff,** and **W.S. Gaud,** *all of Northern Arizona University*

Leading experts examine four rapidly developing areas in ecology emphasizing new approaches, foundations, and opportunities for new research. The book examines the relationship between resources and populations, life history strategies, ecology of social behavior, and organization of communities.

0471 89670 5 528pp April'84 £56.95

NEW PHENOLOGY

Elements of Mathematical Forecasting in Ecology

by **A.S. Podolsky,** *Ben-Gurion University, Israel*

An easy-to-use text/reference which presents the methods for forecasting the dates of development of plants and cold-blooded animals (especially insects). In addition to its theoretical interest and value in ecological modeling, phenology has important applications in crop disease and pest control and crop modeling.

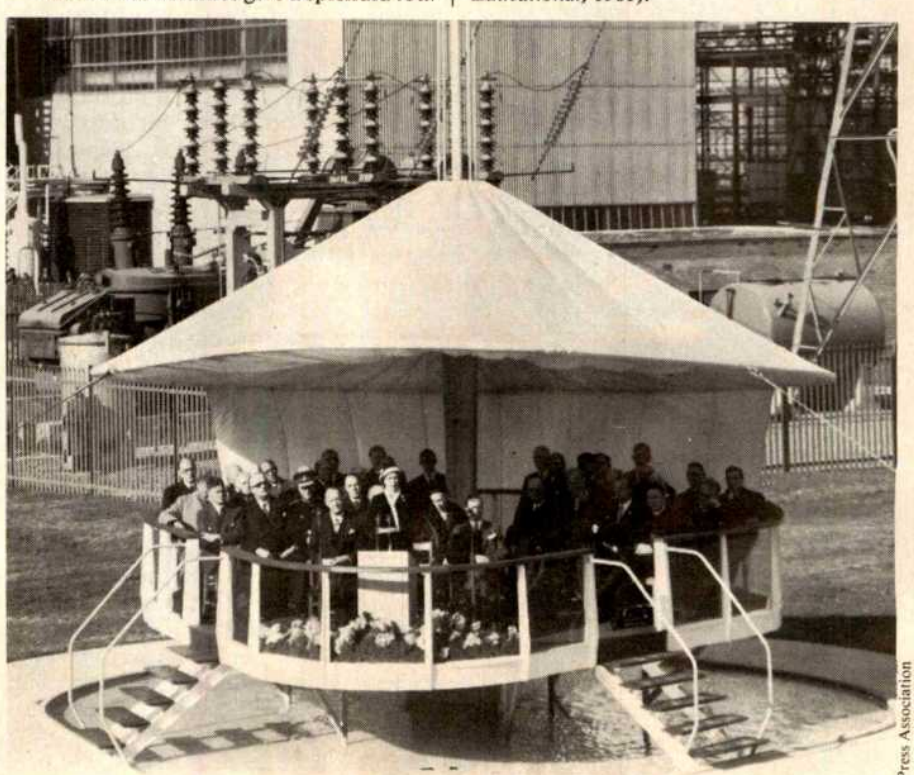
Alan Cottrell

Nuclear Power Technology (in three volumes). Edited by W. Marshall. *Oxford University Press: 1984. Vol.1* Reactor Technology, *pp.503; Vol.2* Fuel Cycle, *pp.456; Vol.3* Nuclear Radiation, *pp.363. Each volume £35, $65.*

WITHIN this work is an honest tale, plainly told. Therein lies both its strength and weakness. Its strength is that of the scientific tradition for unvarnished presentations of facts, letting them speak for themselves uncoloured by rhetoric, unstrained by advocacy, unheated by passion, unbiased by prejudice. For those raised in the scientific culture this is the natural, indeed the inevitable, mode of expression; the anvil on which every scientific deduction can be mounted and exposed to the hammer of critical analysis. Its weakness is that the scientific culture is a minority one. The great world which fashions public opinion — the world of hyperbole and shock-horror, of the self-inflated politician, bombastic trades union leader, committed journalist, trendy teleperson — resonates to a different sound. The anti-nuclear lobby know this full well. They are at home in this world and play its tunes as captivatingly as any Pied Piper.

Thus there is the extraordinary position today — nearly a third of a century after Calder Hall first brought nuclear electricity to Britain, a period in which the nuclear industry has gained a brilliant achievement in supplying cheap power, reliably and safely — that the nuclear industry is on the defensive, trying to justify itself to the general public in the only way it knows, with the quiet voice of scientific reason. For, as Sir Walter Marshall says in his preface to the three volumes, the aim was to prepare a work on nuclear power orientated towards increasing public knowledge and for the public interest. The project was conceived at a time when the United Kingdom Atomic Energy Authority, of which the then Dr Walter Marshall was Chairman, was approaching its twenty-fifth anniversary (in 1979). This event could have justified a little trumpet-blowing, but instead the decision was to review the state of nuclear science and technology in the classical scientific manner.



This is done in 24 chapters, each by different authors who come almost without exception from within the UKAEA. Such a division of the labours is probably the only way to deal comprehensively and authoritatively with such a huge and wide-ranging subject. It has of course the usual advantages and disadvantages. On the merit side each individual topic is given a chapter and author(s) to itself, and so enjoys a reasonably self-contained exposition which can be read separately from the rest of the contents; against this, there is inevitably some repetition of underlying points that are common to more than one chapter.

The eight chapters in Vol.1 deal with nuclear reactors. After two introductory contributions, which outline the underlying physics and assess the current status of thermal and fast reactors — and go surprisingly far into the mathematics of neutron physics, in a work intended for the public — the various main reactor types are described, namely gas-cooled, light water, fast and heavy water. Two final chapters deal with novel reactor concepts, for example fluid-fuel reactors, and briefly with prospects for fusion power. Volume 2 covers the various aspects of the fuel cycle — occurrence, supply and enrichment of uranium, fuel design and fabrication, reprocessing, waste management, decommissioning, thorium fuel cycles — in similar style. Volume 3, which is perhaps of greatest interest to the general public, deals with various aspects of nuclear radiation — biological, detection, environmental, risk assessment, medical radioisotopes. Radioactive dating is also covered, although surprisingly there is no chapter on the use of gamma radiation in industry or on non-medical applications of radioisotopes.

These three volumes give a splendid *tour d'horizon* of the science and technology of nuclear power. Not surprisingly, given their provenance, the expositions centre round British experience and points of view. Nevertheless much of the treatment is sufficiently general as to be of interest to readers in other nations, especially in countries having light-water reactors, for these are dealt with almost as fully as gas-cooled reactors. The treatment of fast reactors is also detailed. Perhaps, if only in fairness to the outstanding Canadian effort, there might have been a little more about the excellent CANDU reactors.

Finally, however, the questions which began this review raise themselves once more. I am sure that many people within the nuclear industry, as well as some scientists and engineers outside it, will read these books with both pleasure and profit. But will the general public and all those publicity-seeking pundits who pronounce so readily and volubly on all matters nuclear? I doubt it. The first group probably does not have the time to digest all the facts so fully gathered together here. The second bask in their unfettered imaginations and have no need of facts. The best response I can make to this work is to thank the authors for a noble effort, which has produced a fine work of science, and to tell them that something entirely different is needed to win the hearts and minds of the great majority in the non-scientific culture. □

Sir Alan Cottrell is Master of Jesus College, Cambridge. Among other books he is author of How Safe is Nuclear Energy? (*Heinemann Educational, 1981*).

Day of confidence — Wednesday 17 October, 1956, and the Queen opens Calder Hall, the first full-scale nuclear power station.

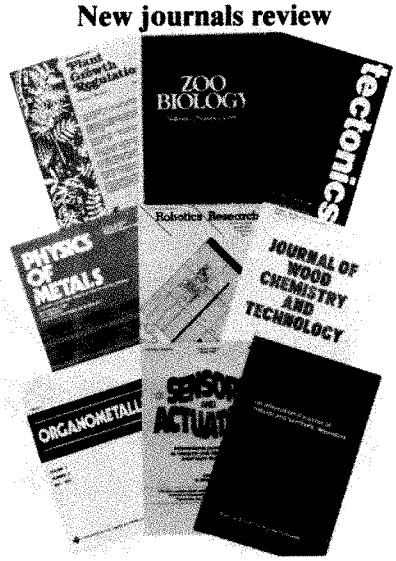
Hormone balance

S.J. Simpson

Endocrinology of Insects. Invertebrate Endocrinology, Vol.1.
Edited by Roger G.H. Downer and Hans Laufer.
Alan R. Liss/Wiley: 1984. Pp.707. $199.80, £111.

ONE of the most daunting tasks in biology would be to prepare a volume entitled *Endocrinology of Insects*. So daunting, in fact, that until now no one has attempted to do more than review selected aspects of what is an enormous, complex and rapidly expanding field. Downer and Laufer have approached the problem of producing a detailed, scholarly review of the subject in exactly the right, and probably the only way: they have asked specialists to cover defined ground.

The resulting volume deals with the nature of endocrine glands and neurosecretory cells; the chemistry and biosynthesis of hormones, and their interaction with target cells; intracellular second-messengers; the physiological role of hormones; myotropic and neurotropic substances; pheromones; the relevance of insect hormones in plants; and the usefulness of hormones in insect control. Inevitably there are omissions, and problems of redundancy and lack of continuity, but the volume as a whole is a success. The differing interpretations and standpoints expressed by the contributors do, as the editors claim, provide depth and balance to the work.



Endocrinology of Insects is not easy to read; not, in most cases, because the writing is unclear, but because the authors have done justice to their topics. This approach has often precluded the drawing of generalizations or syntheses. Even the introductory overviews for such sections as "Regulation of Metamorphosis", "Regulation of [Female] Reproduction" (unfortunately male reproduction is not represented) and "Metabolic Homeostasis" are, by necessity, unable to do more than draw together information in a superficial sense. In most cases, not enough is known to generalize, and what *is* known is often conflicting — different species use the same hormone for different purposes; different strains of the same species, and even a single strain under different rearing regimes, give conflicting results; it is difficult to distinguish real effects from those stemming from dissection and bioassay techniques; and there is a danger that phenomena are attributed to a particular hormone when in fact the hormone is acting at an earlier stage in a causal sequence involving other endocrine and neural factors. More aspects of insect endocrinology will, perhaps, soon begin to gel, but the cautious approach of many of the contributors is generally justified.

An unusual aspect of the book is the coverage of areas about which virtually nothing is known. Thus the section on metabolic homeostasis includes three detailed chapters on excretion, on lipid metabolism and on carbohydrate metabolism, along with a chapter on nitrogen metabolism in which the word hormone is almost absent. Such a contrast emphasizes those areas which are poorly understood and puts the better known subjects in perspective. The quest for completeness has its drawbacks, however. For example, neurotransmitters, neuromodulators and pheromones differ from hormones in degree rather than kind and the editors have chosen to represent them but briefly — in the case of pheromones, too briefly to be of much use.

I would have liked more thorough cross-referencing between chapters, but that apart my main worry is that the book is two years out of date. Nonetheless, *Endocrinology of Insects* is a very important work. An understanding of hormonal mechanisms is essential to anyone who studies insect behaviour or physiology, and this book makes a difficult subject accessible to us all. □

S.J. Simpson is Demonstrator in the Department of Zoology, University of Oxford.

New journals review

On 27 September *Nature* will publish the fourth annual review supplement devoted to science journals.

Criteria for inclusion of a journal in the 1984 issue are that:

(i) the first number appeared, or the journal was retitled, *between June 1982 and May 1983* (the second cut-off date allows at least three issues of a journal to have been published, the minimum number on which a reasonable judgement can be based);

(ii) it is published at least three times a year;

(iii) the main language used is English.

Publishers and learned societies are invited to send *four different issues of each suitable periodical, including the first and most recent numbers* (if from outside the United Kingdom, by air mail) to: The Review Editor, *Nature*, 4 Little Essex Street, London WC2R 3LF, England. Subscription details, if possible for both 1984 and 1985, should be included.

Screening methods of recombination

E.J. Wood

The Techniques in Genetic Engineering Video Library. TGE 1: Nucleic Acids Techniques — An Overview.
By Stephen D.M. Brown.
IRL Press: 1984. Formats available: PAL in VHS and Betamax, £80, $160. U-matic copies £7.50, $15 extra. Supplementary charge for NTSC and SECAM standards conversions.

THIS 25-minute videotape is the first of a series of eight* which will deal with the techniques of genetic engineering. Viewed in isolation from the rest of the programmes (which will appear later this year), it gives a foretaste of the high quality of production of the series, but tells us less about what can be expected of the content and level of the subsequent tapes. Nor is it yet clear how easily a student could proceed from instruction of this type to actual work in the laboratory.

The programme starts with a graphic display of a computer-generated DNA double helix, the introductory section then featuring a series of stills during which the voice-over talks about the impact of genetic engineering and its potential and limitations. A brief interview with Sir Gordon Wolstenholme gives an historical view of developments since Watson and Crick, and stresses that no one really saw any practical uses for the techniques of genetic manipulation until seven or eight years ago.

Following on, the fundamental techniques underlying recombinant DNA technology are explained, namely the use of restriction enzymes, of sticky ends and of ligases. The use of restriction enzymes is well illustrated with graphics, although I wonder if it is really necessary at this level to speak about the different classes of restriction enzyme. Analysis by restriction mapping is demonstrated, and from this a student would readily get a good feel for how slabs of agar are used in electrophoresis, blotting and so on. On the whole this section is evenly paced, well-explained and clearly photographed.

The next section deals with the cloning of DNA into a phage in order ". . . to look at a single gene". Graphics show the ligation of a section of "human" DNA into phage DNA, reinforcing what had been explained in the previous section. However at this stage the graphics seem to get out of phase with the voice-over: while the latter talks about plaques in a lawn of bacteria, the graphics show thousands of virus particles.

* Titles to follow are *Gene Analysis and Southern Blotting; DNA Sequencing with M13; Gene Libraries; Expression of Cloned Genes; Oligonucleotides — Their Use in Gene Cloning; Site-Specific Mutagenicity;* and *Microdissection and Microcloning.*

This section of the programme is the most uneven — speeding through a number of techniques (clone selection, blotting, hybridization, DNA sequencing) would surely leave the student wondering what the techniques are for and not really knowing how to carry them out. No doubt such details come in a later programme, but here the producers should have resisted the temptation to pack in so much detail.

The pace then slows down, as *c*DNA cloning is dealt with briefly but adequately, but speeds up again as we launch into monoclonal antibodies and start injecting things into *Xenopus* oocytes. Well, it *is* an overview; but again I would have been happier had the desire to mention almost every technique been stifled.

The final section largely uses stills with voice-over to try to answer the question: "Why is industry so interested in all this?". Topics include improving the quality of plant proteins, mineral extraction, "improved" bacteria for energy production from plant waste and for degrading pollutants, as well as interferon and insulin production. Much credit is given to genetic engineering (at the molecular level) for doing, or potentially doing, all of these things; but it is, I think, churlish, if not inaccurate, to fail to mention that for centuries plant and animal breeders have been messing around with the genetic constitutions of species in order to "improve" them.

Also included in the final section is a description of how recombinant DNA technology may, and indeed is, being used in the diagnosis of inherited disease. How this is done is very clearly shown including a description of the analysis of DNA taken from chorionic villi using a DNA probe for prenatal diagnosis of a genetic defect.

Overall the programme gives a good indication for what can be done with recombinant DNA. The photography of the techniques is of a high standard, illustrating the advantage of film or videotape over "cold print" for demonstrating methodology, and most of the graphics are clear and straightforward. The speech, too, is clear and should easily be understood by those whose first language is not English. My main criticism is the unevenness of pace in some parts of the programme, but I would expect this to be less of a problem in subsequent tapes dealing with individual techniques in detail.

A little booklet accompanies the videotape and contains many of the graphics in printed form. These diagrams will be useful for students when revising the details of the techniques. However, while the booklet gives a warning that some of the reagents used are hazardous, neither tape nor booklet says that you should get the permission of a genetic manipulation committee before proceeding. Perhaps this comes later. □

E.J. Wood is a Senior Lecturer in the Department of Biochemistry, University of Leeds.

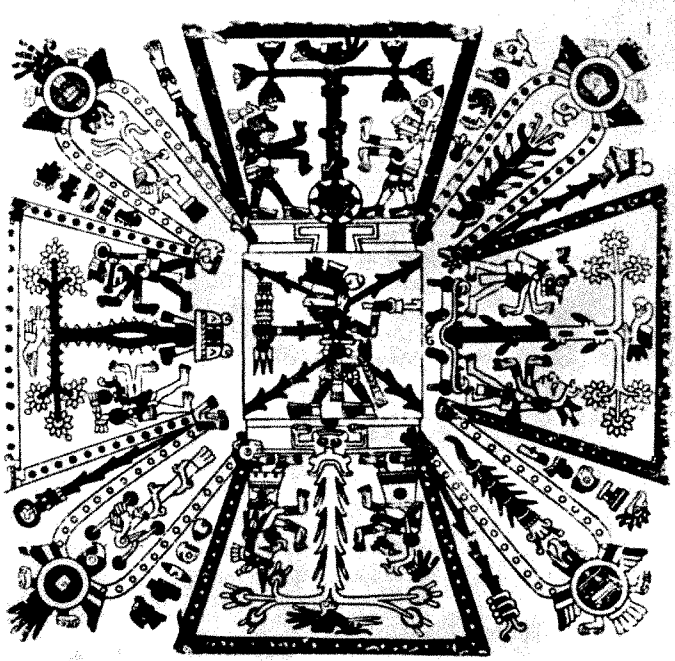
On ice and climate

Claus U. Hammer

The Climatic Record in Polar Ice Sheets.
Edited by Gordon de Q. Robin.
Cambridge University Press: 1983.
Pp.212. £32.50, $59.50.

GLACIERS move slowly. So, apparently, does the publication of monographs on polar ice sheets. In *The Climatic Record in Polar Ice Sheets*, an offspring of a workshop held in 1973, the subject is the information to be obtained on past climate from ice sheets, through the past 100,000–150,000 years with a few excursions further back into the Quaternary. The huge polar ice sheets are indeed slowly moving, frozen libraries of past atmospheric conditions, but the information they contain is written in a detailed, complex language. How far have we come in the translation of that language?

The aim of the workshop was to investigate the validity of data obtained from ice sheets, whether in the form of isotopic composition of ice cores or via measured temperature profiles along the corresponding boreholes. Such studies are complicated by the flow history of the ice, and changes in the isotopic composition of the ice can only in part be interpreted as changes in temperature. The book offers a great deal of detailed information on these problems, and a central much-needed contribution (Chapter 5) is devoted to ice flow and heat transport within the ice sheet.



The general reader may have difficulties getting through this account, though glaciologists will feel more at home. The model calculations presented are exemplified by ice core case-studies, but I suspect that current models and input parameters are not realistic enough to give safe answers; a lot more glacio-meteorological data are needed before climate may be accurately inferred from ice cores.

In other chapters the reader is given a guided tour of the ice library, but I cannot help feeling a little lost: lacking is an introductory chapter to place the enterprise within the general context of the Quaternary. Attempts to this end have been made in a chapter on ocean cores, but a broader discussion of time scales and variability of ocean core data would have been helpful. Nonetheless, the data presented in the book add much to our understanding of salient problems in this area. For example, the total gas content in air bubbles in the ice can indicate old surface elevations of the ice sheets, and surface studies of snow accumulations, temperatures and so on are clearly of importance.

The book's emphasis on the relationship between isotopes and borehole temperature profiles is more a reflection of its origin at a workshop in 1973 than of new developments. While contributions have been updated by the introduction of more recent results, they do not entirely conceal the fact that ten years have passed since the book was conceived. That being said, some of the most important findings in ice-sheet–climatic research since the 1960s *are* presented here, among them a number bearing upon still-controversial subjects.

This collection of ice-core data with its discussion of analytical methods is a must for climatic researchers. But to interpret much of the information found in the book such readers may require additional information from the glaciological literature. □

Claus U. Hammer is at the Geophysical Isotope Laboratory, University of Copenhagen.

The cosmological plan of the Aztec universe, laid out horizontally. The illustration shows the nine Lords and two hundred and sixty days of the Sacred Calendar assigned to the four cardinal directions, the centre of the universe, and sacred birds and trees. The illustration, reproduced from the *Codex Fejervary-Mayer I*, is taken from Brian M. Fagan's *The Aztecs*, an illustrated account of early Mexican life and culture. The book is published by W.H. Freeman, price hbk $27.95, £26.95; pbk $14.95, £13.95.

Evolution and us

John Beatty

Philosophy, Evolution and Human Nature.
By Florian von Schilcher and Neil Tennant.
Routledge & Kegan Paul: 1984. Pp.283. £16.95, $29.95.

THIS is a thought-provoking book — the result of a brainstorming collaboration between a philosopher (Tennant) and a behavioural geneticist and evolutionist (von Schilcher). The authors are mainly concerned with the ramifications of adaptationist accounts of human nature. They succeed in demonstrating what one might call (only partly tongue-in-cheek) the "resourcefulness" of the adaptationist perspective, and also do *pretty* well in countering current methodological and epistemological critiques of adaptationist theorizing. But their apparent reasons for making adaptation the centre of attention of a scientific study of human nature include some contentious views about evolutionary biology.

Following a long introduction to the structure and conceptual foundations of evolutionary theory (which is sound, but which could have been improved by incorporating at least *some* of the recent work in philosophy of biology), the authors turn their evolutionary lens upon their own kind — upon human values, cognition and language. As for values, they warn against the "naturalistic fallacy" of those who pretend to derive normative conclusions from purely evolutionary premises, but warn also against the "anti-naturalism" of those who believe that the facts of evolution are entirely irrelevant to ethics. As for cognition, they concentrate upon the "evolutionary exegesis of Kant": to what extent, they ask, are the categories of cognition grounded in neurological structures that are, in turn, the products of evolution by natural selection. They acknowledge, in this regard, some of the problems that result from "spiking" the brain with "an overly rich mixture of cognitive spirits". And, as for language, they are interested in the extent to which the individual development of grammatical skills "recapitulates" the phylogenetic history of grammatical innovations.

Adaptationist accounts of human nature are certainly worth entertaining. But I question a number of Tennant and von Schilcher's underlying reasons for pursuing such an approach, some of which seem to me to be based on serious misrepresentations of the structure and domain of evolutionary biology. First, they misconstrue evolutionary theory as being underpinned by nothing more than principles of natural selection, and evolutionary biology as being nothing more than the study of adaptations. Then they make unjustifiably bold claims about the domain of evolutionary biology — that is, about how much we can expect to explain in terms of evolution by natural selection.

For instance, among the "components" of the modern synthetic theory of evolution they include "The postulation of natural selection working on random genetic mutations as the one and only mechanism of evolutionary change" (p.97). And yet most versions of the Hardy–Weinberg law (the central principle of the synthetic theory) cite natural selection, mutation, migration, random drift and non-random mating as possible means of evolutionary change.

Even when von Schilcher and Tennant acknowledge alternative mechanisms of evolution, random drift for example, they belittle the search for such phenomena. For instance, they claim that

> the pan-selectionist point of view is the only possible working hypothesis. This is simply because someone not searching for a function [i.e. adaptation] will never find one, even if one should exist [p.63].

But surely it would be just as unlikely for someone to find an instance of random drift if they were not looking for it. In other words, there may be a good reason for saying that the pan-selectionist point of view is the only possible working hypothesis, but von Schilcher and Tennant have not provided it.

Finally, consider the authors' bold *a priori* extension of biological evolutionary theory to cultural evolution:

> *A priori* biological evolution is going to produce culturally adapted individuals when an important part of the environment is cultural; and genotypes placed in such environments will produce phenotypes with important cultural traits [p.113].

And they add:

> to discern a causal interaction between genes and culture is not to make a category mistake; indeed, its denial is a logical contradiction once culture is reckoned to the environment, cultural traits are reckoned to the phenotype, and the core conditional of evolutionary theory is understood just as before [p.113].

I believe that the authors have seriously overestimated the power of pure reflection here, and have tried unsuccessfully to turn an empirical, scientific issue into a philosophical one.

In one sense fortunately, and in another sense unfortunately, the authors' stimulating account of the ramifications of an adaptationist approach to human nature does not entirely depend upon their having established the all-importance of evolution by natural selection. It is fortunate in that their discussions, and many of their arguments, are still well worth consideration. It is, however, unfortunate in that the needless mistakes are distracting indeed. □

John Beatty is an Associate Professor of Philosophy at Arizona State University, Tempe, Arizona.

Paper crust

Princeton University Press have re-issued in paperback *The History of the Earth's Crust*, edited by Robert A. Phinney, the proceedings of a conference held in 1966 which proved to be a landmark in the earth sciences. The book was first published in 1968. Price of paperback is $11.50, £10.

Aspects of genius

R.S. Woolhouse

Leibniz. By G. MacDonald Ross.
Oxford University Press: 1984. Pp.121. Hbk £7.95, $12.95; pbk £1.95.

LEIBNIZ (1646–1716) was a multifaceted genius. He was archivist, diplomat, engineer, inventor, librarian, poet and politician. And his vast output of writing covered alchemy, anthropology, dynamics, economics, geology, history, jurisprudence, linguistics, logic, mathematics, numismatics, philosophy and religion.

The introduction to George MacDonald Ross's clear and very readable contribution to the *Past Masters* series prides itself on recognizing this fact. It leads us to expect the novelty of a discussion of all aspects of Leibniz's work and thought. But, after the initial notice taken of them in the valuable account of his life, most are ignored. As usual it is Leibniz's philosophy and parts of his mathematics that really receive the attention.

As even this is a lot to cover in a limited space it need be no surprise if this short book is not without flaws. Though Leibniz indeed says otherwise, it is not true of the historical Descartes that he squared human behaviour with his law of motion-conservation by making the soul change only the *direction* of motion of brain particles, not the *amount*. And though Leibniz did question how mind could possibly act on body, this was a background metaphysical worry. It was not a particular response to an attempt to make that action consistent with believed empirical laws. His specific objection to the manoeuvre he attributed to Descartes was that though it saved Descartes's (in fact false) law of motion-conservation, it did not save the (true, but unknown to Descartes) law of momentum-conservation.

Yet MacDonald Ross's achievement in introducing and summarizing Leibniz is considerable. Inevitably he compresses and omits. But he does not generally resort to superficialities, or rely on vague and general gestures. As a whole the book is fresh, stimulating and very informative. □

R.S. Woolhouse is Senior Lecturer in Philosophy at the University of York, and editor of Leibniz: Metaphysics and Philosophy of Science *(Oxford University Press, 1981).*

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF BIOCHEMISTRY

2 RESEARCH ASSISTANTS — 3 YEAR POSTS

Applications are invited for two 3 year posts of Research Assistant commencing salary £6,310 per annum, to contribute to an established line of research concerning Cellular Studies on the factors controlling the differentiation of bovine adipocyte precursors.

Applicants should have or expect to obtain in the near future a good degree in Biochemistry or a related discipline.

Applications (2 copies), together with the names and addresses of two referees should be forwarded to the Establishment Officer, University College, Cardiff, PO Box 78, Cardiff CF1 1XL. Closing date 5th July, 1984. Ref: 2791. (2250)A

UNIVERSITY OF ABERDEEN

DEPARTMENT OF MICROBIOLOGY

TEMPORARY LECTURESHIP

The Department of Microbiology invites applications for a temporary Lectureship for one year from October 1984. The post arises from the award of a Nuffield Research Fellowship to Dr I R Booth, and the successful applicant will be expected to assist with teaching in microbial physiology, genetics and molecular biology. There will be the opportunity also to carry through a research programme.

Salary within the range £7,190 to £8,530 per annum on Lecturers salary scale (under review).

Further particulars and application forms from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 15 June 1984. (2170)A

ENDOWED CHAIR PROFESSOR OF PHYSICS

The UCLA Physics Department has an open Endowed Chair position. An appointment will be considered in experimental and theoretical physics in any of the following fields: High and Intermediate Energy, Low Temperature, Condensed matter and Statistical Mechanics, Plasma and Astrophysics (theory only). The successful candidate will have a regular University of California tenured faculty position; the endowment income will support the candidate's program. The successful candidate will be expected to lead an internationally recognized research program, and to teach at the graduate and undergraduate level. Applicants should send a curriculum vitae, a brief statement of past, present and future research interests, and the names of 5-10 referees to C F Kennel, Chair Search Committee, Department of Physics, University of California, Los Angeles, CA 90024. The University of California is an affirmative action/equal opportunity employer. (NW590)A

UNIVERSITY OF LONDON

CHAIR OF MOLECULAR BIOLOGY

TENABLE AT THE INSTITUTE OF CANCER RESEARCH

The Senate invite applications for the above Chair. The Professor will be Chairman of the Section of Cell and Molecular Biology which is situated in the Chester Beatty Laboratories at Fulham in association with the Sections of Biology, Chemical Carcinogenesis and the Leukaemia Research Fund Centre. The Section has varied interests at this time, including cell and molecular biology of neoplasia and eukaryotic cell genetics.

Applications (11 copies) should be submitted to the Academic Registrar (N), University of London, Malet Street, London WC1E 7HU, from whom further details should first be obtained.

Closing date for receipt of applications: 20 July 1984. (2291)A

SQUIBB

R&D DIRECTOR
Japan

Squibb, a major international pharmaceutical company, currently is seeking candidates for the position of R&D Director in its Japanese affiliate with offices in Tokyo. The Director must provide strong intellectual and administrative leadership to a staff of about 50 scientists who have responsibility for the registration in Japan of new human ethical and animal health products. In meeting these responsibilities, the department monitors Japanese regulatory requirements, oversees preclinical and clinical studies conducted in Japan, and prepare the necessary registration documents. Throughout this process, close liaison is maintained with the central research laboratories in the United States.

The successful candidate will have at least 15 years experience in the health care field after receiving an MD or PhD degree (or equivalent) and must be fluent in both Japanese and English.

Interested candidates should send their current resume directly to: **Mrs. Anne V. Corey, International Personnel Director, Squibb Corporation, P.O. Box 4000, Princeton, NJ 08540.** An equal opportunity employer. (NW577)A

IMMUNEX CORPORATION is a multidisciplinary biotechnology company pursuing research and development of important diagnostic and immunoregulatory therapeutic products. An opening currently exists in its

HYBRIDOMA GROUP

for a person who has several years experience in tissue culture as well as extensive knowledge of all aspects of hybridoma technology; including cell fusion and screening assays. Applicants (B.S., M.S. or Ph.D.) must be able to work in a group setting and be highly motivated.

Please send a resume and the names of three references to:

Personnel Director
Immunex Corporation
51 University Street
Seattle, WA 98101 (NW587)A

immunex

CSIRO
AUSTRALIA
RESEARCH FELLOW
$A25,342-$A37,274
DIVISION OF WILDLIFE AND RANGELANDS RESEARCH
CANBERRA ACT

GENERAL: CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Wildlife and Rangelands Research is a member of the Institute of Biological Resources.

FIELD: Virology/Epidemiology.

GENERAL: CSIRO's Division of Wildlife and Rangelands Research undertakes research into the general principles underlying the control of animal and plant populations and the application of this knowledge to ecosystem mangement and conservation. One of the research teams at the Division's laboratories at Canberra has conducted long-term fundamental field and laboratory studies of the ecology, physiology and behaviour of the European rabbit over the past 25 years, and of its response to and interaction with myxoma virus.

Recent field experiments have shown that myxomatosis continues to control rabbits in agricultural regions. In the semi-arid inland of Australia however, rabbit numbers still fluctuate greatly over wide areas, and are largely unchecked by some outbreaks of myxomatosis which are spasmodic. Major questions are how and where does the myxoma virus survive between epidemics, what are the reasons for failure of some outbreaks to control rabbits, what threshold level of infection in the population facilities spread by vectors, and what limits the rate of spread of the virus on both sides of that threshold.

DUTIES: Initiate research into the epidemiology of myxomatosis in semi-arid and arid Australia under field conditions, seeking ways of improving the effectiveness of the disease. The Division has a new animal house with isolation facilities, and has a current but small study of techniques to identify myxoma field strains. The appointee will take charge of that study and integrate this work closely with ecological field studies.

QUALIFICATIONS: A PhD degree or equivalent qualifications and considerable research experience in virology and/or epidemiology.

TENURE: A term of 5 years with Australian Government superannuation benefits available.

APPLICATIONS: Stating full personal and professional details, the names of at least two referees and quoting reference No C8817, should be directed to:

The Acting Chief
CSIRO Division of Wildlife and Rangelands Research
PO Box 84
LYNEHAM ACT 2602
AUSTRALIA

By July 6, 1984.

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER

(W1029)A

King Saud University
(formerly University of Riyadh)
Riyadh, Saudi Arabia

The College of Pharmacy, King Saud University, has vacant faculty positions

PROFESSOR, ASSOCIATE PROFESSOR, ASSISTANT PROFESSOR

for PhD holders and/or holders of academic titles earned at accredited universities who would be employed on contract basis as of commencement of the academic year 1984-1985 which begns on August 11, 1984.

The language of instruction at the college is ENGLISH.

and the college has the following departments:
Pharmaceutical Chemistry — Pharmacology — Pharmaceutics — Pharmacognosy — Clinical Pharmacy.

Noteworthy benefits:
- Free return air tickets annually for faculty member and family.
- Furnished accommodation or housing and furnishing allowances.
- Monthly transport allowance.
- Relocation allowance.
- End-of-service gratuity.
- Free medical and dental care covering family.
- Contribution by University to tuition fees of non-Arabic-speaking children.

Interested academicians are kindly requested to send non-returnable photocopies of their academic diplolmas and specialized experience certificates together with their résumés (including lists of their publications and references) and written applications indicating the position applied for and the subjects the applicant is qualified to teach to the Dean of college (P.O. Box 2457, Riyadh). His/her address and telephone number (if available) should also be included so that he/she could be contacted if selected for interview.

(W1031)

ECOLOGY/ EVOLUTION/ BEHAVIOR
Yale University Department of Biology

Yale University's Department of Biology seeks applicants for an assistant professorship in ecology, evolution or behavior.

Candidates with research interests which span more than one of the areas mentioned above are especially desirable. Duties associated with this position include teaching of graduate and undergraduate students and management of a strong research program. **Send curriculum vitae, summary of past and present research, and the names of at least three referees to: Executive Secretary, Ecology/ Evolution/ Behavior Search Committee, Department of Biology, Yale University, P.O. Box 6666, New Haven, CT 06511. Deadline for acceptance of applications is December 15, 1984. Yale University is an Equal Opportunity/ Affirmative Action Employer.**

(NW589)A

Yale University

The European Molecular Biology Laboratory, a research institute situated in Heidelberg, West Germany, invites applicants for the following vacancy.

TECHNICAL ASSISTANT

The successful applicant will work in a group concerned with the cloning of mammalian genes. There will be a strong emphasis on DMA technology and microbiological techniques.

Appropriate training in the above mentioned fields is essential. It would also be desirable if the candidate had previously been introduced to working with computers and physical methods. A working knowledge of English or German is required; knowledge of a second language (English, French, German) is desirable.

An above average salary will be offered to the successful candidate. Certain allowances are payable in addition, depending on personal circumstances. An initial contract of 3 years' duration which can be renewed, will be offered.

Please write briefly for an application form, quoting reference no 84/ 26 to:

EMBL Personnel Section, Postfach 10.2209, D-6900 Heidelberg.

(W1024)A

HEWLETT PACKARD

Managers for advanced research programmes

In all areas of Computer Science

Up to £35,000+substantial benefits

We are searching for a number of key scientific trail blazers to direct major research projects at the new Hewlett-Packard Research Centre, Bristol.

The Hewlett-Packard commitment to technical excellence is acknowledged in world markets. It has achieved a prominent position through the calibre of its research effort in Palo Alto. In 1983, the company spent $493m on R&D, representing 10.5% of sales revenue.

A further, and highly significant, example of Hewlett-Packard's commitment to the future, is the establishment of a new Research Centre in Bristol. The rationale for this development, centres on the recognition that in Europe, there are areas of particular expertise, which, if brought to bear, will significantly contribute to Hewlett-Packard's long term corporate product objectives.

Our immediate task is to recruit a number of managers, to drive specific project teams in the following areas:

- ★ Communication Networks/Data Coding and Encryption.
- ★ Artificial Intelligence/Expert Systems.
- ★ Software Engineering — developing tools and methodologies.
- ★ Graphics.

For these critical roles we are looking for people of very high calibre. They will be acknowledged experts in their field and have the management skills to lead talented teams creating some of the future generation of Hewlett-Packard products. Clearly we will be asking for high academic achievement, together with a record of creativity and implementation of design concepts, which has led to the successful introduction of products into the market place.

The managers appointed will establish close working relationships with their opposite numbers in Palo Alto, Universities and with Hewlett-Packard operating companies in Europe. Communications between Bristol and Palo Alto will be close through regular visits and the introduction of a teleconferencing facility. The Bristol Laboratory will conduct both unique and complementary research to its counterpart in Palo Alto. It will grow to a total of some 300 people by 1987.

If you would like to explore these opportunities further, send your curriculum vitae in confidence to Geoffrey King, Managing Director of Cambridge Recruitment Consultants, who is advising Hewlett-Packard on these appointments, which are open to both men and women.

Cambridge Recruitment Consultants

1a Rose Crescent, Cambridge CB2 3LL. Telephone: 0223 311316.

(2301)A

Selly Oak Hospital

PRINCIPAL BIOCHEMIST

Applications are invited from graduate scientists with a Clinical Chemistry and/or Rheumatological Biochemistry background and with proven research ability for a Principal Biochemist post as Head of the newly established routine and research Rheumatological Biochemistry Section in the Biochemistry Department at Selly Oak Hospital. The person appointed would work in close co-operation with the Birmingham University Department of Rheumatology and it is anticipated he/she would receive an appropriate honorary university appointment.

Full particulars, and application forms, from Mr. P. Scott, Head of Biochemistry Department, Selly Oak Hospital, Birmingham B29 6JD. NHS Whitely Council conditions of service apply. Applications, including CV and names of 2 referees, to Mr. P. Scott by 19 June, 1984. (2248)A

SOUTH BIRMINGHAM Health Authority

PRODUCT MANAGER

DNA SEQUENCING

BIO-RAD LABORATORIES, a leading biotechnology company located in the San Francisco Bay Area, has as a result of our continuing growth an immediate opportunity for an experienced professional to work as a part of our marketing team in the Research Products Group. We are seeking a highly motivated individual with a commitment to excellence who is ready for the next challenging career step.

This position requires DNA sequencing experience and familiarity with computer analysis techniques. The successful candidate will be results oriented, a good communicator, have strong marketing potential, and be willing to travel. Position includes but does not emphasize lab work, along with multidiscipline project management responsibilities.

Bio-Rad offers a competitive compensation package including comprehensive benefits and relocation assistance. If you would like to be considered for this position, please submit your resume, including salary history, to Human Resources Dept. #167, BIO-RAD LABORATORIES, 2200 Wright Avenue, Richmond, CA 94804. An equal opportunity employer.

(NW591)A

BIO-RAD *Bio-Rad Laboratories*

THE UNIVERSITY OF SYDNEY

LECTURESHIP IN INORGANIC CHEMISTRY

School of Chemistry

(Reference No 20/03)

The Lecturer will participate in teaching at the elementary, advanced undergraduate, and postgraduate levels. The department has active research groups in organometallic chemistry, bio-inorganic chemistry, analytical and environmental chemistry, crystal structure analysis, vibrational spectroscopy, coordination dynamics and molecular electro-optics. Preference may be given to applicants whose research specialisation is in applications of spectroscopic methods to biological inorganic chemistry.

The appointment will commence in or after September 1984.

Salary range: $A24,353-$31,994 per annum (under review).

Appointments to lectureships are usually probationary for three years and the University reserves the right not to proceed with any appointment for financial or other reasons. The costs of travel to Sydney by the appointee may be paid by the University.

Applications, quoting reference no. and including curriculum vitae, lists of publications and names of three referees, to the Registrar, University of Sydney, NSW 2006, Australia, by 20 July 1984.

For further information contact Professor H C Freeman in the University. (Telex AA20056).

Further general information also available from Association of Commonwealth University (Appts), 36 Gordon Square, London WC1H OPF.

(W1033)A

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT IN MOLECULAR BIOLOGY

Applications are invited for a postdoctoral position to identify sequences in the β gene of E.coli RNA polymerases necessary for enzyme function. The work will involve the use of genetic and biochemical techniques, including DNA sequencing, to locate the sites of substitutions known to perturb RNA polymerase activity in vivo. It will lead to the generation of a structure-function map.

This Grade 1A MRC-supported position, tenable for three years, has a starting salary of £7,190 per annum including USS benefits.

Applicants should send a curriculum vitae and the names of two referees to Dr Robert E Glass, Department of Biochemistry, Queen's Medical Centre, Nottingham, NG7 2UH (Telephone 0602-700111 extension 3395) from whom further information may be obtained. (2258)A

KINGSTON POLYTECHNIC

Faculty of Science

DEPARTMENT OF GEOLOGY

LECTURERII/SENIOR LECTURER IN GEOLOGY

(Ref: GG2)

2 posts:

Petrology/Geochemistry

Sedimentology)

Applications are invited for two posts which are available from 1st September. Applicants should have a high research potential and a strong interest in teaching. Preference will be given to candidates with experience in petrology/geochemistry and sedimentology, particularly of carbonate rocks. The successful candidates will be expected to take a lead in the research work of the Department and a willingness to make industrial contacts with a view to developing consultancy will be encouraged.

DEPARTMENT OF MATHEMATICS

LECTURER II/SENIOR LECTURER IN STATISTICS

(Ref: MA1)

Applications are invited for the above post, available from 1st September. Preference will be given to candidates with a postgraduate qualification in Statistics and/or industrial or consultancy experience. Recent involvement in Statistical Modelling or Optimisation would be an additional advantage.

Salary range Lecturer II/Senior Lecturer: £7860-£14,088 (under review) inclusive of London allowance. Please quote reference when applying.

Further details and application forms (to be returned by 29th June) from Personnel Officer, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. Tel 01-549 1366 ext 287. (2283)A

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF BIOCHEMISTRY

WELLCOME LECTURER

Applications are invited for the above post made available to the Department of Biochemistry by the Wellcome Trust. The appointment will be for three years in the first instance renewable for a further two years subject to satisfactory review. Salary will be in the range £7,190-£14,125 pa (under review).

Candidates, who should be under the age of 35, should have relevant experience in nucleic acid biochemistry. it is envisaged that the successful candidate will join a nucleus of staff interested in aspects of toxicology.

Applications (3 copies), the names of at least two referees together with a 500-word summary of proposed research should be forwarded to the Vice-Principal (Administration) and Registrar, University College, PO Box 78, Cardiff CF1 1XL, from whom further particulars may be obtained. Closing date 31st August, 1984. Ref: 2789 (2249)A

THE ROYAL VETERINARY COLLEGE
University of London

Division of Preclinical Studies

DEPARTMENT OF PHYSIOLOGY, BIOCHEMISTRY AND PHARMACOLOGY

TEMPORARY LECTURER IN VETERINARY PHARMACOLOGY

Applications are invited for a one-year temporary lectureship funded by the Wellcome Trust and available from 1 October 1984, or soon thereafter. Teaching duties will be on the preclinical veterinary pharmacology course. Applicants will be encouraged to pursue research work with Dr P M Headley on the actions of analgesic agents in vivo and in vitro.

Candidates should be postdoctoral and have experience of neurophysiological and neuropharmacological techniques. Ideally they will also have some experience of veterinary practice and/or teaching. Salary on the Lecturer scale up to £11,061 pa, including London Allowance. Salary will be determined by qualifications and experience.

Application form available from the Assistant Secretary (Personnel) The Royal Veterinary College, Royal College Street, London NW1 0TU (Tel: 01-387 2898 ext 230).

Prospective applicants should contact Dr P M Headley as soon as possible. Closing date 8 July 1984.
(2280)A

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF OCEANOGRAPHY

Applications are invited for the post of

POSTDOCTORAL SENIOR RESEARCH ASSISTANT

Assistant in the Department of Oceanography.

This post is funded under the NERC Estuarine Processes Special Topic Programme for a three year period beginning 1 October, 1984. The project is for work with Dr M R Preston in collaboration with Dr R F C Mantoura (Institute for Marine Environmental Research, Plymouth) on comparative studies of some organic traces in estuarine particulates. Candidates should preferably have experience of GC and HPLC techniques and should be prepared to divide their time approximately equally between the Liverpool and Plymouth Laboratories. Informal enquiries may be made to Dr M R Preston, tel: 051-709 6022 ext 2699.

Initial salary will be £7,190 per annum.

Applications, together with the names of three referees, should be received not later than 25 June, 1984 by The Registrar, The University, PO Box 147, Liverpool, L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/531/N.
(2231)A

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

DEPARTMENT OF MOLECULAR ENDOCRINOLOGY

Applications are invited from suitably qualified candidates for appointment as Lecturer within the Department of Molecular Endocrinology. The successful candidate will be primarily responsible for the day-to-day scientific and organisational management of a monoclonal antibody production unit forming part of the Supra-regional Assay Service (Hormones) Laboratory.

The post requires considerable experience and proven ability in hybridoma technology, the capacity to independently pursue effective methodological development in this field and an aptitude for teaching at a variety of undergraduate and post-graduate levels.

The successful candidate will also be encouraged to collaborate in studies on the development of the foetal central nervous system involving monoclonal antibody-based cell recognition techniques. Experience in this area, though advantageous, is not essential.

The salary will be within the Lecturer's scale and will be set at a point within the range commensurate with the responsibilities attachng to this appointment, and in accordance with age, qualifications and experience of the successful candidate.

Applications should be submitted to Professor Roger Ekins, Department of Molecular Endocrinology, The Middlesex Hospital Medical School, Mortimer Street, London W1N 8AA, together with the names of two referees, by 28 June, 1984.
(2292)A

BLOOMSBURY HEALTH Authority, Hospital for Tropical Diseases, London, England. Consultant Parasitologist. (Whole time/maximum part time). Applications are invited for the post of whole time/maximum part time Consultant Parasitologist. The successful candidate, who must be medically qualified, will be head of the Department of Parasitology providing a specialist diagnostic service. Close links exist with the London School of Hygiene and Tropical Medicine and it is anticipated that the postholder will have a fairly high academic commitment with appropriate honorary status. Those unable for personal reasons to work full time will be eligible to be considered for the post. Informal enquiries may be made by telephoning Dr M F R Waters, The Hospital for Tropical Diseases 01-387 4411. Application forms and job description available from the Medical Personnel Department, Bloomsbury Health Authority, 25 Grafton Way, London WC1E 6DB, or telephone 01-387 7643 (24 hour service) quoting reference PK/11. The closing date for receipt of applications is 24th August, 1984. Overseas candidates are invited to cable their intention of applying and send a curriculum vitae direct. An equal opportunities employer. (2238)A

CSIRO
AUSTRALIA

RESEARCH FELLOW — PLANT MOLECULAR BIOLOGY

$A25,342-$A37,274

DIVISION OF HORTICULTURAL RESEARCH
ADELAIDE SA

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Horticultural Research is a member of the Institute of Biological Resources.

FIELD: Nuclear/chloroplast interactions.

GENERAL: The aim of the Division's research is the improvement of woody perennial horticultural crops in Australia. These include a range of deciduous and evergreen species. Emphasis is placed upon the development of new techniques for the selection and breeding of improved plant type and on understanding the complex interaction between plant performance and the environment. The Division undertakes applied and basic research on a range of perennial horticultural plants (deciduous and evergreen) from both temperate and sub-tropical regions.

Intending applicants from UK and Europe may wish to make arrangements to talk to a member of the group who will be in Europe in July 1984.

LOCATION: The Division has laboratories at Adelaide, South Australia (Headquarters) and Merbein, Victoria. The appointee will be located at Adelaide.

DUTIES: As a member of a small team involved in studying the interaction of the nucleus and chloroplast in higher plants, the appointee will investigate the nature of the sequence homology between chloroplast and nuclear DNA.

QUALIFICATIONS: A PhD degree or equivalent qualifications in an appropriate field, (such as biochemistry, plant physiology or biology). Experience within the field of biochemistry of nucleic acids, including recombinant DNA technology and DNA sequencing, would be an advantage.

TENURE: A term of three years, commencing in 1984. Australian Government superannuation benefits are available.

APPLICATIONS: Stating full personal and professional details, the names of at least two professional referees, and quoting reference No A0881, should be directed to:

The Chief
CSIRO Division of Horticultural Research
GPO Box 350
ADELAIDE SA 5001
AUSTRALIA

By July 6, 1984.

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER (W1028)A

AFRC ANIMAL BREEDING RESEARCH ORGANISATION

Positions in Molecular Biology and Cell Culture

ABRO is currently seeking staff to join its newly-founded molecular biology group in Edinburgh. Research objectives are to investigate the potential of new techniques for genome manipulation of higher animals. During an initial period, research is expected to concentrate upon gene transfer into tissue culture cells and experience in genetic manipulation and/or mammalian cell culture would be advantageous.

Scientists with experience of DNA cloning in plasmids, cosmids and phages, sequencing, or DNA introduction into tissue culture cells by micro-injection or transfection are especially invited to apply.

Candidates should possess a good honours degree in molecular biology, biochemistry or a related subject. For appointment at the Higher Scientific Officer level a minimum of two years relevant post-graduate training or experience is expected. Candidates for recruitment at the Senior Scientific Officer level should have at least 4 years relevant post graduate research experience and will normally be expected to possess a PhD or equivalent qualification. Salaries will be according to qualifications and experience on the scales £7,149—£9,561 (HSO) and £8,970—£11,476 (SSO).

Applicants should submit a full curriculum vitae together with the names of two referees to:
The Secretary, Animal Breeding Research Organisation, West Mains Road, Edinburgh EH9 3JQ.

The Agricultural and Food Research Council is an Equal Opportunities Employer. (2264)A

CSIRO
AUSTRALIA
RESEARCH FELLOW/ SENIOR RESEARCH FELLOW DYNAMICAL METEOROLOGIST
$A25,342-$A37,274
DIVISION OF ATMOSPHERIC RESEARCH
MORDIALLOC VIC

GENERAL: CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Atmosphereic Research is of member of the Institute of Physical Sciences.

The Division of Atmospheric Research maintains broadly-based research programs in dynamical meteorology, boundary layer physics, climatology, radiation, cloud physics and atmospheric chemistry. Total staff numbers approximate 130.

The Division's Large Scale Dynamics program is concerned with the study of processes which determine the general circulation of the atmosphere on length scales of 1000 km and greater together with its variability and the climatic consequences of this variability.

DUTIES: To undertake research into the observational analysis and diagnostic aspects of the program and, in collaboration with other members of the group, to contribute to related theoretical and modelling studies of the atmosphere.

QUALIFICATIONS: A PhD degree or equivalent qualifications in the physical sciences with demonstrated research ability and experience in dynamical meteorology. Experience in the analysis and interpretation of atmospheric data is highly desirable.

TENURE: A term of 3 years with the possibility of a further 2 year term. Australian Government superannuation benefits available.

APPLICATIONS: Stating full personal and professional details, the names of at least two referees and quoting reference No A1848, should be directed to:

The Chief
CSIRO Division of Atmospheric Research
Private Bag No 1
MORDIALLOC VIC 3195
AUSTRALIA

By July 6, 1984.

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER

(W1030)A

IMMUNOLOGICAL/ MICROBIOLOGICAL RESEARCH
FACULTY OF DENTISTRY — THE UNIVERSITY OF ALBERTA

Applications are invited for a full-time position as a Research Scholar in Immunology and/or Microbiology. The successful candidate must have a research degree in Immunology or Microbiology with an interest in immunochemistry and bacterial ecology related to periodontal diseases. Research will be directed toward characterisation of the interaction of surface components of oral bacteria with secretory antibodies and other secretory glycoproteins and also with serum antibodies. These positions will be dependent upon successful application for a competitive award by an external granting agency. Appointment as Scholar will be on a long-term basis and will enjoy the privileges of the University academic rank at which the appointment is made (Assistant Professor, Associate Professor or Professor level presently $29,720-$41,820; $37,420-$53,658 and from $48,010). The University of Alberta is an equal opportunity employer but in accordance with Canadian immigration requirements this advertisement is directed to Canadian citizens and permanent residents of Canada. **Interested applicants should forward their curriculum vitae, outlines of their research experience and names of three referees to Dr J A Hargreaves, Director of Graduate Studies and Research, Faculty of Dentistry, The University of Alberta, Edmonton, Alberta T6G 2N8. The closing date for applications is July 1, 1984.** (NW583)A

THE UNIVERSITY OF SHEFFIELD
DEPARTMENT OF PHYSICS
RESEARCH ASSISTANT
AMORPHOUS SEMICONDUCTORS AND DISORDERED SUPERLATTICES

Applications are invited from men and women for the above post funded by SERC, to join an established group intrested in the optical and electronic properties of disordered semiconductors. Systems of particular interest include amorphous silicon, amorphous Si-SiN quantum wells and crystalline GaAs-GaA1As superlattices. Involves the development of novel two beam luminescence techniques, photon deflection spectroscopy for the measurement of weak absorption processes, and the use of a dye laser to measure excitation spectra. Tenable for three years.

Initial salary £7,190-£7,630 a year on Range 1A.

Enquiries to Dr T M Searle/ Professor I G Austin, Department of Physics, the University, Sheffield S3 7RH to whom applications, with the names of two referees, should be sent as soon as possible. Please quote ref R94/g (2253)A

POSTDOCTORAL POSITION available immediately to study 3-dimensional architecture of chromosomes using optical and electron microscopy and computerized, 3-dimensional reconstruction schemes. The candidate should have strong background in computer science/computer graphics and/or macro-molecular crystallographic experience. Send resume with names of 3 references to: Drs David A Agard or John W Sedat, Department of Biochemistry & Biophysics, University of California, San Francisco, California, USA. (NW578)

UNIVERSITY COLLEGE LONDON
COMPUTER PROGRAMMER

Computer programmer with an interest in the nervous system is required to work in a programme on the anatomy and physiology of the visual system in a well equipped laboratory. The successful applicant will be expected to manage the computer systems, maintain existing programmes and develop software to aid research. Programming in several areas, including image processing, graphics and data acquisition is involved. Experience of RSX-IIM, FORTRAN, MACRO-LL, BASIC and 6502 assembler would be an advantage.

Applications, giving the names of two referees, to Professor S Zeki, Department of Anatomy & Embryology, University College London, Gower Street, London WC1E 6BT. (2267)A

WEST VIRGINIA UNIVERSITY
invites applications and nominations for the position of

DEAN OF THE COLLEGE OF OF AGRICULTURE AND FORESTRY AND DIRECTOR OF THE AGRICULTURAL AND FORESTRY EXPERIMENT STATION

The Dean is responsible for all educational, research, extension and service programs of the College and Experiment Station. Qualifications include an earned doctorate, a record of academic and research excellence, a firm commitment to the mission of a comprehensive land grant university and ability to communicate effectively with faculty, staff, students and representatives of commodity groups. Demonstrated administrative leadership is desired.

Applications including a résumé, other supporting material and names of three references will be accepted until July 15, 1984. Nominations and applications should be addressed to: Chairman of Search Committee, School of Dentistry, Medical Center, West Virginia University, PO Box 6305, Morgantown, West Virginia 26506-6305.

West Virginia University is an Affirmative Action, Equal Opportunity Employer. (NW497)A

POSTDOCTORAL POSITIONS (two) available in a leading research group. One for studying mutations in genes for collagens in human genetic diseases, and the other studying gene expressions during mouse embryogenesis. Background in molecular biology helpful but not essential. Interested candidates should send a letter describing research experience with a curriculum vitae and three letters of recommendation to: D J Prockop, MD, PhD, Department of Biochemistry, University of Medicine and Dentistry of New Jersey — Rutgers Medical School, PO Box 101, Piscataway, New Jersey 08854. An Equal Opportunity/Affirmative Action Employer. (NW582)A

THE UNIVERSITY OF SHEFFIELD
POSTDOCTORAL NEUROANATOMIST

Applications are invited from me and women for a

POSTDOCTORAL POSITIOI

funded by the SERC, tenable for fixed term until 15 May 1987 t investigate efferent projections of th superior colliculus. Experience wit neuroanatomical tract tracin techniques essential. The proje offers the opportunity to combi anatomical analysis with behaviour and neuropharmacological tec niques. Initial salary £7190 a year Range IA. Details from Dr Redgrave (0742 78555 ext 6556 Applications, including the names three referees, to the Registrar a Secretary (Staffing), The Universit Sheffield S10 2TN as soon possible. Quote ref: R91/G. (2235)A

Southampton THE UNIVERSITY

NEW BLOOD LECTURESHIP IN GEOLOGY

(Re-advertisement)

Applications are invited for the post of Lecturer in Geology with special emphasis on the geochemistry of fluid-rock interactions as applied to metals and/or hydrocarbons. Applicants with interests in fields such as hydrothermal alteration, petroleum generation and migration, diagenesis, pore fluids, fluid inclusions or stable isotopes will be particularly welcome. This new blood post is intended to reinforce the research interests of the Department in applied geology.

Salary scale: £7,190 × £450 (15) £14,125 per annum (under review). The initial salary will depend on qualifications and experience.

Further particulars may be obtained from Mr D A S Copland, The University, Southampton, SO9 5NH to whom applications (7 copies from United Kingdom applicants should be sent not later than 2 July 1984, quoting reference No. 2039. (2277)A

Senior Positions in Biochemistry and Nerve Cell Biology

The Sandoz Institute for Medical Research invites applications for the positions of Head of Laboratory (one in Biochemistry and one in Cell Biology & Cell Culture) tenable from 1 January 1985.

The Institute will be housed in well-equipped and spacious new laboratory accommodation which is being built within the precincts of University College London, with which strong academic links will be forged. The scientific staff will be up to 25–30 by 1987.

The Institute will embark on a programme of basic research in neurobiology, concentrating initially on mechanisms involved in nociception, with the long-term aim of developing new compounds of potential therapeutic value. Initially there will be six laboratory groups (Medicinal Chemistry, Biochemistry, Neuropharmacology, Cell Biology and Cell Culture, Immunology, Cellular Electrophysiology) which will collaborate on a range of individual projects.

Applicants for both positions need to have proven ability to organize and supervise the running of a research laboratory, and to contribute original ideas to a multidisciplinary research effort. Enthusiasm for interdisciplinary collaboration is essential.

Candidates for the Biochemistry position should have experience in the field of receptor-regulated mechanisms and/or the isolation and characterization of membrane proteins.

Candidates for the Cell Biology position should have general experience in cellular neurobiology and neuronal cell culture techniques, preferably with an interest in the biology of sensory neurons.

Salary negotiable, plus comprehensive benefit package including car. Assistance with relocation if required.

Applications by 16 July 1984, including cv and names of three referees, to Professor H.P. Rang, FRS, Director, Sandoz Institute for Medical Research, Department of Pharmacology, University College London, Gower Street, London WC1E 6BT (Telephone 01-388 5314), from whom further information can be obtained.

SANDOZ

(2302)A

THE UNIVERSITY OF MELBOURNE

RESEARCH FELLOW GRADE 1 (EXTENDIBLE TENURE)

in the

DEPARTMENT OF BIOCHEMISTRY

Applications are invited from people with a background in physical chemistry or physical biochemistry for appointment as Research Fellow 1. The work involves the use of photophysical techniques to characterize the dynamics of cytoskeletal networks and to study proximity relationships in biomembranes. The position is sponsored by the Australian Research Grants Scheme and is for 2 years.

Salary up to $A22,213 per annum and in the range of $A20,991 to $A24,047. For further information please contact Dr W H Sawyer, Department of Biochemistry, University of Melbourne, Parkville 3052, Victoria, Australia.

Further printed information regarding details of application procedure and conditions of appointment is available from the Appointments Officer (Academic), University of Melbourne, or from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF.

Applications close on 15 August 1984.

(W1035)A

SCOTTISH CROP RESEARCH INSTITUTE

Invergowrie, Dundee DD2 5DA
Tel: Invergowrie 731
(STD code 082 67)

SCIENTIFIC OFFICER/ HIGHER SCIENTIFIC OFFICER

The Zoology Department requires an SO/HSO to undertake research on mechanisms of plant resistance to insect pests of forage brassicas and soft fruit. The appointee will work closely with plant breeders to examine factors conferring resistance amongst a range of plant breeding material.

Qualifications: A first or upper second class honours degree in an appropriate subject and at least two years' relevant post-qualifying experience which could be in the entomology and/or plant chemistry and may be a course of research and study leading to a PhD degree for appointment to the higher grade.

Salary: SO — £5,682-£7,765, HSO — £7,149-£9,561. Non-contributory superannuation.

The Institute is an equal opportunities employer.

Applications giving full details of age, qualifications and experience together with the names of two referees should be lodged by 9 July, with Mrs J A Shepherd, the Personnel Officer of the Institute, from whom further particulars may also be obtained. (2256)A

BTL

"BUILDING A BIOTECHNOLOGY BUSINESS"

Positions in Environmental and Agricultural Biotechnology

BioTechnica Limited (BTL), a new British biotechnology company affiliated with BioTechnica International Inc. of Cambridge, Massachusetts, seeks scientists for the following positions:

1. **Senior Scientist — Programme Manager for the Pollution Group:** to work on the development of microbial systems for aerobic biodegradation, particularly aqueous treatment systems and decontamination of polluted land. The successful applicant will lead this group and will be concerned both with research and with the development of new products. It is anticipated that candidates will hold a Ph.D. and have had several years post-doctoral experience, probably in industry.

2. **Assistant Scientist:** to work on the growth and downstream processing of microbial products for agriculture. Candidates should preferably hold a good honours degree (or higher degree) in microbiology with a major interest in microbial physiology or fermentation technology.

3. **Research Technician:** to assist the development of micro-organisms for use in agriculture. Candidates should preferably hold a degree in microbiology or have substantial experience in basic microbial culture techniques.

4. **Biochemical Engineer:** To design novel systems for environmental biotechnology. Candidates should preferably hold an M.Sc. degree.

Competitive salaries will be paid and participation in a staff share option scheme is available.

Applications in writing by sending a full CV together with the names of three referees to:

Miss M. Ghosh, Office Manager, BioTechnica Limited, 5, Chiltern Close, Cardiff CF45DL, Wales, U.K. (2266)A

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF PATHOLOGY

PARASITE IMMUNOLOGY PROGRAMME MOLECULAR BIOLOGIST

Position immediately available for a postdoctoral scientist up to 32 years old to work on an EEC-supported project until March 1986, with a possibility of further extension.

This new project in the field of onchocerciasis (river blindness) has recently been initiated in a group with a strong background in the immunology and molecular biology of schistosomiasis. Applications are invited from scientists with experience in molecular biology to work on the molecular cloning of DNA encoding antigens of *Onchocerca volvulus* that may be of importance in immunopathology, immunoprohylaxis and immunodiagnosis, and to participate in ongoing studies on schistosomiasis. The project involves close collaborative work with the Institut Pastuer, Lille, and with the MRC Laboratory, Bo, Sierra Leone.

Previous experience in parasitology not required. Salary range University Scale £8,080 to £10,710, depending on age.

Informal enquiries to Dr. A. E. Butterworth or Dr. D. W. Taylor (0223 353492). Formal applications, with curriculum vitae and names of two referees, to Mr. P. Wilburn, Department of Pathology, Tennis Court Road, Cambridge CB2 1QP (0223 64631).

(2233)A

MARIE CURIE MEMORIAL FOUNDATION RESEARCH INSTITUTE

Two Post-doctoral positions in Molecular Biology. The first will involve the application of recombinant DNA technology to the study of cellular gene activation by transforming proteins.

The second will investigate the role of the transformation — associated protein p53 in cell proliferation and transformation. Eukaryotic vectors expressing p53 and a variety of mutants are available for this work.

These three-year appointments are available now and salary will be on the Lecturer Scale.

Apply with C.V. and the names of two referees to Dr. G. Currie, Marie Curi Research Institute, The Chart, Oxted, Surrey (088388-3055). (2163)A

MOLECULAR EVOLUTION/ SYSTEMATICS
Yale University Department of Biology

Yale University's Department of Biology seeks applicants for an assistant professorship in molecular evolution and/or molecular systematics.
Candidates expertise should include both the use of modern DNA technology to investigate either eucaryotic or procaryotic systems and a knowledge of the theory and analytical methods directed toward the study of evolution. Duties associated with this position include teaching of graduate and undergraduate students and management of a strong research program. The appointment will take effect no sooner than July 1, 1985.
Send curriculum vitae, summary of past and present research, and the names of at least three referees to: Executive Secretary, Molecular Evolution Search Committee, Department of Biology, Yale University, P.O. Box 6666, New Haven, CT 06511. Deadline for acceptance of applications is December 15, 1984. Yale University is an Equal Opportunity/ Affirmative Action Employer. (NW588)A

Yale University

WELSH NATIONAL SCHOOL OF MEDICINE
(University of Wales)

DEPARTMENT OF MEDICAL BIOCHEMISTRY

POST-DOCTORAL RESEARCH OFFICER

Applications are invited for the above post in which the successful candidate will apply a group of monoclonal antibodies to the investigation of the clinical significance and molecular biology of complement component C9. The post will be for 3 years and is funded by the Medical Research Council.

Candidates should have, or have submitted, a PhD thesis in biochemistry, immunology or a related discipline. The successful candidate will be working in an active research team headed by Dr A K Campbell engaged in elucidating molecular mechanisms underlying issue injury in immune based disease.

Salary on the scale for University Research and Analogous Staff Grade 1A with commencing salary up to £8,080 for suitably qualified candidates.

Further details from the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff, CF4 4XN (Tel No 0222/755944 Ext 2296) (quoting Ref No C38/4/49) to whom applications in the form of a curriculum vitae with the names and addresses of two referees should be submitted by 6th July, 1984.

(2246)A

THE UNIVERSITY OF MELBOURNE

LECTURER (CONTINUING) in the

DEPARTMENT OF PHYSICAL CHEMISTRY

A vacancy exists in the Department of Physical Chemistry for a continuing appointment at Lecturer level, of a suitably qualified physical chemist. The Department has major research and postgraduate education commitments in areas of colloid and surface chemistry, ultra-fast spectroscopy, photochemistry and electrochemistry. The new appointee would be expected to develop a research programme in one or more of these areas. Opportunity exists to participate in a range of research liaison programmes with other Departments of the University and with CSIRO and the chemical industry.

Salary in the range $A24,353 -$A31,994 per annum. For further information please contact Dr A A Humffray, Chairman of Physical Chemistry, in the University.

Further printed information regarding details of application procedure and conditions of appointment is available from the Appointments Officer (Academic), University of Melbourne, Parkville, Victoria 3052, Australia, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF.

Applications close 30 July 1984.

(W1036)A

THE UNIVERSITY OF LEEDS

DEPARTMENT OF PHYSICS

LECTURER

Applications are invited for the above post in experimental condensed matter physics established under the "New Blood" scheme. The successful applicant will be expected to join the group concerned with experimental and theoretical aspects of metallic glasses, where recent studies have been mainly on their thermal, magnetic, and transport properties. While the appointee will primarily be concerned with the physics of amorphous materials an interest in either new methods of preparation or measurements at millikelvin temperatures would be an advantage.

The age limit for these posts is 35.

Salary on the academic scale for lecturers (£7190-£14125) (under review) according to age, qualifications and experience.

Application forms and further particulars may be obtained from The Registrar, The University, Leeds LS2 9JT, quoting reference number 52/29/D. Closing date for applications 15 June 1984. (2251)A

MANAGER: PROJECT DEVELOPMENT

A position is available in the corporate development program of a US agricultural company. Qualifications are:

1. PhD in Agronomy, Horticulture or related field.

2. Familiar with new technologies in plant genetic engineering, tissue culture and cell biology.

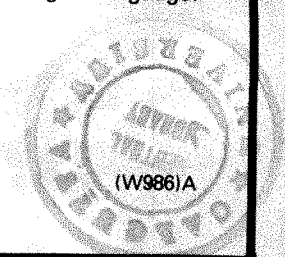
3. Familiar with general agricultural business, seeds and plants.

4. Person with interest in marketing preferred.

Send resume to: Dr Irwin Y E Chu, Corporate Vice President, Research & Development, George J Ball, Inc, PO Box 335, West Chicago, IL 60185 USA. (NW585)A

THE UNIVERSITY OF SHEFFIELD

TEMPORARY LECTURESHIP IN PSYCHOLOGY



Applications are invited from men and women for the above post, tenable for a fixed term of 3 years from 1st october 1984. The person appointed will have a major responsibility for the teaching of AI and cognition to undergraduates, including the supervision of final year projects using POP 11. Salary scale £7,190-£14,125 a year. Particulars from the Registrar and Secretary (Staffing), The University, Sheffield, S10 2TN, to whom applications (5 copies) including the names and addresses of 3 referees should be sent by 25th June 1984, quoting ref: R97/G. (2236)A

KINGDOM OF SAUDI ARABIA
KING SAUD UNIVERSITY
COLLEGE OF AGRICULTURE
RIYADH, SAUDI ARABIA

Qualified personnel are invited to apply for the following posts of FACULTY MEMBERS (Professors, Associate Professors, Assistant Professors), LECTURERS, DEMONSTRATORS, RESEARCH ASSISTANTS and TECHNICIANS for the academic year 1984 - 1985.

Department	Specialization	Qualification
I. Staff members:		
(1) Food Science	a. Human nutrition metabolism. b. Dairy technology. c. Food analysis.	Ph.D., Teaching experience, Arabic speaking.
(2) Animal Science	a. Poultry nutrition.	-do-
(3) Plant Production	a. Cytogenetics.	-do-
(4) Ag. Economics & Rural Sociology	a. Farm management. b. Marketing of agricultural products.	Ph.D., Teaching experience, Associate or Professors only, Arabic speaking.
(5) Home Economics & Nutrition (Female only)	a. Textiles and costumes.	Ph.D., Teaching experience, Arabic speaking.
II. Lecturers:		
(1) Home Economics and Nutrition (Female only)	a. Plant production (ornamentals) b. Plant production (field crops).	M.Sc., Teaching experience, Arabic speaking.
(2) Plant Production	a. Plant production (vegetable crops).	-do-
(3) Animal Production	a. Animal production	-do-
III. Demonstrators:		
(1) Food Science	a. Fish and meat technology. b. Food microbiology. c. Food analysis.	B.Sc. "B" average or higher, past experience in teaching, research is preferred, Arabic speaking.
(2) Plant Production	a. Horticulture (vegetable crops).	-do-
(3) Agricultural Engineering	a. Agric. Engineering.	-do-
IV. Research Assistants:	a. Food microbiology. b. Food chemistry and analysis. c. Horticulture (Pomology). d. Field Crops (Breeding).	Preferably M.Sc. with research experience in the field of specialization.
V. Technicians:	a. Human nutrition. b. Cereal technology. c. Analytical chemistry in the field of food science.	Experience in field of work, conducting and operating laboratory equipment. Experience and training in operating food and nutrition analyses equipment preferably IR, AAA, AA, GLC, HPLC. Good knowledge of English language.

Please apply to:
Dean, College of Agriculture,
King Saud University,
P.O. Box 2460,
Riyadh 11451,
Kingdom of Saudi Arabia.

Opportunities in Pharmaceutical Development

Pathology Division *Ware, Herts*

Glaxo Group Research is Britain's leading pharmaceutical research organisation, with a distinguished reputation for developing safe and effective medicines. Due to an expanding workload, two positions have arisen in our Pathology Division.

Cytogeneticist

We require a good honours graduate to join our team of Genetic Toxicologists. You will be involved in cytogenetic analysis including metaphase chromosome studies of mammalian cells. You will be expected to assist in the preparation of the specimens for analysis and in the assessment of results. The laboratories are purpose built to the highest standard and equipped with the latest computer technology.

Applications are invited from graduate cytogeneticists with some experience of metaphase analysis.

Reproductive Toxicologist

We require a graduate to be a study supervisor in our Toxicology Department working in the team assessing the safety of new drugs when used in pregnancy.

You will be involved in the implementation of reproductive toxicology studies and ensuring the correct execution of the studies according to GLP requirements.

You will be expected to be fully aware of the status of each study, as it proceeds, by collating and correlating data generated by the department's dedicated computer system.

Candidates should possess a relevant good honours degree together with a sound knowledge of animal anatomy. Experience gained in this field of work would be a distinct advantage.

We offer a competitive salary in the range £6,175-£10,770. Your starting salary will reflect your experience. Other benefits of a highly successful company include participation in Glaxo Group profitability, non-contributory pension scheme, an active sports and social club and, where appropriate, assistance with relocation to this pleasant area of Hertfordshire.

Please write or telephone for an application form, stating which vacancy interests you to: Mr. D. Latter, Personnel Officer, Glaxo Group Research Ltd., Ware, Herts. SG12 0DJ. Tel: Ware (0920) 3993.

Glaxo *Group Research Ltd.*

(1954)A

University College of Swansea

Part-Time Teaching Assistant

Applications are invited for the vacancy of **Part-time Teaching Assistant** in the **Department of Zoology.** Applicants should have a Ph.D. degree and a research interest in the cellular effect of heavy metals on fish reproductive systems.

The appointment, which will be for one year from October 1, 1984, will be on a scale up to £4,265 per annum.

Further particulars and application forms (2 copies) may be obtained from the Registrar, University College of Swansea, Singelton Park, Swansea SA2 8PP, to which office they should be returned by Friday, June 29, 1984. (2278)A

POSTDOCTORAL FELLOW/ASSISTANT PROFESSOR (PhD or MD) in molecular biology to join basic gastrointestinal research laboratory. Applicant should have strong background in molecular biology. Candidate will join group with ongoing interest in malignant transformation, intestinal cell function and transport, molecular biology involving viral hepatitis and hepatoma, and studies of oncogenes in gastrointestinal malignancy. Individual will be encouraged to conduct independent research but will be expected to participate in collaborative projects. Send curriculum vitae, bibliography, references, and statement of research interests to: Dr Kurt J Isselbacher, Chief, Gastrointestinal Unit, Massachusetts General Hospital, Boston, MA 02114. An Equal Opportunity Employer.

Research Scientist, Earth Structure Studies

Energy, Mines and Resources
Earth Physics Branch
Ottawa, Ontario

We require a geophysicist/geologist to conduct field investigations and research studies into the nature and structure of major geological features throughout the Canadian landmass. Emphasis will be on the application of deep seismic reflection techniques, including vibrosesis, and regional three-dimensional seismic refraction methods. Other geological and geophysical methods will be incorporated as necessary. Field investigations will be carried out in all parts of Canada, from the east and west coasts to the Arctic Ocean Basin. Research studies will demand extensive use of state-of-the-art computer-based processing and international methods.

You require graduation with a doctorate degree from a recognized university in geophysics, geology, physics or a related field, or a lesser degree with evidence of research experience and productivity equivalent to that of a doctorate degree. Extensive experience in the processing and interpretation of multifold seismic reflection data is also required. Knowledge of either English or French is essential.

We offer a salary ranging from $26,834 to $49,913 commensurate with your qualifications and experience. Effective 23 June 1984, the revised salary range will be $28,176 to $52,409.

Forward your application form and/or résumé, quoting reference number S-84-31-5523-JG47(G26), to:
Joan Girling (613) 593-5331
Public Service Commission of Canada
Ottawa, Ontario K1A 0M7

Closing date: 31 August 1984 (NW592)A

The Public Service of Canada is an equal opportunity employer Canada

---

POSTDOCTORAL RESEARCH POSITION: Available immediately for recent PhD or MD with a strong background in molecular biology/genetics of animal viruses. Candidates with excellent academic records, some experience in DNA technologies including cloning and a strong interest in tumor virology will be given preference. Please send résumé, abstract of the thesis along with other evidence of scholarly productivity, and the name and telephone numbers of three referees to: Nurul H Sarkar, PhD, Memorial Sloan-Kettering Cancer Center, 1275 York Avenue, NY 10021, USA. (NW541)A

POSTDOCTORAL POSITION: protein chemistry and/or immunochemistry background. This person will provide the biochemical expertise for a small team developing synthetic membrane bound ion-channel receptors. Experience with cross-linking or affinity labelling and lipid membranes would be helpful. This position is for an independent, self-motivated scientist. It is an academic research position in a major university in western New York. Box NW581 c/o Nature, 15 East 26 Street, New York, NY10010. (NW581)A

BIOCHEMIST to direct research related to function of enzymes connected with certain immunodeficiency diseases. Strategy requires the cloning of the corresponding genes. PhD/Biochemistry and 3 years postdoctoral experimentation and research involving nucleic acid cloning techniques, protein biochemistry and enzymology. Salary $36,000 per year. Job site: South San Francisco. Send this ad and your résumé to Ad No 9075, PO Box 865, Sacramento, CA 95804 not later than June 22. (NW584)A

Faculty of Earth Sciences, King Abdulaziz University, Jeddah, Saudi Arabia,

invites applications for a faculty position for academic year 1984-85 starting September 1984 at

Associate professor to Professor level in the Department of Geochemistry

to develop and coordinate research in the field of exploration geochemistry and to be involved in the undergraduate and postgraduate teaching programmes. Excellent geochemical laboratory facilities are available.

Ideal candidates would have a Ph.D. degree in geochemical prospecting or very related field with long experience in exploration geochemistry according to which salary would be determined.

Conditions of employment include:

* excellent salary untaxed at source
* free furnished accommodation
* two months annual leave with return air tickets to place of origin

Apply with complete c.v. and list of publications to the Dean, Faculty of Earth Sciences, King Abdulaziz University, P.O. Box 1744, Jeddah, Saudi Arabia.

Applications must reach the Faculty of Earth Sciences not later than one month from date of advertisement.

(W1026)A

2 POST DOCTORAL RESEARCH POSITION IN IMMUNOCHEMISTRY

open immediately at Institut National Recherche Agronomique, at Tours, to study proteins involved in cell adherence. Salary between 12 and 14 000 $ per annum.

Send curriculum vitae and names of references to Dr A. Paraf, Station de Virologie INRA, 78850 Thiverval-Grignon, France.

(W1039)A

DEPARTMENT OF BIOLOGY

Applications are invited for a regular full-time Assistant professor position in Comparative Microanatomy effective 1 July 1985 subject to final budgetary approval. Candidates are expected to have a Ph.D., preferably with post-doctoral experience. While the Biology Department is receptive to applicants from a wide range of backgrounds in Zoology, preference will be given to an candidate whose interests complement those of present faculty and who would make substantial use of our electron microscope facilities. The successful applicant would be expected to develop a vigorous research program and to supervise graduate students. Participation in appropriate cellular, animal histology and animal developmental undergraduate courses would be expected. The Assistant professor salary floor is $26,465. **Applicants should submit, not later than July 31, 1984, a curriculum vitae, personal statement of teaching and research interests, and arrange to have three letters of recommendation sent to:**

Dr J.E. McInerney, Chairman
Department of Biology
University of Victoria
Victoria, B.C. V8W 2Y2

Canadian immigration regulations now require the University to assess applications from Canadian citizens and permanent residents of Canada before assessing applications from other persons. The University of Victoria offers equal employment opportunities to qualified male and female applicants.

(NW580)A

UNIVERSITY OF NEWCASTLE UPON TYNE

CHAIR OF AGRICULTURAL BIOLOGY

Applications are invited for the Chair of Agricultural Biology which has become vacant through retirement. Preference will be given to candidates with interests in applied ecology, including pest and disease management and other aspects of crop improvement. The appointment will carry the headship of the Department of Agricultural Biology for an initial period of five years.

The appointment will be effective from 1 October 1984 or as soon as possible thereafter. Salary will be at an appropriate point on the range for professorial staff which commences at £17,275.

Further particulars may be obtained from the Registrar, University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne NE1 7RU, with whom applications (15 copies), giving the names of not more than three referees, must be lodged not later than 27 July 1984. Candidates from outside the British Isles may submit one copy only.

(2257)A

UNIVERSITY OF BRISTOL MEDICAL SCHOOL

ANIMAL SUPERINTENDENT

Applications are invited for the post of Animal Superintendent for the Medical School. The position involves responsibility for the running of the animal house and applicants should be fully conversant with laboratory animal husbandry and the organisation of a modern animal facility. Since the staff of the animal house number about 20 and belong to at least eight different departments, managerial experience is essential. Fellowship of the Institute of Animal Technicians, whilst not mandatory, would be a desirable qualification. The appointment will be at the level of Grade 8C and in the salary range of £9351 to £10,168 according to experience. (Scales under review). Applications, together with a curriculum vitae, and the names and addresses of two referees, should be sent not later than 20th June to the Personnel Office, Senate House, University of Bristol, from whom particulars may be obtained. (Please quote reference PHC).

(2275)A

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF GENETICS AND BIOMETRY

POST-DOCTORAL RESEARCH ASSOCIATE

Required for a three year appointment to participate in the application of new mathematical techniques to the theory of species formation, and analysis of field data, in spatially distributed populations.

The post would be suitable for applicants with a background in applied maths/physics or a biologist with strong quantitative talents.

Further details from, and applications, cv and names of two referees to, Dr N H Barton, Department of Genetics, University College London, 4 Stephenson Way, London NW1 2HE. (2298)A

UNIVERSITY OF OXFORD

Research laboratory for Archaeology

RESEARCH ASSISTANT IN CHEMISTRY

A post at post-graduate or post-doctoral level is available in the Radiocarbon Accelerator Unit for two years with probable extension to at least four years. The RA will manage the non-routine chemical work of the Unit, and initiate research into the isolation of pure materials from archaeological samples and in the preparation of novel types of ion source target. This work is directed towards improving the accuracy and extending the time-range of radiocarbon dating of micro-samples.

Applicants should have a degree in chemistry and further experience would be an advantage. The salary will be on the 1B scale (£6,625-£10,370 approx) or on the 1A scale (£7,550-£12,195 approx) according to experience and qualifications. Applications should be made to Dr R E M Hedges, Director, Radiocarbon Accelerator Unit, Research Laboratory for Archaeology, 6 Keble Road, Oxford, from whom further details may be obtained. (2234)A

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF BIOCHEMISTRY

LECTURER IN BIOCHEMISTRY/ MOLECULAR BIOLOGY

Candidates should possess a PhD in Biochemistry or Molecular Biology and postdoctoral experience in the application of molecular biology to eukaryotic systems Permanent appointment, following successful completion of the initial probationary period. Salary range £7,190 — £14,125 per annum plus £1,186 London Allowance, according to age and experience. Starting date will be 1 October 1984 or by agreement.

Person appointed will be expected to develop a strong research programme in an area of eukaryotic molecular biology, preferably related to metabolic control, and to contribute to the teaching of undergraduates and MSc students.

Applications, including full cv, the names of two academic referees and a brief indication of future research interests, to Profesor B R Rabin, Department of Biochemistry, University College London, Gower Street, London WC1E 6BT. Closing date: 13 July 1984. (2299)A

MEDICAL RESEARCH COUNCIL
NATIONAL INSTITUTE FOR MEDICAL RESEARCH
DIVISION OF PARASITOLOGY

Applications are invited for a

POSTDOCTORAL POSITION

in the Division of Parasitology to work with Dr K.N. Brown on the immunogenicity of erythrocytes infected with malaria parasites. The appointment will be for 3 years from 1st October 1984. Experience in membrane biochemistry and/or immunology would be advantageous.

The salary will be in the range £8,530 – £10,250 plus £1,186 London allowance, with superannuation provision.

Applications, together with curriculum vitae, research experience and interests and the names of two professional referees should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA before 29th June 1984, quoting ref: P/ 6/ R.

(2289)A

UNIVERSITY OF EDINBURGH
DEPARTMENT OF MEDICINE
(Western General Hospital)

LECTURESHIP
(Non-Clinical)

Applications are invited from suitably qualified science graduates for appointment to a post of Lecturer in the Department of Medicine, Western General Hospital which is currently available. This non-medical post will provide for the permanent appointment in a clinical department of a Scientist who will be expected to undertake research in endocrinology with particular reference to endocrine aspects of hypertension. Candidates should have several years postdoctoral research experience. This should preferably inlcude experience of radioimmunoassay. Previous research in the field of the renin-angiotensin-aldosterone system would be an advantage.

Salary will be at an appropriate point on the non-medical scale £7,190 – £14,125 per annum according to age, qualifications and experience.

Informal enquiries may be made to Professor C R W Edwards (Tel: 031-332 2525 ext 4687).

Further particulars may be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL with whom applications (8 copies) together with the names and addresses of 3 referees should be lodged not later than 6th July, 1984.

Please quote reference no 1139.

(2295)A

The Queen's University of Belfast

RESEARCH OFFICER IN THEORETICAL ATOMIC PHYSICS

Department of Applied Mathematics and Theoretical Physics

The above post is to support research in theoretical atomic and molecular physics and astrophysics which makes extensive use of a Departmental VAX 11/750, a University ICL dual 2988 and a CRAY-1S at the University of London Computer Centre in developing and running large FORTRAN programs. The person appointed will be expected to collaborate with members of staff in this research and to take administrative responsibility in helping to organise this varied computational work. In addition, he or she would be expected to carry out some teaching, particularly on research and computing.

Candidates, preferably holding a PhD degree, must have some experience in computing and have a good knowledge of quantum theory.

Salary scale: £7,191-£11,161, initial placing depending on age, experience and qualifications.

Applications, including curriculum vitae and the names and addresses of two referees should be sent to the Personnel Officer, The Queen's University of Belfast, Northern Ireland, BT7 1NN. Closing date: 18th June, 1984. (Please quote Ref. 84/N).

(2239)A

FACULTY POSITION
MOLECULAR GENETICIST

The Division of Clinical Immunology and Rheumatology is inviting applications for a tenure-track position at the assistant/associate professor level. A strong commitment to research excellence will be the main criterion of selection. Training in molecular biology is required and research interests in the areas of immunology or mechanisms of inflammation preferred. Candidates must have demonstrated research ability and will be expected to establish a strong independent research program. preference will be given to candidates holding an MD degree. opportunities for participating in graduate programs of Basic Science Departments are available. Curriculum vitae, statement of research goals and interests and names of three referees should be sent by August 1, 1984, to: John E Volanakis, MD, Molecular Geneticist Search Committee, Division of Clinical Immunology and Rheumatology, University of Alabama in Birmingham, Birmingham, Alabama 35292. An Equal Opportunity/Affirmative Action Employer. (NW568)A

CSIRO
AUSTRALIA
BIOCHEMIST/ MOLECULAR BIOLOGIST
$A32,367-$A43,941
DIVISION OF PLANT INDUSTRY
CANBERRA ACT

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Plant Industry is a member of the Institute of Biological Resources.

FIELD: Molecular Biology of Symbiosis.

GENERAL: The Division of Plant Industry conducts research on problems fundamental to plant biology and agricultural production. It has extensive research programs in biochemistry and physiology of biological nitrogen fixation concentrating on the root nodule systems of legumes but also including studies of saprophytic diazotrophic bacteria. There is also an active program on molecular aspects of plant and microbial genetics. It is planned to extend research into the molecular biology of the legume symbiosis with some initial concentration on aspects related to energy-yeilding processes.

DUTIES: To initiate research on the molecular biology of the symbiotic association between legumes and their root nodule bacteria.

QUALIFICATIONS: A PhD degree or equivalent qualifications with extensive experience in molecular biology and biochemistry, especially in the fields of nitrogen fixation and/or bioenergetics.

TENURE: Subject to a satisfactory probation period, an indefinite appointment will be made. Australian Government superannuation benefits are available.

APPLICATIONS: Stating full personal and professional details, the names of at least two referees and quoting reference No A4636, should be directed to:

The Chief
CSIRO Division of Plant Industry
GPO Box 1600
CANBERRA ACT 2601
AUSTRALIA

By July 6, 1984.

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER

(W1027)A

United Medical & Dental Schools of Guy's & St. Thomas's Hospitals

NEW BLOOD LECTURESHIP
Prince Philip Research Laboratories
Molecular Genetics

A molecular biologist is required to join a research group in the Prince Philip Research Laboratories at Guy's working on inherited human diseases. The group is part of a multi-disciplinary research unit, with very good laboratory facilities, scientific information service, and other background facilities. The Department contains the South-East Thames Regional Genetics Centre. The molecular genetics group also has well established collaborative arrangements with a number of leading research centres.

The applicant should have experience of recombinant DNA work, e.g. gene cloning, expression or structural analysis. Experience in mammalian cell genetics, gene mapping or linkage analysis would be an advantage.

Applicants wishing to visit the Department should contact Professor M. Bobrow or Dr. F. Giannelli (01-407 7600 ext 2330).

Appointment to this post will be for an initial period of three years. Applicants should not exceed 35 years of age and must not currently hold a permanent UK university appointment.

Salary in range £8,080-£14,125 plus £1,186 London Allowance and Superannuation.

Application forms are obtainable from and should be returned to the Dean, Guy's Hospital Medical School, London Bridge, SE1 9RT not later than 21st June 1984.

(2245)A

THE ROYAL SOCIETY
APPOINTMENT OF EXECUTIVE SECRETARY

A successor is being sought for Dr R.W.J. KEAY, C.B.E., who is retiring at age 65 in mid-1985.

The Executive Secretary is the permanent head of the secretariat with about 100 staff and is responsible under the Officers and Council for the conduct of the administrative business of the Society.

The Society's responsibilities, supported by an annual income of about £8 *million*, cover a wide range of national and international scientific activities. The Executive Secretary is personally involved in all of these and is called upon to represent the Society in many ways at home and abroad.

Applications are sought from persons preferably between 45 and 55 years of age who have had significant personal involvement in scientific research and substantial experience in a relevant administrative post. The Executive Secretary is expected to live in a spacious flat within the Society's premises. The salary is related to that of university professors. The Society has its own pension scheme, with 65 as the normal retirement age.

Those interested should write **in confidence** enclosing a brief **curriculum vitae** and the name of two referees to: SIR JOHN MASON, C.B., F.R.S., Treasurer of the Royal Society, CENTRE FOR ENVIRONMENTAL TECHNOLOGY, IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY, 48 PRINCE'S GARDENS, LONDON, SW7 1LU by 13 July 1984. (2244)A

UNIVERSITY OF STRATHCLYDE

DEPARTMENT OF BIOSCIENCE AND BIOTECHNOLOGY

"NEW BLOOD" LECTURESHIP IN FOOD SCIENCE DIVISION

Applications are invited from candidates under 35 years of age for a lectureship in Food Science. Preference will be given to candidates with postdoctoral research experience in food-related topics. Experience in one or more of the following areas will be an advantage:- biopolymers, rheology, food preservation, food microbiology, food processing and control systems.
Salary will be on the Lecturer Scale (£7,190-£14,125 pa). USS benefit.
Further particulars and application forms (quote ref: 30/84) are available from Staff Office, McCance Building, 16 Richmond Street, Glasgow G1 1XQ.
Closing date for applications: 29 June 1984. (2240)A

United Medical & Dental Schools of Guy's & St. Thomas's Hospitals
NEW BLOOD LECTURESHIP

Department of Chemical Pathology

A molecular biologist with research experience is required in the Department of Chemical Pathology based at Guy's. The post offers the opportunity to work in association with a team involved in the development of malarial vaccines using recombinant DNA Technology. Applicants should submit an outline of research proposals relating to the investigation of human pathology.
Applicants wishing to visit the Department should contact Professor S Cohen (01-407 7600, ext 3365).
Appointment to this post will be for an initial period of three years. Applicants should not exceed 35 years of age and must not currently hold a permanent UK university appointment.
Salary in range £8,080 — £14,125 plus £1,186 London Allowance and Superannuation.
Application forms are obtainable from and should be returned to the Dean, Guy's Hospital Medical School, London Bridge, SE1 9RT not later than 21st June 1984. (2172)A

UNIVERSITY COLLEGE DUBLIN

Applications are invited by the Governing Body of the College for the following full-time statutory appointment:

PROFESSORSHIP OF BOTANY

Prior to application, further information (including application procedure) may be obtained from the Secretary and Bursar, University College, Belfield, Dublin 4. Telephone enquiries: 693244, ext. 431.

The closing date for receipt of completed applications is Thursday, 12th July 1984. (2273)A

RESEARCH POSITION in Paris Laboratory

with possibility of travel and relocation in UK and U.S.A.

Suitable for young independent, ambitious scientist with strong friendly personality.

Should be imaginative, creative and capable of working on unorthodox ideas. Some conversational French necessary.

Training: biochemistry (nucleoproteins), molecular biology, (genetic engineering). Good biology/immunology background.

The work is supported by a British biotechnology company. Salary £8-13,000 p.a.

Please send CV, hand written letter and photo to Box W1038, c/o Nature, 4 Little Essex Street, London WC2R 3LF. (W1038)A

UNIVERSITY OF DÜSSELDORF

ASSOCIATE PROFESSORSHIP (C3) IN MICROBIOLOGY

Applicants are invited for the above position in the Institute of Microbiology, University of Düsseldorf. Candidates should be working in the field of molecular genetics of yeast or filamentous fungi to enable a close cooperation with existing research programs in the Institute. Additional funds and positions are available.

Further information can be obtained from Prof Dr C P Hollenberg, Tel 0211-3114720.

Applications, including curriculum vitae, a summary of research results and the names and addresses of three referees, should be sent to:

The Dekan der Mathematisch-Naturwissenschaftlichen Fakultät der Universität Düsseldorf, Universitätsstraße 1, D-4000 Düsseldorf 1 (FRG).

Closing date 12 July 1984. (W1022)A

Head of Pharmacology

KENT

The Wellcome Foundation Limited is a major group of pharmaceutical and chemical companies with headquarters in the UK and a turnover close to £700m.

This is a key senior appointment reporting to the Director of Therapeutic Research Division. The department is active on a wide variety of forward-looking research projects and comprises some 60 personnel – including scientists, technicians and clerical/secretarial staff.

The prime responsibility of the position will be to direct, manage and co-ordinate the department's activities and resources to meet the overall research objectives within defined cost, quality and time parameters. There is also a requirement to co-ordinate "the development of the science" and ensure that a consistency of high quality of scientific and technical performance is sustained.

Candidates must be able to demonstrate a substantial scientific and managerial track record in a relevant field and have the maturity to promote and develop scientific excellence through personal leadership and motivation. As a senior scientist, the successful candidate must also be capable of contributing to the general debate on scientific research methodology objectives and maintaining a contemporary scientific perspective in this important area of research.

The salary and benefits package will reflect the importance of the position and includes a company car and generous assistance with relocation expenses.

Please write with full c.v. to
Alan Murdoch, Personnel Officer,
The Wellcome Research Laboratories,
Langley Court, Beckenham, Kent BR3 3BS, England.

(2108)A

Wellcome

UNIVERSITY OF NOTTINGHAM

LECTURER IN ZOOLOGY

Applications are invited for the post as Lecturer in Zoology which will become vacant on 1st September 1984.

Candidates will be expected to have research experience in Neuro Chemistry.

Salary will be within the range £7,190 — £14,125 per annum.

Application forms and further particulars, returnable no later than 25th June 1984, may be obtained from Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD. Ref No: 951. (2288)A

FELLOWSHIPS

POSTDOCTORAL FELLOWSHIP IN ONCOGENE RESEARCH

Friedrich Miescher-Institut, Basel, Switzerland

Applications are invited for an internally funded position, of three years maximum duration, to work on the role of oncogenes in human cancer. The Institute provides outstanding facilities in a multidisciplinary basic research environment.

Candidates with a background in molecular biology should write to: Dr Christoph Moroni, Friedrich Miescher-Institut, P.O.B. 2543, CH-4002 Basel, Switzerland. (W1025)E

THE UNIVERSITY COLLEGE OF WALES ABERYSTWYTH

DEPARTMENT OF ZOOLOGY

POST-DOCTORAL FELLOWSHIPS

Applications are invited for two Post-Doctoral Fellowships in parasite Biochemistry, one to work on the cytochrome chain asssociated with peroxidases of parasitic nematodes, the other on the carbohydrate metabolism on Onchocerca. Informal enquiries to professor J Barrett (0970 3111, ext 3259). Salary on the 1A Range for Research and Analogous Staff.

Applications with curriculum vitae and the names and addresses of two referees should be sent as soon as possible to the Staffing Officer, The University College of Wales, Old College, King Street, Aberystwyth, SY23 2AX from whom further particulars may be obtained, (Tel 0970 3177, ext 207). (2262)E

THE ROCKEFELLER UNIVERSITY POSTDOCTORAL FELLOWSHIPS IN MOLECULAR PARASITOLOGY

Applications are invited for two postdoctoral positions to study gene structure and regulation in human malaria parasites and African trypanosomes. The research program of the Laboratory of Molecular Parasitology embraces the study of membrance and genetic phenomena in parasitic protozoa. Applicants should be able to show evidence of achievement and potential in molecular or cellular biology. Experience with parasites could be an advantage but is not essential. Applications, enclosing a full CV and names of at least two referees, should be submitted to: Dr George A M Cross, The Rockefeller University, 1230 York Avenue, New York, New York 10021.

An equal opportunity employer. (NW586)E

THE LONDON HOSPITAL MEDICAL COLLEGE (University of London)

ARC BONE AND JOINT RESEARCH UNIT

RESEARCH FELLOW

An Arthritis and Rheumatism Council Fellowship is available until March 1986 to study local variations in biosynthetic activity in human articular cartilage.

Applications with CV and the names of two referees to Professor H L F Currey, Bone and Joint Research Unit, The London Hospital Medical College, Turner Street, London E1 2AD.

Further information may be obtained from Dr J R Archer, Tel 01-247 8939. (2276)E

ANIMAL DISEASES RESEARCH ASSOCIATION

POSTDOCTORAL FELLOWSHIP

Applications are invited from scientists with experience in molecular biology for a Postdoctoral Fellowship tenable in the Moredun Research Institute, Edinburgh, from August/September 1984 to May/June 1985. The appointee will be required to contribute to one or more current projects on microbial pathogens of ruminant livestock. Salary, for the period of the Fellowship will be within the range £8,000-£10,000 per annum dependent upon qualifications and experience. Further details may be obtained on request. Applications, including Curriculum Vitae and names of 2 referees should be submitted by July 5th to The Secretary, Animal Diseases Research Association, Moredun Institute, 408 Gilmerton Road, Edinburgh, EH17 7JH. (2263)E

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF MICROBIOLOGY

POST DOCTORAL RESEARCH FELLOWSHIP

Applications are invited for this A & FRC funded post to work on the biochemical basis of enhancement of disease resistance in rice by dichlorocycloprotanes. Experience of biochemical aspects of plant-parasite relationships an advantage.

Post tenable for up to ten months from 1st July 1984 or as soon as possible thereafter.

Salary on the Research Fellow 1A scale £7,190 to £11,615 plus superannuation.

For further particulars phone 021 472 1301 ext 2559, quoting reference M4.

No formal application form. Three copies of application, including full curriculum vitae and naming three referees to Assistant Registrar, (Science and Engineering), PO Box 363, Birmingham B15 2TT, by 22 June 1984. (2242)E

continued on page 20

ASSISTANTSHIPS

UNIVERSITY OF CAMBRIDGE

MARINE GEOCHEMISTRY

TWO RESEARCH ASSISTANTSHIPS IN ESTUARINE PROCESSES

The posts are for work on the study of variations in the chemistry of suspended particles in estuaries, especially the role of benthic fluxes and processes at the turbidity maximum in chemical scavenging, and will be in collaboration with workers from the Institute for Marine Environmental Research, Plymouth, the marine Biological Association, Plymouth, and Woods Hole Oceanographic Institution.

Post-doctoral level post salary scale £7,190-£8,080. Post-graduate level post salary scale £6,315-£7,190; both to a maximum of three years, staring 1st October 1984.

For the PDRA post, experience in trace metal geochemistry and/or isotope geochemistry, especially solid-source mass spectrometry would be an advantage. The PDRA will be based at Cambridge but may be expected to take part in field work.

For the PGRA post, experience in oceanographic or estuarine field work and in chemical techniques of water and sediment analysis would be an advantage. The PGRA will be expected to be based at Plymouth for the first part of the project and at Cambridge for the second part.

Applications, including a curriculum vitae and the names of two referees should be submitted to Dr H E Elderfield, Bullard Laboratories, Department of Earth Sciences, Madingley Road, Cambridge CB3 0EZ, by 13 July 1984. (2284)P

QUEEN MARY COLLEGE University of London

MATHEMATICAL SCIENCES — THEORETICAL ASTRONOMY UNIT

Applications are invited for an SERC-funded

POSTDOCTORAL RESEARCH ASSISTANTSHIP

for 2 years from 1 October, for work with Dr M Rowan-Robinson on infrared sources detected by the IRAS satellite. The successful applicant will be expected to work on identification of IRAS sources, to initiate and carry out ground-based observational programmes in collaboration with other groups, and to carry out analyses of relevant IRAS data. Experience of ground-based observations at optical or infrared wavelengths, and of computer programming, an advantage. The College has active groups in several branches of astronomy, ranging from cosmology to interstellar molecules and solar physics.

Salary in range (under review) £8,376-£9,716 pa (including London Allowance). Please apply in writing, enclosing cv and names of 2 referees, to the Senior Personnel Officer, Queen Mary College, Mile End Road, London E1 4NS, by 22 June. (2247)P

CAVENDISH LABORATORY UNIVERSITY OF CAMBRIDGE

POLYMER PHYSICS GROUP

AGRICULTURAL AND FOOD RESEARCH COUNCIL (AFRC)

(Food Physics Division)

A number of graduate and post-doctoral Research Assistantships are being offered as part of the link programme with AFRC being set up at the Cavendish to investigate the physics of macromolecules The positions are for three years in the first instance (starting 1 September 1984 or as soon as possible thereafter) and will involve both experimental and theoretical projects. Applicants with training in Physics or Physical Chemistry will be considered.

Applications should be sent to: Mr J Deakin, Secretary, Cavendish Laboratory, Madingley Road, Cambridge CB3 OHE, quoting ref PPG. (2237)P

STUDENTSHIPS

IMPERIAL COLLEGE UNIVERSITY OF LONDON

DEPARTMENT OF PURE AND APPLIED BIOLOGY

MRC RESEARCH STUDENTSHIP

Applications are invited from candidates with, or expecting to qualify with, a first class honours or 2(1) degree, for a 3 year studentship to study the biochemical/molecular organisation of the sexual stages of the malarial parasite plasmodium falciparum. The student will be expected to have a sound working knowledge of biochemical techniques, will join an active research group based at the department's field station at Ascot, and will be registered for a higher degree in the University of London.

Applications with CV and the names of two referees to Dr R E Sinden, Imperial College Field Station, Silwood Park, Ascot, Berks SL5 7PY (Closing date May 31st 1984).

(2279)F

QUEEN MARY COLLEGE (University of London)

SCHOOL BIOLOGICAL SCIENCES

RESEARCH STUDENTSHIP

Applications are invited for an SERC studentship to work on a project involving the study of tetrachromatic vision in fresh-water fish. Training will be given in spectrophotometric and electrophysiological techniques. Applicants should possess a first or upper second class degree in biological sciences with a physiological background.

Applications, including curriculum vitae, and the names of two referees should be sent to Dr J K Bowmaker, School of Biological Sciences, Queen Mary College, Mile End Road, London, E1 4NS. (Tel: 01-980 4811, ext 4110).

The School of Biological Sciences has three SERC studentships available for work on a wide range of biological topics. Further details available from the above address.

(2272)F

UNIVERSITY OF ABERDEEN

DEPARTMENT OF ZOOLOGY

has been awarded three

SERC STUDENTSHIPS

starting in October 1984. Applications are invited from students with good Honours Degrees and from those expecting to graduate shortly, and who wish to carry out research in the following areas:

Cell Biology, Experimental Parasitology, Insect Endocrinology, Mammalian Reproductive Energetics, Marine Biology, Neurobiology.

Enquiries and applications should be addressed to Professor W Mordue, DSc, Department of Zoology, University of Aberdeen, Tillydrone Avenue, Aberdeen AB9 2TN. Tel No (0224) 40241, ext 6427.

JOHN INNES INSTITUTE

Colney Lane, Norwich NR4 7UH

RESEARCH STUDENTSHIP

Applications are invited for a three year research studentship to study the physiology/biochemistry of the relationship between photosynthesis and respiration in higher plants.

Applicants should have, or expect shortly to have an Honours degree (2i ir better) in a Biological Science.

Applications, with curriculum vitae and names and addresses of two referees, should be sent to Professor H W Woolhouse at the above address, not later than 20 June 1984.

(2290)F

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF PLANT BIOLOGY

RESEARCH STUDENTSHIPS

Applications are invited for the following studentships tenable from October 1st.

1. SERC CASE Studentship in collaboration with MAFF Laboratory in Harpenden, on the detection and elimination of viruses in true potato seed.

2. SERC CASE Studentship in collaboration with the Scottish Crops Research Institute, on physiological aspects of frost tolerance in blackcurrants.

3. SERC Quota Studentship, tenable in one of the following subject areas: biochemical aspects of plant-pathogen recognition; physiology of aluminium tolerance in tree mycorrhizas; physiology and ultrastructure of chalk and silica deposition by algae.

Further details are available from Professor J A Callow, Department of Plant Biology, University of Birmingham, B15 2TT and applications should contain a full cv and names of 2 referees. (2261)F

UNIVERSITY OF LANCASTER

DEPARTMENT OF ENVIRONMENTAL SCIENCES

SERC RESEARCH STUDENTSHIP

Tenable from 1st October, 1984

Applicants holding or expecting at least an upper second class honours degree in a physical/geophysical science field may apply for either of the following topics:

1. Study of fluid dynamic processes in silicate magma/sulphur systems with application to volcanism on Io.

2. Investigation of the photometric properties of the surfaces of Ganymede, Callisto and Europa using Voyager data.

Applicants should send cv and names and addresses of two referees to Dr L. Wilson, Dept. Environmental Sciences, University of Lancaster, from whom further information can be obtained. **(2296)F**

WYE COLLEGE (University of London)

MAFF STUDENTSHIP IN AGRICULTURAL LAND CLASSIFICATION

Tenable for three years, starting on October 1st, the studentship is to relate crop yield and economic performance to physical land properties. Applicants, preferably competent in the use of computers, should hold or expect to obtain a First or Upper Second Class Degree. Apply, with Curriculum Vitae and the names of two referees, to Dr C P Burnham, Department of Environmental Studies and Countryside Planning, Wye College, Ashford, Kent. TN25 5AH. Tel No (0233) 812401.

Wye College is an equal opportunities Employer. (2281)F

UNIVERSITY OF LEICESTER

DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS

SERC RESEARCH STUDENTSHIP IN PHARMACOLOGY

Applications are invited from good honours graduates, or from those expecting to graduate in pharmacology, biochemistry or physiology this year, to work on the following project from October 1984.

Interactions of neurotransmitter receptors linked to adenylate cyclase and inositol phospholipid hydrolysis in brain tissue.

The study will involve techniques to directly examine inositol phospholipid hydrolysis, cyclic nucleotide production, receptor labelling and assay of endogenous neurotransmitter release from brain slices.

Applications (including cv and the names of two referees) should be sent to Dr S R Nahorski, Department of Pharmacology and Therapeutics, Medical Sciences Building, University of Leicester, University Road, Leicester, LE1 7RH, as soon as possible. (2241)F

UNIVERSITY OF EDINBURGH

DEPARTMENT OF BACTERIOLOGY

MRC RESEARCH STUDENTSHIPS

Applications are invited for one of the following projects.

1. Phagocyte lectin receptors and their role in immunity to bacteria.

2. The pathogenesis and cell surfaces of Bacteroides species.

3. Detection of Hepatitis B by DNA cloning techniques.

Applicants should hold, or expect to obtain, a 1st or upper second class honours degree in a relevant biological science.

Applications, including a curriculum vitae and names of two academic referees should be sent, as soon as possible, but in any case not later than 20 June, to Professor J G Collee, Department of Bacteriology, University of Edinburgh Medical School, Teviot Place, Edinburgh EH8 9AG. (2294)F

PORTSMOUTH POLYTECHNIC

Biophysics Group

SERC POSTGRADUATE STUDENTSHIPS IN CHROMATIN RESEARCH

Applications are invited from graduates or final year students in biochemistry, chemistry or a related subject. The projects will involve the study of structure/function relationships in chromatin at the level of the nucleosomal supercoil.

Further particulars and application forms from Professor C Crane-Robinson, Biophysics Laboratories, Portsmouth Polytechnic, St Michaels Building, White Swan Road, Portsmouth. PO1 2DT. Ref: B16.

(2260)F

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

THE COURTAULD INSTITUTE OF BIOCHEMISTRY

London W1P 7PN

CANCER RESEARCH CAMPAIGN STUDENTSHIP

Applications are invited for research studentship within the CR Endocrine Tumour Molecula Biology Group under Professor R Craig for a period of three years fro 1 October 1984. The project will b concerned either with the structu and regulation of the hyma calcitonin/CGRP gene in thyroi and lung tumours, or the applicatio of recombinant DNA techniques i the study of human breast cancer.

Candidates should have or expe to obtain a first or upper second cla honours degree preferably in Bi chemistry or Genetics.

Applications enclosing names an addresses of two referees should b sent as soon as possible to Professo R K Craig at the above address.

(2269)F

STUDENTSHIPS

QUEEN MARY COLLEGE (University of London)

SCHOOL BIOLOGICAL SCIENCES

SERC CASE STUDENTSHIP

THE MOLECULAR GENETICS OF PROTEASE SECRETION IN YEAST

Applications are invited for the above studentship. The successful applicant would be expected to register for a PhD degree. The project in collaboration with Distillers Company (Yeast) Ltd, will be jointly supervised by Dr I Evans (DCL) and Professor E A Bevan (QMC).

Applications with a curriculum vitae and the names of two referees should be sent as soon as possible to Professor E A Bevan, School of Biological Sciences, Queen Mary College, Mile End Road, London, E1 4NS.

The School of Biological Sciences has three SERC studentships available for work on a wide range of biological topics. Further details available from the above address. (2271)F

UNIVERSITY OF EDINBURGH

DEPARTMENT OF VETERINARY PHYSIOLOGY

SERC RESEARCH STUDENTSHIP

Applications are invited for a studentship tenable for three years from October 1984 for studies leading to the PhD degree. Projects available are in the area of peripheral and central somatosensory neurophysiology.

Enquiries to: Dr A D Short, Department of Veterinary Physiology, Royal (Dick) School of Veterinary Studies, Summerhall, Edinburgh EH9 1QH. Tel: 031-667 1011 ext 5249. (2265)F

UNIVERSITY OF NOTTINGHAM

DEPARTMENTS OF BOTANY AND PHARMACY

POSTGRADUATE RESEARCH STUDENTSHIP IN MICROBIAL BIOCHEMISTRY

Applications are invited for a studentship funded by a University of Nottingham Research grant. The project involves a study of the physiology and biochemistry of production of antifungal antibiotics under the supervision of Dr J F Peberdy (Department of Botany) and Professor B W Bycroft (Department of Pharmacy).

Applicants should have or expect to have a First or Upper Second Class honours degree in Microbiology and/or Biochemistry. The award is for two years, in the first instance, commencing October 1984.

Applications, including the names of two academic referees should be sent to Dr J F Peberdy, Department of Botany, University of Nottingham, Nottingham NG7 2RD. (Tel 0602 506101 ext 2204) to arrive not later than June 22nd, 1984. (2287)F

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS

TWO RESEARCH STUDENTSHIPS

Two MRC funded Research Studentships are available for work on the following projects:-

(a) The retrograde axonal transport of proteins in peripheral nerves

(b) The kinetics and pharmacological effects of primaquine formulations

The latter project will be carried out in association with the Department of Parasitology, Liverpool School of Tropical Medicine.

Candidates should possess or expect to obtain a first or upper second class honours degree in pharmacology or related subjects.

Applications to the Registrar, The University, PO Box 147, Liverpool L69 3BX. Quote Ref: RV/530/N. (2232)F

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

DEPARTMENT OF PURE AND APPLIED BIOLOGY

SERC RESEARCH STUDENTSHIP

Applications are invited for a studentship starting 1 October 1984 for three years. The work involves the experimental and/or theoretical study of population dynamics in heterogeneous environments using insects as subjects.

Applicants must possess or expect a good honours degree in biology of mathematics and should send a full CV and arrange for two references to be sent to Professor M P Hassell, Imperial College, Silwood Park, Ascot, Berks SL5 7PY. (2293)F

UNIVERSITY OF LONDON

INSTITUTE OF PSYCHIATRY

DEPARTMENT OF NEUROLOGY

SERC RESEARCH STUDENTSHIP

Applications are invited for a CASE Studentship tenable from October 1984. The position is renewable for 3 years subject to satisfactory progress. The applicant will be expected to register for a higher degree.

The work involves the behavioural assessment of neuroleptic-induced abnormal involuntary movements in rodents. The collaborating body is Organon Laboratories.

Applicants should be recent graduates in a biological science with a first class or upper second class honours degree.

Applications, with a curriculum vitae and the names of two references, should be sent to Dr P Jenner, Department of Neurology, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF. Closing date: 29 June 1984. (2270)F

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London)

DEPARTMENT OF NEUROLOGICAL SCIENCE

ANTIGENIC DETERMINANTS ON HUMAN ACETYLCHOLINE RECEPTOR

An MRC Studentship

is available for 3 years from October 1984 for a Research Student to join an MRC Programme Grant-funded group of basic and clinical scientists studying the cause and treatment of myasthenia gravis, to work on the antigenic determinants on human acetylcholine receptor using biochemical techniques and monoclonal antibodies.

Applicants should have or expect to obtain a first class or upper second class degree in biochemistry or immunology.

Curriculum Vitae, including the names of two academic referees, should be sent to Dr A Vincent, Department of Neurological Science, RFHSM, Rowland Hill Street, London NW3 2PF by 22 June 1984. Further details are available by request. (2286)F

THE UNIVERSITY OF SHEFFIELD

POSTGRADUATE STUDENTSHIPS IN TUMOUR BIOLOGY

Applications are invited for 2-3 studentships in the Departments of Surgery and Virology tenable from 1 October 1984. The successful candidates will work in the field of tumour biology/biochemistry interface.

Applications, including curriculum vitae and the names of two referees, should be sent as soon as possible to Mr K Rogers, Clinical Sciences Centre, Northern General Hospital, Sheffield S5 7AU. Please quote ref R96/G. (2254)F

CHARING CROSS HOSPITAL MEDICAL SCHOOL (University of London)

DEPARTMENT OF BIOCHEMISTRY

SERC Post Graduate Studentship

Applications are invited for a three-year studentship leading to a PhD.

The candidate will work in the newly established Gene Structure and Function Group, either with Dr L A Archard or with Professor A D B Malcolm. Projects include: Analysis of Coxsackie virus; Orthopox virus gene expression; Campylobacter toxin gene expression; Effects of DNA conformational changes; Role of nucleosome phasing in transcription.

Further details are available by telephoning 01-748 2040, ext 2835. (2259)F

UNIVERSITY OF WARWICK

POSTGRADUATE STUDENTSHIPS IN BIOLOGICAL SCIENCES

Applications are invited from persons possessing, or expecting to obtain in June 1984, a First Class or Upper Second Class Honours Degree in Microbiology, Biochemistry, Genetics or a related subject to work on the following projects:

i) An SERC Biotechnology Directorate-funded project to work on the biochemistry and physiology of thermophilic aromatic-utilizing bacteria with a view to considering their potential application in the production of high value added chemicals. The studentship will be under the supervision of Professor H Dalton.

ii) An SERC Quota funded project to work on the molecular biology on the heterocysts in Cyanobacteria. The studentship will be under the supervision of Professor N G Carr.

Applicants should send a cv, together with the names and addresses of two referees, to the Executive Officer, Department of Biological Sciences, University of Warwick, Coventry, CV4 7AL, indicating in which of the above studentships they are interested.

Informal enquiries can be made direct to Professor H Dalton at the above address, 0203-24011, ext 6025, or direct to Professor N G Carr, Biochemistry Department, University of Liverpool, 051-709-6022, ext 2518. (2268)F

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF PHYSICS

SERC PhD STUDENTSHIP

AMORPHOUS AND CRYSTALLINE QUANTUM WELL SEMICONDUCTORS

Applications are invited from graduates with a class I or II.1 Honours degree in physics, materials science or electronic engineering, for a SERC Information Technology award, tenable from 1 October 1984 to study photoluminescence in extremely thin layer structures of amorphous silicon which show quantum size effects. Comparative studies of GaAs superlattices will be included. The successful candidate will join an established group in the field of amorphous semiconductors especially interested in the study of photo- and electro-luminescence, using lasers and related opto-electronic techniques. This work is being extended to include quantum size effects in both amorphouse silicon and crystalline III-V semiconductors. The group collaborates actively with a number of workers in the device field. The project will involve a wide range of solid state techniques with emphasis on the physics of these materials.

Applications, with curriculum vitae and the names of two referees to Professor I G Austin/Dr T M Searle, Department of Physics, The University, Sheffield S10 2TN as soon as possible. Please quote ref no R93/G. (2252)F

CONFERENCES and COURSES

UNIVERSITY OF SUSSEX

M.Sc. Courses in Biochemistry

The University offers four full-time, one-year M.Sc. courses in Biochemistry:

GENERAL BIOCHEMISTRY
BIOCHEMICAL ENDOCRINOLOGY
GENETIC MANIPULATION AND MOLECULAR BIOLOGY
PLANT BIOCHEMISTRY AND BIOENERGETICS

and places (without financial support) on most of these are available for the 1983/84 session. General Biochemistry may also be taken as a two-year course. Research projects are included in each course, related to research currently underway in the Biochemistry Group. Applicants should normally possess at least a 2nd Class Honours degree or its equivalent in Biochemistry or in a Biological, Chemical or Medical Science.

Research Studentships in Biochemistry

Several research council studentships are available to support students working towards a research degree. One of these is earmarked to an SERC grant for **immunological studies of plant mitochondrial biogenesis** (Dr A.L. Moore). Others may support students working on any of the research topics of interest to the department, especially: (1) **regulation of transcription in eukaryotes**, (2) **immunoassays for nuclear antigens**, (3) **hormonal and nutritional control of growth and protein synthesis**, (4) **hormonal regulation of gluconeogenesis and ureogenesis.**

Application forms and further details for both MSc. courses and research studentships may be obtained from the Subject Chairman of Biochemistry, School of Biological Sciences, University of Sussex, Falmer, Brighton, Sussex BN1 9QN. (2297)C

THE UNIVERSITY OF LEEDS
MSc IN CARDIOVASCULAR STUDIES

A one-year course which provides a scientific training for investigations into the human and other cardiovascular systems. The course is open to graduates in medicine, physiology and related disciplines and commences 1 October.

For further details write as soon as possible to the Course Tutor, Department of Cardiovascular Studies, The University, Leeds LS2 9JT. (2255)C

Southampton THE UNIVERSITY

MSc in Electrochemical Science

This SERC approved course offers a balanced combination of lectures and practical work. The aim of the course is to introduce the techniques and concepts of electrochemical science and to show how they are applied to practical problems. In the second half of the course students carry out a research project. Assessment is by written examination and by oral examination of a dissertation. SERC studentships are available for suitably qualified applicants.

Further details may be obtained from:
Dr L.M. Peter
Department of Chemistry
The University
Southampton SO9 5NH
(2285)C

GRANTS and SCHOLARSHIPS

WELSH NATIONAL SCHOOL OF MEDICINE
(University of Wales)
DEPARTMENT OF CHILD HEALTH

Applications are invited for a post-graduate scholarship to investigate androgen action and metabolism in disorders of sexual differentiation in humans, using tissue culture and cell fractionation techniques.

Applicants should have, or expect to gain, a first or upper second class honours degree in Biochemistry or a related science discipline.

The scholarship will commence in Summer/Autumn 1984 and is tenable for a 3 year period (subject to a probationary year). The results are expected to be submitted for a PhD degree.

Further particulars and application forms (quoting Ref No C10/62) may be obtained from the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff, CF4 4XN (Tel No 0222-755944 Ext 2296) to whom applications should be sent by 25th June, 1984. (2274)H

WORKSHOP

WORKSHOP ON ABNORMAL CELLS, NEW PRODUCTS, AND RISK

Co-sponsored by:
FDA, NCI, NIAID, NHLBI, and CDC
will be held on July 30-31, 1984
at the NIH in Bethesda, MD, USA

The meeting has been organized to review issues and data relating to the use of abnormal cells in the production of drugs and biologics. Particular attention will be focused on three areas: (1) residual cellular DNA in products; (2) viruses endogenous to the cell substrate; and (3) residual cellular proteins in products. Discussions will follow the presentation of data, and there will be an attempt to develop consensus in each of the three areas during the afternoon of the second day. The Public Health Service Agencies co-sponsering this workshop believe it will assist them in making decisions on the support of research, the regulation of products, and the use of products derived from abnormal mammalian cells. The meeting is open to the public; however, individuals planning to attend should send their name and address to: Mary Ann Tourault, Food and Drug Administration, 8800 Rockville Pike, Bethesda, MD 20205 so that additional information can be sent in advance of the meeting. (NW575)V

FELLOWSHIPS *Continued from p. 16*

DEEP DIVE RESEARCH

As part of a research program in deep dive medicine The Norwegian Research Council for Science and the Humanities has established 5 3-years Research Fellowships within neurology/neurophysiology/thermophysiology, circulation and farmacology.
The salary is Nkr 113.996-192.119, depending on qualifications. Further information may be requested. **Application and 3 copies of scientific papers within June 25 1984 to: Norwegian Research Council for Science and the Humanities, Munthes gt. 29, 0260 Oslo 2, Norway. Telephone (02) 56 52 90** (W1034)E

UNIVERSITY OF ABERDEEN
DEPARTMENT OF OPHTHALMOLOGY
POST-DOCTORAL RESEARCH FELLOWSHIP

Applications are invited fro a post-doctoral position to work on the cell biology of proliferative retinal disease. The work will initially be directed towards developing an in vitro model of retinal angiogenesis using isolated retinal capillary endothelial cells grown on vitreous explants and artificial collagen substrata.

This is the first of a number of research appointments to the new University Department of Opthalmology and the successful applicant will be expected to participate in the development of the Department. Applicants should have or should be about to complete a PhD in Moecular and/or Cell Biology.

Salary will be on the Range 1A scale for Research and Analogous Staff £7,190 to £11,615 per annum (under review) with appropriate placing.

The position is available immediately, although the starting date is negotiable, and will be for 3 years.

Further particulars and application forms from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 29 June 1984. (2282)E

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF BIOCHEMISTRY

POST DOCTORAL RESEARCH FELLOWSHIP

Applications are invited for the above SERC funded post to work with Dr S J W Busby on a study of the regulation of gene expression in E coli at the level of transcription and translation. In particular the candidate will investigate the role of messenger sequence in the efficient initiation of translation. Applicants should have an interest in the application of recombinant DNA technology.

Post tenable for up to three years from the soonest possible date.

Salary on the Research Fellow 1A scale £7,190 to £11,615 plus superannuation.

For further particulars phone 021 472 1301 ext 2559, quoting reference B6.

No formal application form. Three copies of application, including full curriculum vitae and naming three referees to Assistant Registrar (Science and Engineering), PO Box 363, Birmingham B15 2TT, by 22 June 1984. (2243)E

Typesetting: J.W. Arrowsmith Ltd, Bristol and Outlife Graphics Ltd., London EC4Y 0HP. NATURE'S BIOREACTOR

The New Bio-Response MCT* (Mass Culturing Technique) System Delivers Monoclonal Antibodies And Other Mammalian Cell Products When You Need Them—From Grams To Kilograms.

Insufficient quantities of desired peptides are a key cause of expensive research and production delays. The MCT system is a *new* and *unique* mammalian cell culturing process designed to overcome the obstacle of insufficient quantities of peptides by delivering the quantity you need...*when you need it!* Additionally, every step in MCT production has been developed to contain costs now and in the future while maintaining exceptional purity and quality in mammalian cell proteins.

Quantity

Unlike conventional cell-culture methods, the MCT system uses "fresh," free-flowing lymph directly from a cow. Following treatment, the lymph is continuously diffused into and out of a growth chamber. This nearly *in vivo* growth environment stimulates continuous and optimal protein secretion. The result? Large quantities of desired proteins enabling you to move to the clinic or market...*faster.*

Cost

Unlike conventional cell-culture methods that require extensive labor forces and expensive growth mediums, Bio-Response's MCT is a closed, steady-state system. In essence, the MCT system starts with a low-cost lifeline—a feeding cow—and ends with a pure, quality product. MCT ...*an optimal system at low cost.*

Purity

Unlike conventional cell-culture methods, the MCT system is designed to insure purity without tedious processing. By directing the lymph across semi-permeable membranes, MCT provides both separation of media protein from desired cell products, and a continuous nutrient flow. The ability to add or withdraw from the chamber to maintain optimal cell density permits continuous harvest of a highly pure product.

Quality

Unlike conventional methods of production that attempt to create biologically active mammalian cell products, the MCT system provides a pure-mammalian product—an exact copy of the original protein and, in the case of non-antibody polypeptides, uncompromised by inappropriate glycosylation and disulfide bond formation. There is a growing consensus favoring products produced in a mammalian cell-culture system, such as the Bio-Response MCT system.

Circle No. 14 on Reader Service Card.

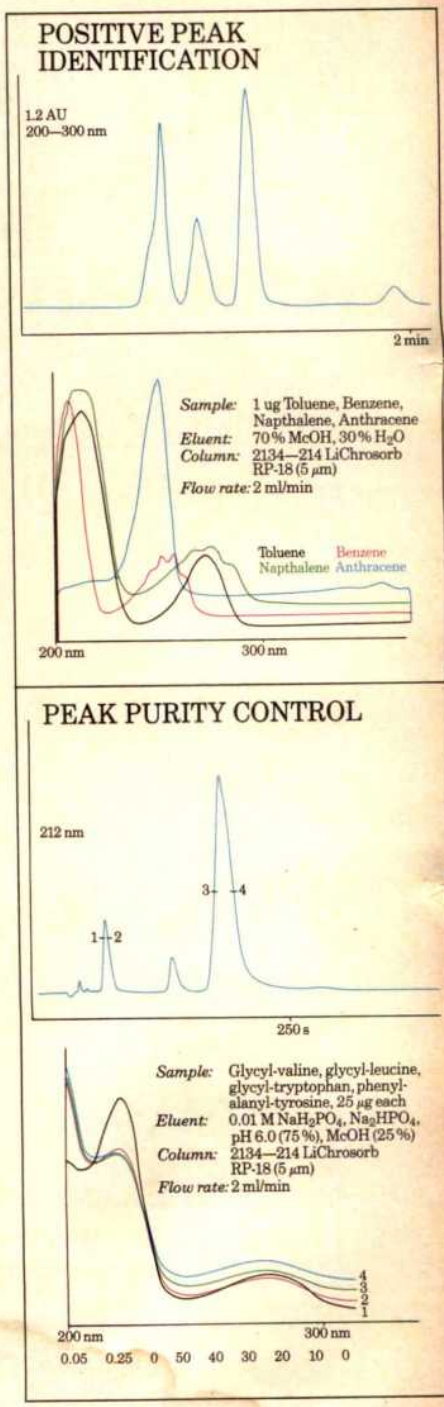
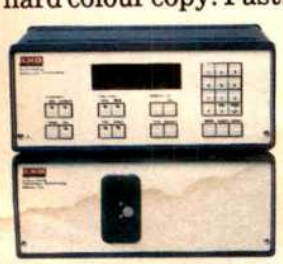
QUASI-LIQUID CRYSTALS



COMPUTERS IN THE LABORATORY

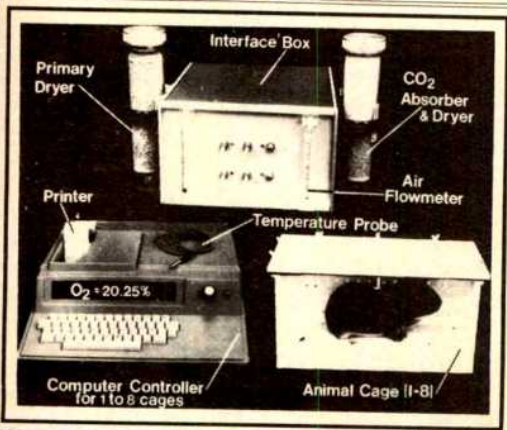
A SIMPLE CHECK ON EVERY PEAK



WITH LKB's RAPID SPECTRAL DETECTOR

A computer generated contour map of the total absorbance pattern after separation—colour coded to show different levels of absorbance for each isogram. The vertical and horizontal axes are time and wavelength respectively. Built-in cursors let you slice through the isogram in both time and wavelength domains.

Peak purity control and positive component identification—rapid, reliable and surprisingly simple. An analytical follow-through no other system offers, with a chromatographic display that delivers you peaks in perfect detail. And an innovative slicing technique to track through each peak, to generate spectra at lightning speed. Spectral selection at peak maxima gets you positive component identity. Automate for superimposed spectra and you've got peak purity control. Authentic. Definitive. LKB's Rapid Spectral Detector, powered for instant data, processed for in-depth development, interfaced to access optimal chromatograms and spectra—from storage—through the video screen—to hard colour copy. Fast. Easy. Clearly out front.



You won't find a more reliable way to acquire, process and present your chromatographic information. So why not check it? Get in touch with LKB, and we'll send you the brochure that gives you a complete check on the very best in modern diode array technology. You'll find it infinitely rewarding, just like our new Rapid Spectral Detector.

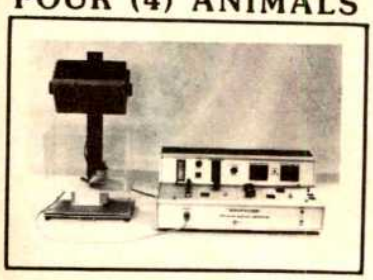
LAB-ANIMAL RESEARCH EQUIPMENT

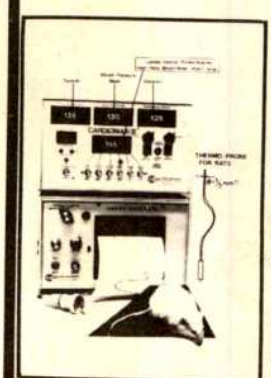
O_2 consumption CO_2 production Respiration Rate

- Continuous measurement of O_2, CO_2 and respiration rate over a 24 hour period in ml/kg of body weight/hour in STP units for 1 to 8 animals.
- Prints results every four (4) minutes.
- System adaptable to small or large animals.
- Continuous airflow through system.
- High accuracy, >98% of full measuring range e.g. typical error ±30 ml oxygen/kg/hour in 3000 ml oxygen/kg/hour range.



Apple-Thermometer

"Thermex" interface converts Apple II computer into an automatic printing 16 channel thermometer. Accuracy in biological temperature range is 1/10 degree C. Variety of rectal, intravenous, implantable probes, etc. available. Stores results on the floppy disk. Data transfer to host computers via RS-232 line possible.

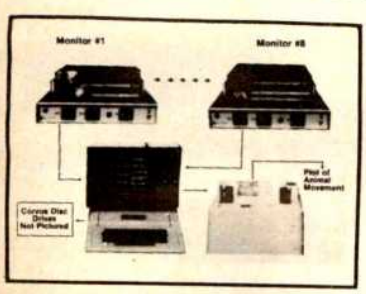


Applications: Prints and measures temperature in multiple animals, pyrogenic activity, blood flow distribution, etc.

STARTLE RESPONSE MONITOR TESTS FOUR (4) ANIMALS

System produces surprise stimuli according to a preset program, and measures and records the force of the response and the response time. Tested and recorded by the system are the force of the startle reflex, the reaction time, and habitation characteristics. The system is also equipped with a stimulus programmer for fully automatic operation. The system also includes an automatic printer with its own timer.

RATS!! CARDIAC OUTPUT BY THERMODILUTION



Cardiac Output Computer utilizes 1/3 and 1/2 mm microprobes to measure cardiac output in rats. The same instrument works with a variety of other catheters when measuring cardiac output on dogs, horses or humans. Dye dilution densitometer available as an option.

FEEDING & DRINKING MONITOR

Eight electronic precision scales interfaced to Apple-II computer serve as solid or liquid food consumption sensors.

APPLE-II INTERFACE FOR EIGHT (8) ANIMAL ACTIVITY MONITORS

Multiple infrared beams monitor animal activity in the cage. Different animal cage sizes are available, e.g. 15" x 15" or 1m x 1m. Apple-II computer computes in periodic intervals the following information: total distance traveled, number of rearings, patterns of movements, separate number of stereotypic and ambulatory movements, time spent in each of 16 squares of "Open Field," number of entries into each square, left, right and partial rotations and histograms for each of the above for each animal.

ALSO FULL LINE OF:

- ★ **Animal Activity Meters for Rodents, Fish and Insects**
- ★ **"Rota-Rod" System with Electric Shock Enticement for Testing Endurance and Coordination**
- ★ **TV Camera Video Digitizer and Apple-II Computer for Animal Activity and Social Contact Measurements (Automatic!)**
- ★ **Animal Tremor Monitor**
- ★ **Anxio-Meter for Testing Anxiety (according to Vogel principle).**
- ★ **Shuttle Boxes!!! Computerized Reflex Conditioners for Testing Memory and Learning.**

Forthcoming

the 'Practical Approach' series

Microcomputers in Biology a practical approach

Edited by
C. R. Ireland and S. P. Long

The microcomputer is now a familiar and essential item of equipment in the biology laboratory. It is used not only for the analysis of data and control of experiments but also for the control of other equipment. This book is a guide to the uses and limitations of the microcomputer in a wide variety of biological techniques. The chapters include 'ready to work' fully explained programs in BASIC. This will enable readers with little or no experience in programming to make immediate practical use of the information.

Software

The programs described in the book will be available on floppy disc at a reasonable price for use with the following computers: *Apple II, Apple IIe, Commodore PET, IBM P/C, ANACOMP and the BBC Micro.*

Contents (provisional)

An introduction to microcomputers and microcomputer systems *C. R. Ireland and S. P. Long*
Communicating with microcomputers *R. J. Beynon.*
Data-logging with microcomputers *K. C. Persaud.*
Graphical techniques with microcomputers *G. A. Place.*
Statistical analyses with microcomputers *S. P. Long and C. R. Ireland.*
Microcomputers in the analysis of enzyme reactions *J. Crabbe.*
Microcomputers in nucleic acid research *R. J. Smith.*
Microcomputers in spectrophotometry *A. Lodola.*
Microcomputers in chromatography *R. J. Smith.*
Microcomputers in centrifugation *J. Steensgaard and D. Rickwood.*
Microcomputers and environmental control *S. W. Burrage and J. Varley.*
Plus appendices.

Summer 1984; 300pp (approx)
0 904147 57 6 (soft)
Around £11/US$22.

Of related interest

The Applications of Computers to Research on Nucleic Acids II, Parts 1 and 2 £30/US$60.
The Applications of Computers to Research on Nucleic Acids I, £12/US$24.

(Both books originally published as issues of the journal *Nucleic Acids Research*)

For more information Circle No.7 on Reader Service Card.

IRL PRESS
BIOSCIENCE
SOFTWARE

Bioscience software

A new series of instructive and imaginative software for the BBC Microcomputer. Covering aspects of biology, botany, zoology and chemistry, the programs are suitable for teaching at both undergraduate and high school level.

The programs use sound and high colour graphics to illustrate material which is otherwise difficult to teach. They include multiple-choice questions. Each program is supplied with a booklet which provides complementary material.

The first six program packages are:

Muscle Contraction *A. G. Booth.*
pH/Titration *M. F. Chaplin.*
Protein Structure and Enzyme Activity *M. F. Chaplin.*
Photosynthesis—The Light Reactions *A. J. Bleasby.*
The Genetic Code and Protein Synthesis *E. J. Wood.*
Nucleaic Acid Structure and Synthesis *J. H. Parish.*

The programs will be available in September 1984.
Price of each program £19.95/US$40.00

For more information Circle No.8 on Reader Service Card.

COMPUTER APPLICATIONS IN THE BIOSCIENCES

Editors:

R. J. Beynon
University of Liverpool

J. A. Peterson
University of Texas

This new quarterly journal will provide an international forum for the exchange of information on computing in the life sciences.

Issues will contain:

- High quality refereed papers describing programs and their applications.
- Comprehensive and authoritative reviews, either 'state-of-the-art' for the specialist or introductory in nature for the beginner.
- A 'communications' section containing short descriptions of complete software.
- Product news and reviews, program use reviews, software availability, book reviews and literature surveys.
- A reader enquiry service so that readers can order programs and request information on products reviewed or advertised.

Annual subscription prices (4 issues p.a.)

Individuals	£25/US$50
Libraries	£40/US$80

Call for Papers
Scientists who wish to submit papers for publication should contact the appropriate Editor below, from whom detailed 'instructions to authors' are available.

Sensitive It Is. Radioactive It Isn't.

The DNA Detection System From BRL.

Until now, only a radioactive label could provide the sensitivity required for detecting small quantities of DNA. Today—with BRL's new DNA Detection System—*you can visualize even single copy genes without radioactivity.*

What the DNA Detection System is:

Sensitive. Using this enzyme-based system, together with the nonradioactive label biotin-11-dUTP, *you can detect 2 to 5 picograms of DNA.* The key to this extraordinary ability is a polymer of alkaline phosphatase, which provides far greater sensitivity than horseradish peroxidase.

Reliable. *Only BRL provides pretested reagents for making DNA test strips* on your nitrocellulose. Developed beside your filter, test strips act as an internal control, enabling you to monitor each visualization reaction.

Easy to use. All the reagents in the system—biotinylated poly alkaline phosphatase, streptavidin, dyes, biotinylated control DNA and DNA dilution buffer—are prescreened for use together. They are packaged in a convenient plastic container in which the filter can be developed. In addition, BRL's DNA detection experts have compiled a clear, step-by-step instruction manual which is included with the system. Our scientists also can assist you when you call the BRL Tech-Line™.

Flexible. You can label your DNA with biotin-11-dUTP and the nick translation reagents or labeling protocol of your choice. Of course, if you choose to purchase BRL's own Nick Translation Reagent System and our Biotin-11-dUTP, you can be assured of optimal results, because they are completely qualified for use with our companion DNA Detection System.

Rapid and inexpensive. Faster than autoradiography, the DNA Detection System actually costs less to use and requires no expensive equipment.

What the DNA Detection System Isn't:

Radioactive. Used with biotin-11-dUTP, our system has none of the safety, stability and disposal problems associated with radiolabeling for autoradiography.

Ask for our brochure and try BRL's DNA Detection System. You'll like it for what it is—and for what it isn't.

nature

NATURE VOL. 309 14 JUNE 1984

COVER

A spiropyran quasi-liquid crystal viewed through a polarization microscope. These crystals have the properties of conventional liquid crystals, but also show structures not normally seen in such materials, for example clusters of non-birefringent microcrystals. Quasi-liquid crystals are discussed on p.608.

SCIENCE IN THE LOW COUNTRIES

- *Will the policy of "concentrating" the universities in Holland and Belgium create more problems than it solves?*
- *Is Belgian science stagnating?*
- *What would be the effect of increased government control over Dutch research policy?*

These and other questions are examined in *Nature*'s special supplement on Science in the Low Countries.
Extra copies of this issue are available now from the address given below.

- Magnetostratigraphy of Hadar hominid site
- Mantle anisotropy
- Platinum from space
- γ-ray pulsar
- Protective toxin in butterfly diet

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

Recent developments in molecular biology, many of which have been described by their authors in *Nature*, are helping to clarify the causes of cancer. With each passing week, more and more people consider that a full understanding of cancer cannot be long delayed. But the implications for physicians and their patients are still entirely unclear.

Organized and presented by NATURE, the international journal of science

Perhaps the most important international conference you could attend in 1984. Devoted to the recent contributions of molecular biology to the understanding of malignant disease.

For Research Scientists and Clinicians

IN SEARCH OF UNDERSTANDING...

THE MOLECULAR BIOLOGY OF CANCER

This is why NATURE has chosen to devote its third international conference to an occasion when researchers in the life sciences and clinicians can assess the importance of recent developments in molecular biology for the understanding and, ultimately, for the treatment of cancer.

SEPTEMBER 10, 11, 12, 1984
BOSTON PARK PLAZA HOTEL

Park Plaza at Arlington Street
Boston, MA 02117, U.S.A.

The conference program has been designed for two groups of people – researchers in the life sciences anxious to learn about and discuss the latest developments in the molecular biology of cancer, and physicians who consider that these developments may eventually affect their own work with patients.

Participation in the conference will be restricted so as to provide opportunities for those participating to mix with and to question those responsible for the latest research.

To this end, the leading scientists making formal presentations will also take part in two-hour round table discussions, providing an ample and unusual opportunity for participants to take part in detailed discussions and to make short presentations of their own.

To take part in this important and novel conference, register now and book your rooms (also limited) at the Boston Park Plaza Hotel and Towers.

TO REGISTER FOR THE CONFERENCE: Return the form appearing in this advertisement, with your check, or an authorized purchase order from your organization.

EARLY REGISTRANTS SAVE $50: If your registration and payment is received by July 1, you may deduct $50 from the regular full registration fee of $325. You pay only $275.

THE SETTING: Boston Park Plaza Hotel and Towers, Boston located at Park Plaza and Arlington Street, just off the famous Boston Public Gardens and Common.

ROOM RESERVATIONS: A large block of rooms has been set aside for attendees, but we do suggest that you reserve your accommodations early, to avoid disappointment. Rooms must be reserved directly with the Hotel, at (617) 426-2000, or 800-225-2008, Telex: 710 321 1088. Be certain to mention your participation in the "Nature Conference", to take advantage of these special lower rates: Singles: $70, 80 & 85; Double: $85, 95 & 100.

CONFERENCE DINNER: The Conference dinner will be held on Tuesday evening, September 11th, in the Imperial Ballroom. TO INSURE SEATING AT THE CONFERENCE DINNER, please include your dinner ticket requirements and payment of $25 per person with your Registration.

POSTER SESSIONS: A limited space for posters will be made available. Please write to: Poster Sessions Editor, Nature Publishing Company, 15 E 26 St., N.Y., NY 10010.

RECRUITMENT CENTER: Private meeting rooms and staff will be provided for recruitment executives and scientists to discuss employment opportunities. Contact: Miss Gene Fein, Recruitment Services Manager, Nature Publishing Co., 15 E 26 St., N.Y., NY 10010, (212) 689-5900.

Conference Program
September 10-12, 1984
Boston Park Plaza Hotel

Daily Themes:
DAY 1 - ONCOGENES,
DAY 2 - THE CANCER CELL,
DAY 3 - PROSPECTS/PROBLEMS.

MONDAY, 10 September
Exhibition Viewing: 8:30am — 6:30pm
Recruitment Center: 9:30am — 6:00pm

DAY 1
ONCOGENES AND GROWTH FACTORS — WHAT THEY ARE AND WHAT THEY DO

9:00 — 9:15	**Chairman**
9:15 — 10:00	Oncogenes *R. Weinberg (MIT)*
10:00 — 10:45	Growth factors *M. Sporn (NIH)*
11.15 — 12.00	HTLV *R. Gallo (NIH)*
12.00 — 12.30	Clinician's view *S. Broder (NIH)*
2.00 — 4.00	Round table with morning speakers
4.30 — 5.30	The cancer cell *J. Cairns (Harvard)*

TUESDAY, 11 September
Exhibition Viewing: 8:30am — 6:30pm
Recruitment Center: 8:30am — 6:00pm

DAY 2
THE CANCER CELL — HEREDITARY CANCER, TUMOR PROMOTERS AND CARCINOGENESIS

9.00 — 9.15	**Chairman**
9.15 — 10.00	Gene regulation *P. Leder (Harvard)*
10.00 — 10.45	Hereditary cancer *R. White (Utah)*
11.15 — 12.00	Carcinogens and promoters *I.B. Weinstein (Columbia)*
12.00 — 12.30	Clinician's view *F. Gilbert (Mt Sinai)*
2.00 — 4.00	Round table with morning speakers
4.30 — 5.30	NCI program

WEDNESDAY, 12 September
Exhibition Viewing: 8:30am — 3:00pm
Recruitment Center: 8:30am — 3:00pm

DAY 3
PROSPECTS AND PROBLEMS — DRUG RESISTANCE, MONOCLONAL ANTIBODIES AND NEW DRUGS

9.00 — 9.15	**Chairman**
9.15 — 10.00	Diagnostics and therapeutics *G. Todaro (Oncogen)*
10.00 — 10.45	Immunotoxins *J. Uhr (Texas)*
11.15 — 12.00	Drug resistance *A. Varshavsky (MIT)*
12.00 — 12.30	Clinician's view *J. Gutterman (Houston)*
2.00 — 4.00	Round table with morning speakers
4.00 — 4.45	Prospects
4.45	Closing remarks

TO REGISTER FOR THE CONFERENCE, mail this form with your payment.

Please reserve my place at

The Molecular Biology of CANCER

I wish to reserve _____ Conference Registration(s) in the names of: *(Please print or type)*

_____

and _____ Seats at the Tuesday Evening Dinner in the names of:

_____

Name _____ Title _____

Co./Institution _____

Address _____

City, State, Zip _____

I understand that as a paid conference participant, I may attend all sessions, and receive all programs and other materials.

My Check for $_____ is enclosed.
Charge My Credit Card as Shown:
☐ AMEX ☐ VISA ☐ MASTERCARD
Credit Card # _____ Expiration date _____

Signature _____

NEW YORK, NY 10010
Phone: (212) 689-5900

SCANNING ELECTRON MICROSCOPY at MICRO 84

MICRO 84 takes place at the Bloomsbury Crest Hotel in London from July 9th to 13th 1984. MICRO is the largest conference and exhibition concerned with all aspects of light and electron microscopy; and any one microscopical technique, such as SEM, can be easily seen in the context of all the other, allied techniques, available. Today, the SEM is very much a microscopist's workhorse and there is a strong SEM theme running through the whole of MICRO. Some symposia are directed specifically to SEM, others have particular lectures which are relevant to SEM, while in still others complementary techniques are discussed. The following list highlights some of these lectures.

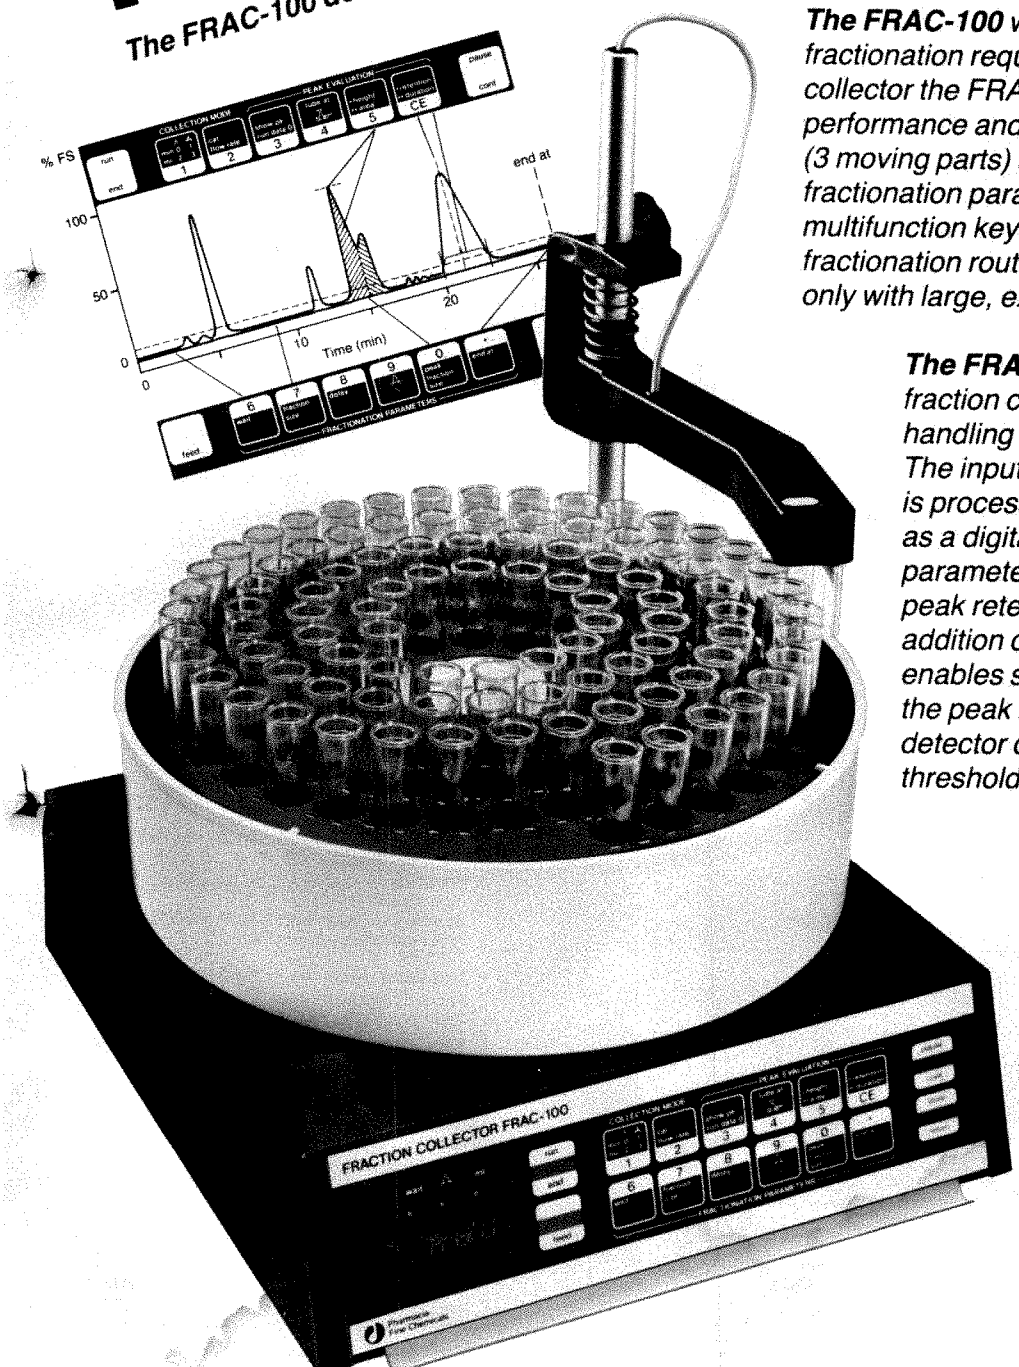
SEM OPIMISATION (Thursday/Friday)	The main objective of this symposium is "Getting the best out of your SEM". A series of tutorial lectures from acknowledged experts will cover the instrument, its operation, specimen preparation, image recording and image interpretation.
TUTORIALS IN MODERN ASPECTS OF MICROSCOPY (Wednesday)	This Symposium is concerned with microscopy and analysis of solid specimens. The lectures will not only cover SEM methods for the non-expert, but also Quantitative Microscopy, Scanning Optical Microscopy, Acoustic Microscopy, and Atom Probe Analysis.
STATE OF THE ART IN TEM AND STEM (Tuesday)	A series of tutorial lectures will deal with imaging and analysis of thin specimens. Among other things, the symposium is intended to update the knowledge of those not working directly with TEM or STEM.
ANALYSIS IN THE SEM (Friday)	In the sessions on X-ray microanalysis and cryo-techniques a number of the presentations specifically deal with preparation of specimens, including by low temperature methods, and their analysis in SEMs.
IMAGE RECORDING (Wednesday)	The symposium will include lectures on optimisation of scanning images, electronic processing of images, and photographic recording of images.
APPLICATION OF SEM (Throughout MICRO)	Throughout MICRO, many of the sessions will include lectures on applications of the SEM to structural observations and microanalysis. Topics including an SEM component include: interfaces in semi-conductors; automated SEM in environmental studies; automatic SEM particle analysis in forensic science; SEM in the study of ancient materials.
EXHIBITION (Throughout MICRO)	It is expected that more than 50 companies will be exhibiting their latest microscopes and ancillary equipment, covering the complete spectrum of instruments and techniques including, of course, full representation of SEM equipment.

Details of the MICRO 84 programme, and further information, are available from:-

The Administrator, Royal Microscopical Society, 37/38 St Clements, OXFORD OX4 1AJ. Telephone: (0865) 248768/721081

Thank you Zoological Record Online for giving me the answers

When I needed information for the head of our zoology department, I found out that **Zoological Record Online** is comprehensive, user friendly, and flexible! It provides access to over 160,000 bibliographic references, making it the world's most comprehensive zoological data base.



Did YOU know that **ZR Online** is marketed, supported and provided by BioSciences Information Service (BIOSIS)? The BIOSIS policy of *free* training courses, *free* newsletters, and *free* search advice has been extended to **ZR Online**. For more information contact BIOSIS on their 800 number: 800/523-4806 (continental USA except PA) or write them. **ZR Online** is currently available through the DIALOG Information Services.

BIOSIS • 2100 ARCH STREET • PHILADELPHIA, PA 19103 • USA • 215/587-4800

The FRAC-100 Fraction Collector

The FRAC-100 does what any other small fraction collector does – collects fractions, PLUS...

The FRAC-100 *will fulfil all your needs for basic fractionation requirements. As a conventional collector the FRAC-100 is unequaled in performance and reliability. Simplicity in design (3 moving parts) and control (flexible fractionation parameters accessed by a multifunction key board) accomplish fractionation routines previously attainable only with large, expensive instruments.*

The FRAC-100, *as a sophisticated fraction collector presents unique data handling and integration capabilities. The input of a 0–10 mV detector signal is processed by the FRAC-100 to report as a digital display such separation parameters as peak height, peak width, peak retention and peak area. The addition of a PSV-100 solenoid valve enables selective fractionation of only the peak material as judged by a slope detector defined by a programmable threshold value.*

The FRAC-100 – as a small, simple inexpensive fraction collector – your best choice, – as a small sophisticated inexpensive collector, far beyond anything presently available – your only choice.

Handbook of Experimental Pharmacology

Editorial Board: **G. V. R. Born, A. Farah, H. Herken, A. D. Welch**

The **Handbook** provides critical and comprehensive discussions of the most significant areas of pharmacological research, written by leading international authorities. Each volume in the series represents the most informative and contemporary account of its subject available.

Vol. 60: **Pyretics and Antipyretics**
Editor: A.S. Milton

Vol. 61: **Chemotherapy of Viral Infections**
Editors: P.E. Came, L.A. Caliguiri

Vol. 62: **Aminoglycoside Antibiotics**
Editors: H. Umezawa, I.R. Hooper

Vol. 63: **Allergic Reactions to Drugs**
Editors: A.L. de Weck, H. Bundgaard

Vol. 64: **Inhibition of Folate Metabolism in Chemotherapy**
Editor: G.H. Hitchings

Vol. 65: **Teratogenesis and Reproductive Toxicology**
Editors: E.M. Johnson, D.M. Kochhar

Vol. 66: **Glucagon I & II**
Editor: P.J. Lefèbvre

Vol. 67: **Antibiotics I & II**
Editors: A.L. Demain, N.A. Solomon

Vol. 68: **Antimalarial Drugs I & II**
Editors: W. Peters, W.H.G. Richards

Vol. 69: **Pharmacology of the Eye**
Editor: M.L. Sears

Vol. 70: **Pharmacology of Intestinal Permeation I & II**
Editor: T.Z. Csáky

Vol. 71: **Interferons and Their Applications**
Editors: P.E. Came, W.A. Carter

Vol. 72: **Antitumor Drug Resistance**
Editors: B.W. Fox, M. Fox

Vol. 73: **Radiocontrast Agents**
Editor: M. Sovak

Planning for next year's summit

Last weekend's London summit was not pointless. And the working group on high technology should seize the opportunities for building a rational framework for innovation.

THE conventional wisdom is that last week's meeting of the heads of government of the seven principal industrialized nations accomplished nothing, which is inevitable. If 4,000 journalists are sent from all over the world to write about a meeting whose proceedings take place in private, frustration and boredom will ensure that no other conclusion will be reached. The nine previous summit meetings were in this respect no different from last week's in London. If those involved are concerned that they are so persistently misunderstood, they have one simple remedy — to hold their private meetings privately, without saying in advance where or when. Then, people's expectations would not be magnified to the point at which they can only be disappointed.

On this occasion, for what it is worth, three substantial benefits have accrued in the eyes of those began by expecting nothing, the chief of which is what the meeting had to say about the management of international debt. The issue is neither arcane nor academic. Increasingly during the past two years, it has become plain that the economic health of all the industrialized nations would be seriously if temporarily damaged if a substantial part of the international monetary system should collapse under the present strain. But why should it matter to people in comfortable industrialized countries, whose chief interest may be the pursuit of some interesting line of enquiry in research, that some distant government should be bankrupt? Surely only a few commercial banks will suffer? That is only half the truth. The Western commercial banks, profit-making and privately held enterprises though they may be, are an essential part of the economic system. And they fall like dominoes, as the events of the 1930s showed all too clearly. The default of a government on its loans, or the collapse of part of the banking system for that reason or some other, would be tantamount to a deflationary impulse within the economy of the industrialized West that would certainly snuff out the fitful economic recovery and might well be worse. The pursuit of research objectives of all kinds would be impeded.

Gloom

Last week's summit acknowledged the truth of this gloomy outlook, which is a good sign. The final communique goes one step further, and says explicitly that the seven major governments will use their influence with their commercial banks to help other governments that "are themselves making successful efforts to improve their position" to pay their debts, chiefly by giving them more time to pay. This is a step forward, but a small step. Better would have been a firm declaration on the size of the United States deficit, which is a cause of high international interest rates because it is not matched by private domestic saving. (Japanese governments can safely run huge deficits because thrifty Japanese, saving for their retirement, forgo current consumption to help out their government.) The statement earlier this week by the new government of Argentina that it had not so far agreed with the International Monetary Fund on a programme of austerity, which is how the summit governments would have it "take steps" to improve its position, suggests in any case that what is now proposed will not work. Politically, the industrialized nations cannot let a newly elected government in Latin America go to the wall, but the commercial banking system could not absorb the debts which it has piled up. On this crucial issue, the summit accomplished something, but probably too little.

On East-West relations — and arms control particularly — the summit declaration is more encouraging. What seems to have been agreed is that the seven members differ in their eagerness to resume negotiations of some kind with the Soviet Union — and have been given the assurance of the others that, up to a point, to do so will not count as rank disloyalty. The result, inevitably, is that governments other than that of the United States will be trying their luck in Moscow in three months ahead. President François Mitterrand, indeed, announced immediately after the summit meeting that he will be off late in the month. By coincidence, the Pugwash organization came to the conclusion, at its Geneva meeting at the beginning of the month, that this was precisely a period when explorations of what might be done on the limitation of nuclear arms would be more productive than formal negotiations. Part of the explanation is that the United States will soon be in the thick of an election campaign. But that, by itself, is no reason why President Reagan should not bring forward the Threshold Test-Ban Treaty for ratification (see *Nature* 7 June, p.482).

Innovation

The third respect in which last week's meeting deserves at least lukewarm applause is that a gathering concerned chiefly with the world's economy found time to approve, if only formally, a report from the Working Group on Technology, Growth and Employment (see p.572). The credit for that goes to President Mitterrand who, in the days of of M. Pierre Chevènement, then the French minister for research, startled the Versailles summit two years ago with his passionate advocacy of technological innovation as the engine of the modern economic system — and as the best way of solving more immediate problems. And while the habit of listening politely to what the working group has to say may be a pale shadow of the Mitterrand evangelism of two years ago, by accident the summit members seem to have created the essence of an institution that could yet render invaluable service to them and the rest of us. Much will depend on what happens in the months ahead.

The working group, although a creature of the member governments, is mercifully above the political battles in which most of them are habitually engaged. No doubt that will remain the case so long as the group is not drawn into arguments about the rights and wrongs of monetarist as distinct from Keynesian economics, or other contentious matters of that kind. Its first instincts, exercised in the preparations for last year's summit at Williamsburg, were to encourage member governments to take the lead in collaborative technical projects (eighteeen altogether).

Gingerly, it has now gone so far as to refer to some of the ways in which the governments which are collectively its master make things needlessly difficult for themselves by their imposition of restraints on technology. This year's topics are the restraints on the free flow of information ordained by strategic considerations (chiefly in the United States) and the tendency of all governments to believe that they too can excel at everything provided they deny themselves and their industries the benefits of technologies developed elsewhere, sometimes by tariffs, sometimes by other means. While the working group's report does little more than define these problems, is has in the process won for itself a chance to contribute to their solution. ▶

This is why it is not too soon to begin preparing the group's report for next year's summit. The most urgent need is that governments should be made to understand the benefits of genuinely free trade in technology, a principle too often illegally denied even within the framework of organizations such as the European Community. Directly or indirectly, all the governments represented in London last weekend are in the business of supporting technological innovation, always by some device for making sure that public purchasing of high-technology products should benefit domestic producers. The immediate consequence is always to postpone a true division of labour in high-technology products, but in the long run, as water finds its own level, it is discovered that it is best, and most economical, for people to manufacture only those parts of products which they can make most economically. Meanwhile, for as long as this truth can be concealed, everybody loses.

The psychological trick that the working group should aim to engineer in preparation for next year's summit is that of persuading member governments that not all of them can be the world's sole supplier of, say, telecommunications equipment or of biologically engineered pharmaceuticals, but that these (and other) technologies are promising enough to allow everybody a sizeable share of a huge cake. That task will not be accomplished by rhetoric alone, for which reason there is an urgent need that the working group's next report should be soundly based in careful analysis and research. In passing, the working group might earn itself some extra credit by securing some practical recommendations on how to save effort in high-energy physics or planetary exploration (see p.573) by sensible collaboration between governments. The group's existence may be fortuitous, but the opportunities in its grasp would not otherwise easily be created. Let us hope it seizes them. □

Postscripts on India

The letters on Indian science on p.578 are the first of a flood. They deserve a careful reading.

WHEN the issue of *Nature* concerned with the condition of science in India appeared on 12 April, the troubles in the Punjab had been rumbling away for at least a year. They have since, as the world knows, exploded at Amritsar, and everybody's concern is that the largest true democracy ever will survive intact. Indians are always rightly saying that many of their apparently built-in obstacles to efficiency and effectiveness derive from their seemingly perverse attachment to democratic ways. The view that the maintenance of that condition of civility is more important than efficient public administration cannot easily be denied, although it is remarkable and courageous that India, with all its social problems, should have kept to that ideal.

The comments which now appear on the survey of the condition of Indian science (and earlier correspondence on the subject) should be read against this background. Some of the more obvious features of the Indian way of running academic and scientific institutions, open access at the universities for example, are largely consequences of the attachment to democracy. (And there is no reason why a state with more than 700 million people should not have more than 140 universities.) But when times are peaceful, there are good reasons why attention should more seriously be paid to the principles of good administration in these institutions. Laboratory directors and vice-chancellors need more freedom to direct their institutions; their colleagues and their students need more tangible goals on which to pin their ambitions. The huge scientific community could itself do much to improve the standards to which the majority work — and there are signs that such a movement is under way.

The question why India needs a scientific enterprise on such a scale, when there is all that poverty (and now Amritsar) needs only the simplest of answers. It has paid off, and handsomely. What is called the Green Revolution is a direct consequence of the investment there has been in India in agricultural research over the past few decades. □

Solar System unknown

A modest case for collaborative exploration of the Solar System deserves cautious support.

THE intended planetary explorers of the United States and Europe are well on the way to breaking records for advance planning (see p.573). Their proposals for a series of collaborative projects would, if accepted, put a cap on planetary exploration between now and the end of the century, at least so far as the industrialized West is concerned. (The Soviet Union and Japan, and perhaps other entrants to this expensive way of gathering data about the Solar System, may yet have surprises up their sleeves.) By comparison, even those who build accelerators are fleet of foot, counting themselves unlucky if they spend more than six years in building a new, more powerful machine. The reason why planetary projects are so long in gestation is that each of them is based on a purpose-built space vehicle packed with an array of instruments, most of which must be specially designed and developed afresh for each intended mission. Costs are also high — $500 million seems to be the standard planning unit. So the question inevitably arises whether there is not some simpler and cheaper way of gathering the same kinds of data. Precisely that question has prompted the US National Aeronautics and Space Administration (NASA) to design a series of modular spacecraft for future planetary exploration.

Within the terms of reference of the joint US–European study, the report now published is nevertheless as sensible as could be expected. Its hallmark is indeed its modesty. One of the assumptions is that the programmes of planetary exploration planned separately by NASA and by the European Space Agency (ESA) will continue, and that the objective of collaboration between the two continents should be to mount projects that are unlikely otherwise to be carried out, yet which together do not carry spending on either side of the Atlantic above the limits likely to be found tolerable. Plaintively, the report says at one point that it would be easy to add to the list of explorations now proposed (to Saturn, six asteroids and Mars) if only there were funds available. The sad truth is that there is unlikely to be unforeseen growth in the budgets, and that the US commitment to the development of a space station (noncommittally endorsed by last week's summit meeting) is likely to take up any slack that may emerge. For the time being, at least, planetary exploration will be a poor cousin to the other projects in the two agencies' portfolios.

While the cost of these space missions is necessarily high, the more serious difficulty for those who would see more spending in this field is conceptual. Once a decision has been made to launch a spacecraft towards, say, Saturn, it becomes impossible not to pack the vehicle with a whole array of instruments devised to glean information about several unrelated phenomena. The result is that these enterprises take on the character of expeditions to distant places of the kind mounted by terrestrial explorers in the nineteenth century. Two of the projects now suggested (to the asteroids and to Mars) have the further disadvantage that they are meant as spurs to the development of new technology (solar-electric propulsion and robotized exploration), further clouding the objectives. It would, however, be a shame if European planetologists have to twiddle their thumbs for the next decade and a half, brooding over the meagre harvest of data ESA plans to provide. If the worst comes to the worst, at least the Saturn project should be mounted.

Meanwhile, planetary explorers should bend their minds to two other tasks, one technical and one conceptual. The case for planetary exploration would carry more conviction if space probes were simpler, cheaper but also faster — having to plan now to make observations more than a decade hence is to be bound to an inflexible chariot-wheel. And it would also strengthen the planetologists' case if they were to list the questions about the Solar System that need most urgently to be answered and then to specify the data that most directly bear on them. Part of the trouble now is that the questions they are asking are not pointed enough to justify spending in lumps of $500 million. □

UK higher education

Cheers but no extra funds for engineering

THE British Government's ambition to redirect higher education towards engineering and physical science has been at least temporarily set back. At a meeting last week (4 June) called by Sir Keith Joseph, Secretary of State for Education and Science, it became plain that other spending ministries were not prepared to contribute by a reduction of their own budgets towards the cost of what the government is proposing.

There is particular resentment among officials of the Department of Education and Science that the Department of Trade and Industry, the chief agitator within the government for an increased output of graduates in engineering and physical science from British universities and polytechnics, was in the event unwilling to back its rhetoric by an agreement that funds should be diverted from its own budget for a new investment in higher education.

Last week, Sir Keith Joseph was asking for an extra £400 million to be spent over the next several years in universities and polytechnics, chiefly on new buildings and equipment for engineering and physical science departments. The government appears to have been convinced that such a development is urgently necessary by the well publicized complaints by engineering companies that they are having to recruit high-technology specialists from overseas and by evidence from within the educational system that the provision of buildings and equipment has for several years fallen short of needs.

In Whitehall, the plan to redirect resources towards engineering and physical science education has for several months been known as "The Switch", in retrospect a galling echo of the title of the 1970s film about confidence trickery, "The Sting". The objective has been to engineer a decisive and, with luck, permanent shift in British higher education towards the preparation of students for work in high-technology industry. The estimated cost of £400 million is predicated on the assumption that it would be better to strengthen and enlarge departments which are already strong (and fully stretched) than to take up unused capacity at other institutions.

Even so, one of the surprises of last week's meeting (attended both by Mr Norman Tebbit, Secretary of State at the Department of Trade and Industry, and by Mr Nicholas Ridley, Financial Secretary to the Treasury, the man who administers public spending) is that the estimated cost of £400 million seems not to have been questioned. It is not at this stage clear whether the extra investment in engineering education would have been accompanied by an increase of student numbers at British universities.

While the meeting seems unanimously to have denied Sir Keith contributions towards his £400 million, the spending ministries represented at the meeting seem to have been less niggardly with their promise of wholehearted support for what he is trying to accomplish. But his direct request to the Treasury for the extra funds seems to have been met with the familiar statement that "further study" would be necessary.

With time unexpectedly on their hands, Sir Keith and Mr Tebbit appear to have fallen into a desultory and even nostalgic conversation about the advantages there would be if only UK students were able to finance their own residence at universities. Schemes for replacing government maintenance grants by student loans, fashionable at the beginning of the present government's spell of office, have long since been abandoned because they offer no immediate relief to the public treasury.

The chance that the Treasury may find part of the funds needed to engineer The Switch in time for the financial year beginning in April 1985 is nevertheless not identical with zero. But many educationists are relieved that the plan has for the time being been derailed, if only because British higher education institutions are still in the thick of adjusting to straitened budgets — and bracing themselves for the probable erosion of the boundary between universities and ploytechnics. Even so, in the aftermath of Sir Keith Joseph's failure with his begging-bowl, the University Grants Committee is likely to be devising a system of carrots and sticks to persuade universities towards engineering education. □

The year 2000

Prophets of doom rejected

Washington

A BLISTERING riposte to the pessimistic forecasts contained in the Carter Administration's 1980 *Global 2000 Report to the President*, was unveiled in Washington last week by the Heritage Foundation. *The Resourceful Earth*, a new book coedited by the late Herman Kahn and a Heritage Foundation economist, Julian Simon, says the *Global 2000* study is full of factual errors and illogical and misleading arguments. The book says the *Global 2000* warning that by the year 2000 the world will be more crowded, more polluted and less stable ecologically is "dead wrong". Its own happy prognosis is that the world in 2000 will be less crowded (though more populated), less polluted and more stable ecologically.

The Resourceful Earth concedes that the Earth's population will grow by the year 2000, but argues that better housing and mobility will make life less crowded for most people. In the richer countries, it says, there is evidence that hazardous air pollution has been declining and water quality improving. In rich and poor countries alike, life expectancy is increasing and average income has risen. Acid rain, the book says, is troubling, but could be mitigated by a greater reliance on nuclear energy. And the prospect of running out of energy, given the availability of nuclear power, is "purely a bogeyman".

The body of *The Resourceful Earth* consists of a score of papers examining trends in population, agriculture, climatic trends, energy, health and the environment. According to Simon, many of the authors were incensed by the "bad science" of *Global 2000* and were determined to put the record straight. Although almost all the papers are robustly optimistic, the introduction (which appears under the names of Simon and Kahn although Kahn apparently died before he was able to make a significant contribution), warns against complacency. It concedes that all is not well everywhere and that a better future will not happen automatically or without effort.

Why the stark differences between *Global 2000* and *The Resourceful Earth*? Mainly, says Simon, because the report to the President failed to use enough trend data and, when it did, used them badly. Thus *Global 2000*, analysing data up to 1975, predicted continuing stagnation in the size of the fish catch. *The Resourceful Earth* claims that data for the years since 1975 show the fish catch resuming its long-run upward trend.

If there is one thread of pessimism in *The Resourceful Earth* it has to do with people rather than nature. Several papers complain that science and ingenuity offer ready solutions to many of our problems but humans and their institutions have a habit of botching them. A persistent example offered in the book is the reluctance of Americans to embrace nuclear power. In a dissenting statement at the end of the book, one author, University of Pittsburgh physicist Bernard Cohen, says he cannot share the optimism of his fellow authors because science has come under "irrational attack by the forces of ignorance". Public fear of nuclear power, he argues, is the fault of the media, "a group of scientific illiterates drunk with power, heavily influenced by irrelevant political ideologies".

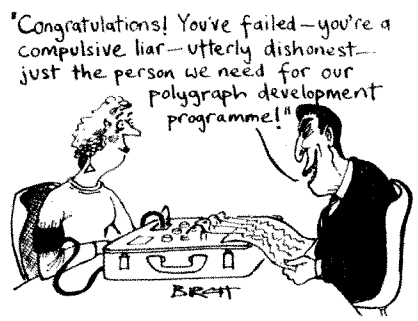
Peter David

The Resourceful Earth: A Response to Global 2000 will be published in July by Basil Blackwell.

British polygraphology

Getting into business

THE polygraph or lie detector has arrived in Britain. A recently established company, Polygraph Security Services Ltd, now offers polygraph tests as a means of combating employee theft, and boasts that in at least one case now pending, charges of theft have been brought after "identification" of a suspect with the polygraph. In another instance, a man who failed a polygraph test was later found to have previous undeclared convictions for theft and was consequently dismissed.



Directors of Polygraph Security Services recently appeared before the House of Commons Select Committee on Employment, which is conducting an inquiry into the implications of the polygraph for industrial relations. The company declined to identify its clients to the Commons committee, citing commercial confidentiality. The committee accordingly threatened to use its legal powers to obtain such information, and the company's directors are now taking legal advice.

The chairman of Polygraph Security Services is Sir George Terry, a former chief constable of Sussex police. The other directors are Mr Jeremy Barrett, Mr Philip Tite and Mr Martin Seligson. Tite and Seligson are directors of Triangle PD Ltd, a printing and publicity company, and Seligson is also a director of Beneficial Arts Ltd, a company which distributes films of horse races to social clubs for fund-raising events. Barrett is director of a market consultancy company. None of the directors has previous experience of polygraph tests. Their training has been through the Zonn Corporation in the United States, of which Polygraph Security Services describes itself as the United Kingdom extension.

Seligson claims that with the polygraph, companies can cut employee theft by 80 per cent. Some client companies are already conducting tests on job applicants, and an existing workforce can be screened regularly through the "honesty maintenance programme" offered by Polygraph Security Services. Seligson stresses that all tests are voluntary, although it is unclear how such a screening programme could possibly be effective if a substantial proportion of the target group declines to be tested.

Seligson is unimpressed by the serious questions that have been raised about the reliability and efficacy of the polygraph. He says that Professor David Lykken, who wrote a critical article on polygraphic interrogation published in *Nature* in February (**307**, 681; 1984) is "totally debunked" and "generally discredited". The authority for this judgement is a paper by D.C. Raskin and J.A. Podlesny published in the *Psychological Bulletin* in 1979 (**86**, 54–59). The empirical issues separating those authors from Lykken boil down to what sort of data is valid for an objective test of the polygraph's effectiveness. Lykken charges that Raskin relies on studies using pre-selected polygraph traces which had previously been scored "correctly" by a polygraph examiner, so providing evidence only that trained polygraphers tend to concur in their judgements.

UK polygraphers are not above circulating (non-attributably) rumours to the effect that Lykken administered or undertook to administer a polygraph test to Mr John de Lorean, now on trial in California, on behalf of de Lorean's defence lawyers. Lykken's version of this story is that the judge in de Lorean's case threw out all polygraph evidence after seeing two directly contradictory polygraph reports: one, from the Federal

Bureau of Investigation, concluded that the accused was deceptive, while the other by Raskin concluded that de Lorean was truthful with 99 per cent probability. Lykken denies ever giving polygraph tests himself except as demonstrations, and says his total involvement with the case was one telephone call.

While Polygraph Security Services is already advertising its services in Britain, little is known about plans to introduce polygraph testing for those employees at the Government Communications Headquarters in Cheltenham who have access to highly classified material. The British Security Commission recommended last year, after a review of the Prime spy scandal, that polygraph testing should be considered for such employees. It is thought that about 20 senior Cheltenham personnel volunteered to take part in a pre-test of the polygraph in London, although some others may have declined. There are no longer any formal links between the majority of employees at the communications headquarters and the civil service unions, but there are not thought to be any immediate plans to extend the test. But, according to one account, it has already been decided in principle to make polygraph tests mandatory for all employees at Cheltenham during their probationary period, and for those with access to highly classified material at each quinquennial security review.

Tim Beardsley

Summit science

Leaders espouse collaboration

THE London summit last week gave an uncontentious blessing to a report of the Working Group on Technology, Growth and Employment — the gathering of senior government science advisers which owes its existence to President François Mitterrand's initiative at the Versailles summit two years ago. But the secret of the report's easy passage seems to have been that its references to contentious issues were cast in the most anodyne language.

On the perennial bone of contention between the United States and the six other summit countries — the control of Western technology by means of the strategic embargo — the report says only that strategic considerations have persuaded governments to seek to control technology and that, "nevertheless", the exchange of information and the encouragement of trade are necessary for the maintenance of technological innovation.

Dr Robin Nicholson, Chief Scientific Adviser at the UK Cabinet Office and *ex officio* chairman of the working group during this calendar year, explained earlier this week that the immediate objective had been to win the acknowledgement of governments that strategically inspired restraints on the free flow of information and products were a potential impediment to the pace of technological innovation. He said that the issue may be explored in greater detail at the two sessions of the group due to take place before the next summit, next year in West Germany.

Other impediments to innovation such as "non-tariff" barriers to international trade are also referred to in the report, which acknowledges that these often stem from the "wish of countries" to be self-sufficient in high technology. Nicholson is especially keen that the working group should encourage uniform and acceptable standards for the new technologies.

The working group's chief initiative since the Williamsburg summit a year ago seems to have been to urge the need for international cooperation on environmental problems, especially acid rain, radioactive waste disposal, the marine environment, the greenhouse effect and development of power sources free of potentially harmful emissions. The working group rejected the notion that these questions should be added to the list of eighteen projects mounted by the time of Williamsburg. Now the summit proper has asked for a detailed report and action plan by the end of this year.

The projects already begun under the auspices of the summit working group are a mixed bag, ranging from thermonuclear fusion, biotechnology and robotics to an attempt to explain people's resistance to new technology (in which the United

Kingdom volunteered to take the lead). According to Nicholson, the robotics projects, led jointly by France and Japan, were a particularly rich source of collaborative research projects, not merely in production technology but in mining, firefighting and agriculture.

The emergence of the working group as an institutional part of preparations for the annual summits of the industrialized nations is something of a surprise. Nicholson explained this week that its objective is largely to identify areas where collaborative research may be useful, whereupon it will be for individual countries to take the lead in fostering particular collaborative projects among summit members. On his view, some of the areas thus identified are certain to be more fruitful than others, while everybody seems reconciled to the notion that some projects will fail for lack of interest.

Even so, Nicholson concedes, there may be a need that the working group should monitor the fate of the projects which its recommendations stimulate. As things are, proprietary information arising in the course of collaborative research projects would remain the property of the partner paying for the research concerned, while information about the conduct of research projects would not necessarily be passed to all interested parties. During the past year, however, it seems to have been agreed that membership of these partnerships should be extended to countries not among the seven summit-going states, with the proviso that outside membership should be allowed when the interests of the project would thereby be served. □

Planetary exploration

Plans for US–Europe launches

A WORKING party of European and US planetary scientists has made a strong bid for a modest layer of frosting on the cake now promised by their respective agencies, the European Space Agency (ESA) and the US National Aeronautics and Space Administration (NASA). The three projects, originally made public at a meeting organized by the working party at Heidelberg in West Germany at the end of April, were put to a meeting of the Royal Society in London last month. But the working group's hope of explicit backing by last weekend's economic summit has not been borne out.

The essence of the recommendations from the joint working group, led by Eugene H. Levy from the University of Arizona and Hugo Fechtig from the Max-Planck-Institut für Kernphysik at Heidelberg, is a set of three planetary missions designed to be complementary to the programmes supported separately by ESA and NASA, and taking account both of Soviet plans (especially for Halley's comet and on Venus) and those being developed in Japan. The projects are:

- A spacecraft bound for orbit about Saturn but releasing *en route* a probe destined to crash on the surface of Titan, the largest satellite of Saturn, measuring atmospheric and aerosol constituents of the atmosphere of Titan on the way. The object would be launched in 1992.
- Exploration of up to half a dozen asteroids would be attempted by means of a spacecraft directed successively to chosen asteroids, spending about a month in orbit about each of them in turn. The feasibility of this project hangs on the development of a solar-electric propulsion system. Recommended launch date is 1994.
- The most ambitious project is a plan to put an automatic vehicle on the surface of Mars for the collection of geochemical and geological data. Both the landing craft and the vehicle would present considerable technical challenges to those working on the project, for which no launch date has been set except that it should be before the end of the century.

The projects singled out by the working group for priority were originally chosen so as to provide opportunities for a measure of independent collaboration in which respective US and European halves would be developed and built independently. The working group says that the first two projects could be contained within the budgets now foreseen for planetary exploration by NASA ($300 million a year) and by ESA, but that the third, perhaps the joker in the pack, would require that extra funds should be set aside.

The working group report emphasized that the three projects are intended to be complementary to the existing planetary programmes of the two agencies. NASA's future strategy is now tied to the development of a series of modular low-cost spacecraft that would be launched from the shuttle by a Centaur rocket. ESA's programme depends on the use of Ariane. The working group also draws attention to opportunities for closer coordination between the existing plans of the two agencies, the coordinated launching of the US and European Martian satellites due to be launched in 1990.

The working group was established jointly by the European Science Foundation and the Space Sciences Board of the US National Academy of Sciences, each of which has endorsed the recommendations. The test of its success will, however, lie with the responses of the operating agencies, NASA and ESA. The former plans in the next several years to concentrate on the development of low-cost planetary exploration as part of its Observer programme, while European planetologists grumble that they are poor cousins to the astronomers in ESA's forward planning. □

Indian nuclear power

Breeder not so fast

New Delhi

THE Indian Atomic Energy Commission has announced that a tiny reactor using uranium-233 as fuel has become critical at the Bhabha Atomic Research Centre (BARC) at Trombay. This is cheering news at a time when the nuclear power programme is under fire for time and cost overruns in commissioning nuclear reactors, frequent breakdowns and a meagre output of the necessary heavy water despite investment.

The reactor concerned is the only operational reactor in the world fuelled by uranium-233, a man-made fissile isotope of uranium produced by irradiation of thorium in a reactor. The fuel has been produced BARC using a research reactor and reprocessing plant.

For India, the importance of the development lies in its long-term nuclear power programme which is to be based on conversion of thorium to uranium-233. BARC has now shown that this may be feasible. The southern Indian states of Kerala and Orissa have deposits of thorium large enough to sustain atomic power generation for more than a hundred years. Eventually, reactors with uranium-233 fuel may be used as a basis for a fuel cycle which breeds new fissile material.

The tiny reactor Kamini developed at Trombay, uses about 500 grams of uranium-233, and will be commissioned at Kalpakkam research centre near Madras in the next three months. It is estimated that even a test reactor will have to be 100 times bigger than Kamini. Meanwhile, a 15 MW test breeder is nearing completion at Kalpakkam. Indian scientists have developed plutonium-uranium oxide fuel for this reactor. France was to have supplied the fuel, but the deal has fallen through because of what India calls the "prohibitive price" demanded by France.

India's second phase of atomic power development is based on the fast breeder system. Feasibility studies and a design are nearing completion for a 500 MW sodium-cooled reactor to be set up in the next decade. The reactors in the first stage are based on pressurized heavy water and indigenous natural uranium. Only the Tarapur plant is using the enriched uranium now being supplied by France.

India has set a target of 10,000 MW for its nuclear power capacity at the turn of the century, which would meet 10 per cent of the expected total power requirements. Five projects are already in operation, with a nominal capacity of 2,240 MW, and two more under construction will add another 510 MW. But, with a gestation period of as much as 10 years, there are doubts about whether India will meet the ambitious 10,000 MW target. **Sunil Saraf**

US agricultural research

Congress digs in heels

Washington

HOPES for an expanded programme of competitive grants for agriculture have been dashed once again by Representative Jamie Whitten (Democrat, Mississippi), chairman of the powerful House of Representatives Appropriations Committee. Last week, the House went along with Whitten's wishes, approving major cuts that his committee had made in the Reagan Administration's request of $50 million for the programme. The new initiative in biotechnology under the programme was cut from $28.5 million to $10 million. Plant science was cut to half of its present level of $15 million (also the amount requested for next year). Also missing from this year's $34,000 million agriculture budget is $5 million approved last year for graduate fellowships.

Representative George Brown, who has been fighting year after year to increase support for competitive grants above the $17 million level where it has stagnated since its inception in 1978, offered an amendment on the floor of the House to restore $10 million of the cuts to biotechnology. The amendment was rejected on a voice vote. According to Brown's staff, there was little hope that the amendment would be passed ("no-one bucks the chairman"), but Brown believed he had made his point and may have garnered some quiet support that will help when the bill goes to House–Senate conference. The Senate, which has yet to act, is likely to agree with the full administration request.

Supporters of an expanded programme of competitive grants had been optimistic this year. Many longstanding opponents — notably the land-grant colleges, which had tended to view competitive grants as a threat to their assured non-peer-reviewed federal support — have recently changed sides. The association of land-grant colleges produced a report last autumn recommending $70 million for competitive grants for biotechnology and two US Department of Agriculture (USDA) research advisory panels had made similar recommendations. The President's science adviser, Dr George Keyworth, has also lent his personal backing.

During the floor debate, Whitten twice dismissed basic research as "finding answers for answers' sake" and suggested that biotechnology research was "based on hopes" that do not address farmers' immediate needs.

Besides ordering the cuts, Whitten's committee earmarked parts of the competitive grants funds for specific research projects — a development that the programme's supporters say threatens to subvert the principle of investigator-initiated peer-reviewed research. Most of the earmarking clearly reflects the committee's desire to rescue congressional pet projects known as "special grants", scheduled to be phased out this year. USDA has never cared much for special grants, a programme of mandated research that gives the department little flexibility. The special grants programmes in soybean research, acid precipitation and alcohol fuels were transferred in their entirety to the competitive grants plant sciences section, a total of $1.7 million in earmarked funds; two new sections were created in the competitive programme to accommodate $3.5 million in special grants programme on aquaculture, gypsy moths, boll weevil and pine bark beetle; and, apparently for lack of a better place to put it, $250,000 for "sugar cane in Hawaii" was inserted in the biotechnology section. Taking into account the cuts and earmarking, the competitive programme received only an additional $497,000 in unrestricted funds over the current appropriation.

Meanwhile, there are increasing signs that USDA's in-house research arm, the Agricultural Research Service (ARS), is taking biotechnology seriously. Both Beltsville, ARS's chief research centre, and an ARS laboratory in Albany, California, are to become centres for biotechnology. Beltsville officials are speaking of quadrupling research in this area over the coming years. The Albany laboratory will also receive increased support, and collaboration is planned with researchers at the University of California at Davis. Most of the new effort will apparently be supported by a shift of existing funding, since ARS is to receive only a 3 per cent increase in next year's budget.

Stephen Budiansky

Data protection

UK bill improved and approved

THE British Government's Data Protection Bill, substantially modified during its committee and report stages, was finally approved by the House of Commons at its third reading last week. The bill sets out to provide for the first time the statutory right of access for individuals to data that are held about them in machine-readable form, while at the same time preventing unauthorized disclosure of such information. Despite the highly contentious exceptions to these general principles, the official opposition declared itself content with the concessions offered by the government last week and did not oppose the bill, which now returns to the House of Lords. It is expected to gain the Royal Assent within the next month.

One of the most controversial clauses of the bill would have allowed medical data to be passed to outside agencies such as the Inland Revenue or the police by people other than health professionals. A medical inter-professional working group under the chairmanship of Sir Douglas Black has drawn up a code of practice to govern the disclosure of medical information, and after extensive lobbying the government has now accepted that these should in principle apply to computerized health data wherever they occur. A government amendment to the bill will allow the Home Secretary to bring in codes of practice, based on those to be used within the Health Service, wherever these precautions are thought necessary.

Universities and examination boards had been worried that the bill's provisions would allow examination candidates access to their marks even before the examination results were officially published. That anomaly has also been rectified; candidates for examinations will in future be allowed access to their marks only 5 months after the request, or 40 days after the examination results are published, whichever should be sooner. Some university vice-chancellors had, however, hoped that candidates' access would be delayed until 90 days after publication of results, to discourage frivolous challenges to the accuracy of examination data from disgruntled candidates.

Other modifications incorporated during the bill's committee and report stages will allow individuals access to data held about them for the purposes of immigration control, and will allow individuals damaged through inaccurate data the right to compensation for damage and distress. The data protection registrar is to play a more active role than was originally foreseen, promoting codes of practice among data users and pursuing complaints raised by individuals about whom data are held.

Blanket exemption in the bill's earlier version that would have allowed the Home Secretary to exclude any or all government-held data from the bill's disclosure provisions have been considerably curtailed, and small data banks held solely for payroll accounting purposes will not now have to register under the act.

Last week's debate was remarkable for the unaccustomed affability and cordiality displayed between the Home Office minister involved, Mr David Waddington, and the speakers of the official opposition, mainly Mr Robert Kilroy-Silk and Mr Denis Howell. Only Liberal Members of Parliament seemed still determined to score every point they could. It seems that the committee debates on this controversial bill were more than usually productive, and most of its former opponents seem satisfied with the changes that have been made. The bill will allow Britain to ratify the European Convention on Data Protection.

NSF moves

Knapp replaced by Bloch

Washington

DR Edward Knapp, director of the National Science Foundation (NSF) for the past two years, will leave his post at the end of this year to return to Los Alamos. This was announced earlier this week by NSF, which said that Knapp will be succeeded by Erich Bloch, now an IBM vice-president, who has spent all his working life with the company.

Knapp's departure is unexpected. During his spell in Washington, he has secured for NSF some of the most substantial budget increases since the foundation's inception. Over the past two years, the budget has grown by more than 35 per cent while NSF's traditional involvement with science education, virtually eliminated during the early years of the Reagan Administration, has been partially restored.

Knapp has been an energetic and stout defender of the NSF's role in the support of basic science but also a loyal member of the administration. One striking feature of his tenure of his office is that the posts of deputy director and of the three statutory assistant directors at NSF, vacant when he was appointed, have remained unfilled.

Bloch is by background an electrical engineer who, unlike his predecessors, has no doctorate. At IBM, he was responsible for the development of the microprocessors for the IBM 360 series of computers. Since 1968, he has held a number of senior management positions with the company and is at present in charge of technical personnel development.

Bloch was born in Germany in 1925, and became a US citizen in 1959. He is a member of the National Academy of Engineering. The director of NSF is appointed by the US President for a six-year term, which appointment is subject to confirmation by the Senate.

Stephen Budiansky

British nuclear power

BNF bites contamination bullet

BRITISH Nuclear Fuels PLC has announced that it is planning a £100 million study to find ways of reducing radioactive discharges into the Irish Sea to a level as near zero as possible. The decision was announced last week by Mr Con Allday, the company's chairman, who stressed that the new policy was in direct response to public concern about radioactive discharges from its reprocessing plant at Sellafield (formerly Windscale).

Declaring that the company must respond to "fears which are genuinely held, however ill-founded", Mr Allday said BNF would "not attempt to fight a rearguard action on behalf of rationality". The company would recognize the strength of public opinion and would take steps to reduce discharges to "very much lower levels than hitherto planned".

The company has been through a disastrous few months for public relations. Last November, a television documentary drew attention to a locally increased incidence of leukaemia in children near the reprocessing plant at Sellafield and raised the possibility of a link with the plant, which emits Europe's largest routine discharge of radioactivity into the environment. The documentary spurred an urgent inquiry, now in progress, by a team headed by Sir Douglas Black, a former president of the Royal College of Physicians, and formerly Chief Medical Adviser to the Department of Health.

Days later an unplanned discharge of radioactively contaminated chemical solvent led to public warnings from the government to avoid the use of beaches in the area, a warning recently withdrawn. The company's conduct was later criticized in swingeing terms by the Department of the Environment. More recently, transport unions have threatened to block the delivery of spent fuel to the plant unless the levels of discharge are reduced.

Discharges of both beta-gamma emitters and alpha-emitting actinides from the plant are down to a tenth of the peak levels of the early 1970s. Sir Denys Wilkinson, until recently chairman of the government's Radioactive Waste Management Advisory Committee, said last week at a lecture organized by the Science Policy Research Unit of the University of Sussex that radiation dose to critical groups resulting from the Sellafield operations was "higher than one would like it to be". The original fluorescein experiments on which the discharge policy was based were planned and executed in 4 months, Sir Denys recalled. There had been no full evaluation of the consequences of the discharges, and unforeseen developments such as the lowering of plutonium safety limits and the "uncooperative attitude" of the Irish Sea in returning radioisotopes to land instead of dispersing them into the ocean had reduced margins of confidence. In addition, discharges were unnecessarily high in terms of what is easily achievable. Discharges from the French reprocessing plant at Marcoule, for example, were substantially than that at Sellafield. Sir Denys was nevertheless convinced that nobody had suffered any significant extra hazard as a result of British waste disposal practices, and he expressed doubts as to whether Sellafield could achieve the low emissions reached at Marcoule.

The £100 million study now proposed by BNF is above and beyond current action to reduce discharges costing an estimated £150 million. An ion-exchange plant now nearing completion will cut down discharges of radiocaesium, and a separate salt evaporation plant will substantially cut actinide discharges. Further reductions may be brought about by improvements to the reprocessing plant itself.

The recent events at Sellafield have postponed any possibility of a public offering of shares in BNF, which are at present all held by the government. There have also been extensive changes made at senior management level.

The company is still awaiting the decision of the Director of Public Prosecutions on whether criminal proceedings should be started against BNF over November's debacle. Possible infringements of operating licences were afterwards reported by the Nuclear Installations Inspectorate.

Tim Beardsley

IOS closes lab

THE UK Natural Environment Research Council (NERC) has decided that there is a *prima facie* case for closing the Taunton site of the Institute of Oceanographic Sciences (IOS), which carries out research in sedimentation and applied wave mechanics. The council's governing body was due this week to consider the implications of transferring the work to other NERC sites.

Staff at Taunton are unimpressed with the way NERC has handled the matter. The director of IOS, Dr Anthony Laughton, was said to have promised speedy decisions on the future of the site almost a year ago. Dr Laughton declined last week to make any comment about the proposed closure.

Staff at Taunton do not see where they can go. NERC's budgetary problems mean it cannot put up any new buildings, and there is not thought to be room for existing Taunton staff at the IOS site at Bidston on Merseyside. Most would prefer instead to move to the site of the Institute for Marine Environmental Research at Plymouth.

The accommodation problems will probably be solved by the resignation of many of the staff. Scientific manpower at Taunton is already much less than it was in the past; the decreased emphasis on wave power as a likely future renewable energy source may be part of the explanation. Finance from the Department of Energy has been repeatedly delayed, causing difficulties for those planning research. But, in theory at least, research should not be cut back as a consequence of the move now planned.

Tim Beardsley

Correction

THE limit for nitrogen oxides in ambient air proposed in the EEC directive (*Nature* **308**, 309; 1984) should have read 200 gm^{-3} not 200 $mg\,m^{-3}$. □

Mercury pollution

Dry battery alarm in Japan

Tokyo

A PAIR of headphones and a portable cassette player have become pretty much standard street wear for young Tokyoites, but they are creating a new problem for the Japanese Government — how to dispose safely of the batteries that power them. Alkaline-manganese batteries have been favoured because they provide a stable voltage and last a long time: the trouble is that they contain a lot of mercury which, it is feared, is finding its way into the environment from municipal rubbish tips.

The risk of mercury poisoning raises strong emotions in Japan. In 1956 and 1964, major outbreaks of Minamata disease, caused by eating shellfish contaminated by methyl mercury in factory effluent, left thousands of victims, some paralysed from birth.

Public protest over risks from batteries led this week to an announcement of subsidies and tax incentives for industry to set up a special non-profit research and development association to find ways to make mercury-free batteries. This move has, however, neither been welcomed by industry nor been seen as much more than a sop to public opinion by consumer groups. Industrial companies have been trying for years to take the mercury out of batteries — simply because it is so expensive — but without finding a suitable alternative.

Japan is now manufacturing a staggering 2,850 million dry batteries each year. About two thirds of these are for domestic use and the 70 tons of mercury they contain — mainly in the alkaline-manganese batteries and "button" type mercury batteries used in cameras — end up in domestic rubbish, most of which is used in landfill in 2,500 municipally owned sites. According to calculations at the National Institute of Environmental Science, the research arm of the environment agency, these sites will have an average battery-derived mercury content of about three parts per million — a thousand times higher than the maximum mercury content permitted in water supplies — on top of a small amount of mercury from discarded fluorescent lighting tubes and other sources. As the batteries corrode, the mercury will enter the environment and an unknown fraction of it will be converted into organic mercury by bacteria and leached away. Most sites are small and are converted to other uses within five years; being municipally owned, they are often converted to public use, including the building of schools and playgrounds. The risks are much less from the small fraction of rubbish that goes to incinerators rather than to landfill. Incinerator temperatures are far above the boiling point of mercury and the concentration of vapour reduced into the air is low — much lower than the World Health Organization guideline levels although still thousands of times greater than natural background levels.

Consumer groups are now demanding that batteries be collected and disposed of separately from other rubbish. Already about 400 of the nation's 3,300 municipalities have passed local regulations requiring citizens to deposit their used batteries at special disposal centres rather than in household rubbish, and that number is expected to grow to 800 by the end of the year. All the local authorities can do with the batteries at the moment, however, is to store them until some safe disposal method has been found.

Dr Tsukehiro Gotoo, chief researcher at the National Institute of Environmental Science, hopes to see the construction of five battery reprocessing plants across the country together with the enforcement of a refundable deposit system to encourage the return of used batteries. A private battery reprocessing plant is already in operation at Hokkaido but its charges are high — 80,000 yen (£260) per ton of batteries plus transport charges. Studies at the institute show, however, that setting up regional recycling plants with a capacity of 2,000 million batteries a year would at most add only Y10 (£0.3) to the cost of a battery. Such a move seems more likely to provide a practical solution to the problem than the call of the Ministry of International Trade and Industry (MITI) for research on non-mercury batteries. **Alun Anderson**

Radioactive waste

Mongolian alarm at China's plan

CHINESE plans to act as a "nuclear dustbin" for Western countries have provoked a sharp reaction in the neighbouring Mongolian People's Republic. Alarm was crystallized last month in a formal interview, organized by the Soviet news agency TASS and its Mongolian equivalent Montsame, with a Mongolian physicist, Dr D. Dorjbat, who appears to have been selected as a mouthpiece of grass-roots scientific concern.

According to Dorjbat, the Chinese do not possess a highly developed nuclear technology, and so will not be able to ensure a reliable method of storing the wastes. Since they plan to bury them beneath the Gobi Desert, there is a serious risk of contamination of Mongolian as well as Chinese territory, through seepage of radioactive material in the groundwaters.

Dorjbat went on to discuss the political implications of the plan . The Chinese, he alleged, not only hope to obtain additional hard currency from the plan (their preliminary tenders offer to take up to 4,000 tonnes of waste by the end of the century thus earning $6,000 million); they also want to process the waste into plutonium for nuclear weapons. Numerous "foreign experts", he said, have drawn the same conclusion.

Dojbat made no attempt to explain how, at the same time, the technological level of the Chinese could be too low to deal with wastes but high enough to extract plutonium from those wastes. He seemed more at ease with his political statements, alleging that China is at present helping Pakistan to develop nuclear weapons (a claim which the Pakistanis vehemently deny). He also attacked the "disrespect" for the destiny and lives of the Chinese people shown by their leaders who, he claims, regard a nuclear war as winnable.

Beijing, so far, has made no direct reference to the allegations, but appears to be treating them as significant signals in the current war of words with Moscow. Within a few days, *The People's Daily* carried what was clearly a direct refutation of the attacks on the waste disposal plan, affirming that Chinese technology was well-equipped to deal with all forms of nuclear waste, solid, liquid or gas. The more sinister charges that the Western wastes would be used as the raw materials for bombs was, however, pointedly ignored. **Vera Rich**

Moscow visit off

Washington

AMID continuing uncertainty about the health of Soviet physicist Andrei Sakharov and his wife Yelena Bonner, the US National Academy of Sciences confirmed last week that its president had postponed plans to visit the Soviet Union to re-establish formal links with the Soviet Academy of Sciences.

In a short telegram to A.P. Aleksandrov, president of the Soviet Academy, Dr Frank Press, president of the US National Academy, said talks on a new agreement were "impossible" given the deepening concern of American scientists over the circumstances of Dr Sakharov. The telegram added: "I have delayed until the last moment a final decision in the hope that the situation would be positively resolved in a manner that all of us would recognize. Since this hoped-for development has not occurred, I believe it is to our mutual advantage to postpone the visit of our delegation until a climate more favourable for positive discussions exists."

Although academy officials stressed that the decision to cancel the planned visit was taken by the academy alone, they acknowledged that Dr Press had consulted the government. The officials also stressed that the visit had been postponed rather than cancelled, and hinted that it could go ahead if the Soviet Academy showed signs of interceding on behalf of Sakharov and Bonner. Peter David

Nuclear winter

ICSU project hunts for data

AN urgent call for information on the consequences of large ground-based fires for the atmosphere of the Earth has gone out from the workshop held in Leningrad between 14 and 16 May on the climatic and biological consequences of nuclear war. The meeting is part of the programme by which the Scientific Committee on Problems of the Environment (SCOPE) of the International Committee of Scientific Unions (ICSU) proposes to produce a comprehensive report on the subject by September 1985.

Participants at the Leningrad meeting explain that one of the obdurate uncertainties of the prediction of sharply reduced and even sub-zero temperatures on the surface of the Earth after a nuclear war, called the nuclear winter, concerns the likely behaviour and effects of the large amounts of smoke from fires that would be carried into the atmosphere. The aggregation of smoke particles is, in particular, not taken into account in the models of the effect so far published.

At the Leningrad meeting, Soviet scientists suggested that data bearing on this question might be gathered from studies of large Siberian forest fires, to which end a meeting on the subject is to be convened in the Soviet Union, followed by another in West Germany.

The possibility was also canvassed of collecting data from the forest fire that has been raging during the past two years in Indonesia. One difficulty appears to be that the resolution of satellite data, both spatially and in time, may not be sufficient for the model builders. The SCOPE office responsible for the project thinks it would be valuable to have the services of an aircraft to make observations of major fires occurring in the next twelve months, but is not hopeful that it can find the resources.

On the design of climatic models, the Leningrad meeting emphasized the importance of full three-dimensional models of the general circulation taking account of the "scavenging" of particles from the atmosphere. One of the particular difficulties to be surmounted, according to a statement after the Leningrad meeting, is that of accommodating mesoscale (intermediate scale) atmospheric turbulence in the general circulation models.

The reactions of participants at the Leningrad meeting to the general question whether nuclear winter is a probable consequence of a major nuclear exchange appear to be mixed. Some stress the need for more data and better model studies. One Western participant said, however, that he had been impressed that "the nuclear winter is becoming more real all the time". Some claimed to have detected a difference between what they called the Moscow school (represented at Leningrad by V.V. Aleksandrov), and the Leningrad school (K. Ya. Kondrat'ev), with the former being more certain than the latter that a nuclear winter would follow a nuclear war.

The next workshop within the SCOPE project will be held in Paris in October. Drafting of the final report is due to begin at a meeting in Colorado next January, but the final version of the report will be completed only at a meeting of the project team arranged for next June at the University of Essex in the United Kingdom

Part of the problem that lies ahead is financial. Most of the support for the SCOPE project, launched at the Cambridge meeting of ICSU two years ago, consists of a grant of $75,000 from the Rockefeller Brothers' Trust, but other possible sources are being approached. □

AIDS development

NIH to license HTLV

Washington

THE companies selected by the US federal government to manufacture a blood test for acquired immune deficiency syndrome (AIDS) are expected to be announced this week. A scientific panel has already met to review the 20 or so proposals received in response to an announcement in the *Federal Register* on 3 May, and recommendations have been forwarded to Assistant Secretary for Health Edward Brandt.

The selected companies will be provided with Dr Robert Gallo's method for mass-producing human T-cell leukaemia virus III (HTLV-III) in return for a royalty payment to the government that is expected to be 5 per cent. The *Federal Register* announcement specified that applicants should have experience with retroviruses, virus production and the manufacture and distribution of radioimmunoassay kits, and have access to a P-3 containment facility. Although skill in recombinant DNA techniques was also mentioned, members of the scientific panel that reviewed the applications said they gave far greater emphasis to ability to manufacture the product quickly and in large quantity. Millions of test kits will be required each year to screen blood products. It is expected that the initial production will rely exclusively upon existing technology — growing the viruses in bulk to produce enzyme-linked immunoabsorbent antibody (ELISA) tests to detect the virus. This widely used technique provides a sensitive and simple means of assaying serum antigens. Eventually, recombinant DNA techniques may be used to produce virus antigen for the tests.

Abbot, DuPont and Roche are said to have submitted strong proposals. More than one company is expected to be chosen.

Genentech has submitted a proposal through its joint venture with Travenol, Genentech-Travenol Diagnostics. Genentech is also known to be seeking a basic research collaboration with Gallo and perhaps also with the French group at the Pasteur Institute. Gallo is said to be in something of a dilemma over the possibility of collaborating directly with a private company; on the one hand he needs the expertise in gene expression that the private companies have, but he is also concerned about giving preference to one company outside the context of the licensing agreement.

Science in India

The supplement on Indian science Nature *12 April (pp. 581-600) has prompted many reactions. Some are published here, with more next week.*

SIR — The key to considering science and technology in India lies in recognizing that India is trying to go through three revolutions simultaneously — the agricultural (still incomplete), industrial and computer revolutions — with a government that is democratic, a population less than half of which is literate and resources that are hardly adequate for a task never before undertaken. This is the reason for the wide spectrum from poverty to excellence that one finds in India in all aspects of life. I do not think that *Nature*'s supplement recognized this, explicitly at any rate.

A few careless statements crept in — for instance, "India... often describes itself as the third nation in the world of science and technology". The truth is that India does state frequently that it has the third largest scientific manpower, but mainly to illustrate that despite that fact, productivity is low in science, industry and everywhere.

But my main objection is to the way you depicted the central universities as "breeding grounds for violence", apparently on the basis of the report on the working of the central universities. The report has nothing to do with the actual work of the central universities and much less with science in them; rather it is concerned with factors preventing the central universities from working as they ought to. The report is in no way a guide to what the central universities are, any more than a pathologist's report reveals a man's personality.

In fact, the original concern of the report was precisely that of "finding some way to restore authority to where it belongs". For several decades, long before the Indian Institutes of Technology started to blaze their trails, the central universities, notably those of Delhi, Banaras and Aligarh, contributed much to science and humanities. It is totally wrong to say "nepotism, disorder (even violence) and maladministration are rife even in the seven (central) universities...", wherever this information came from.

Your sampling of the scientific institutions and scientists also appears to be inadequate. Unless one is careful, the visible and the vociferous have a high probability of looming large. But surprisingly, after all that is said, you have not given much, except, perhaps, a few more counts in the *Science Citation Index*. Yes, ambivalence seems to be a part of our relations.

But despite these complaints, and although I do not always agree with your conclusions, your survey is the most incisive analysis of the complex system of science in India. I agree with you that "India has by far the best chance of succeeding" in the development of science and technology, not because of "the ingenuity and articulateness of its people", but because, as Aldous Huxley pointed out (*Science and Literature*), one of the greatest achievements of science is to have developed a method independent of those who work with it.

B. S. RAMAKRISHNA
University of Hyderabad, Hyderabad 500 134, India

SIR — You are, of course, right in saying that all is not well in India's Science. But great strides have been made. As our Prime Minister declared during a White House reception, India is engaged in the stupendous task of moving hundreds of millions of people into the twentieth century. Against this backdrop one can understand why our laboratories and classrooms are no longer sheltered. The attendant erosion of academic freedom, loss of objectivity and so on are inevitable, but, one expects, temporary phenomena.

Notwithstanding the problems, there have been some achievements (as noted by you also). The green revolution is a reality, and our chemical industry is able to lean on our own research and development. Where high technology is concerned, we can certainly claim we know how to launch a satellite and how to build a nuclear power station. On the more exotic basic research side, we cannot boast of a string of spectacular discoveries, but then our total investment relative to that in the West is paltry. If achievement is measured relative to obstacles overcome, our record measures up favourably to those of others.

All the same, we are neither satisfied nor complacent. Recently our two academies held a joint brainstorming session to examine how to improve matters. It was discovered (as expected) that streamlining Indian science was about as easy as holding a plasma at a million degrees in a container at laboratory temperature, and for essentially the same sort of reason. But some suggestions did emerge and they have been transmitted to the Science Advisory Committee to the Cabinet.

We are confident we will make it and are working hard towards that objective. As you remark, "the doubt is not whether but when". Meanwhile, our expatriate friends could note that Indian science cannot be bettered by simply asking "Is this all we have done . . .?" (Incidentally, what have those giving this advice done for us?) Nor will it be accomplished by listening to seminars by scientists coming for a family reunion or even under the auspices of an international committee.

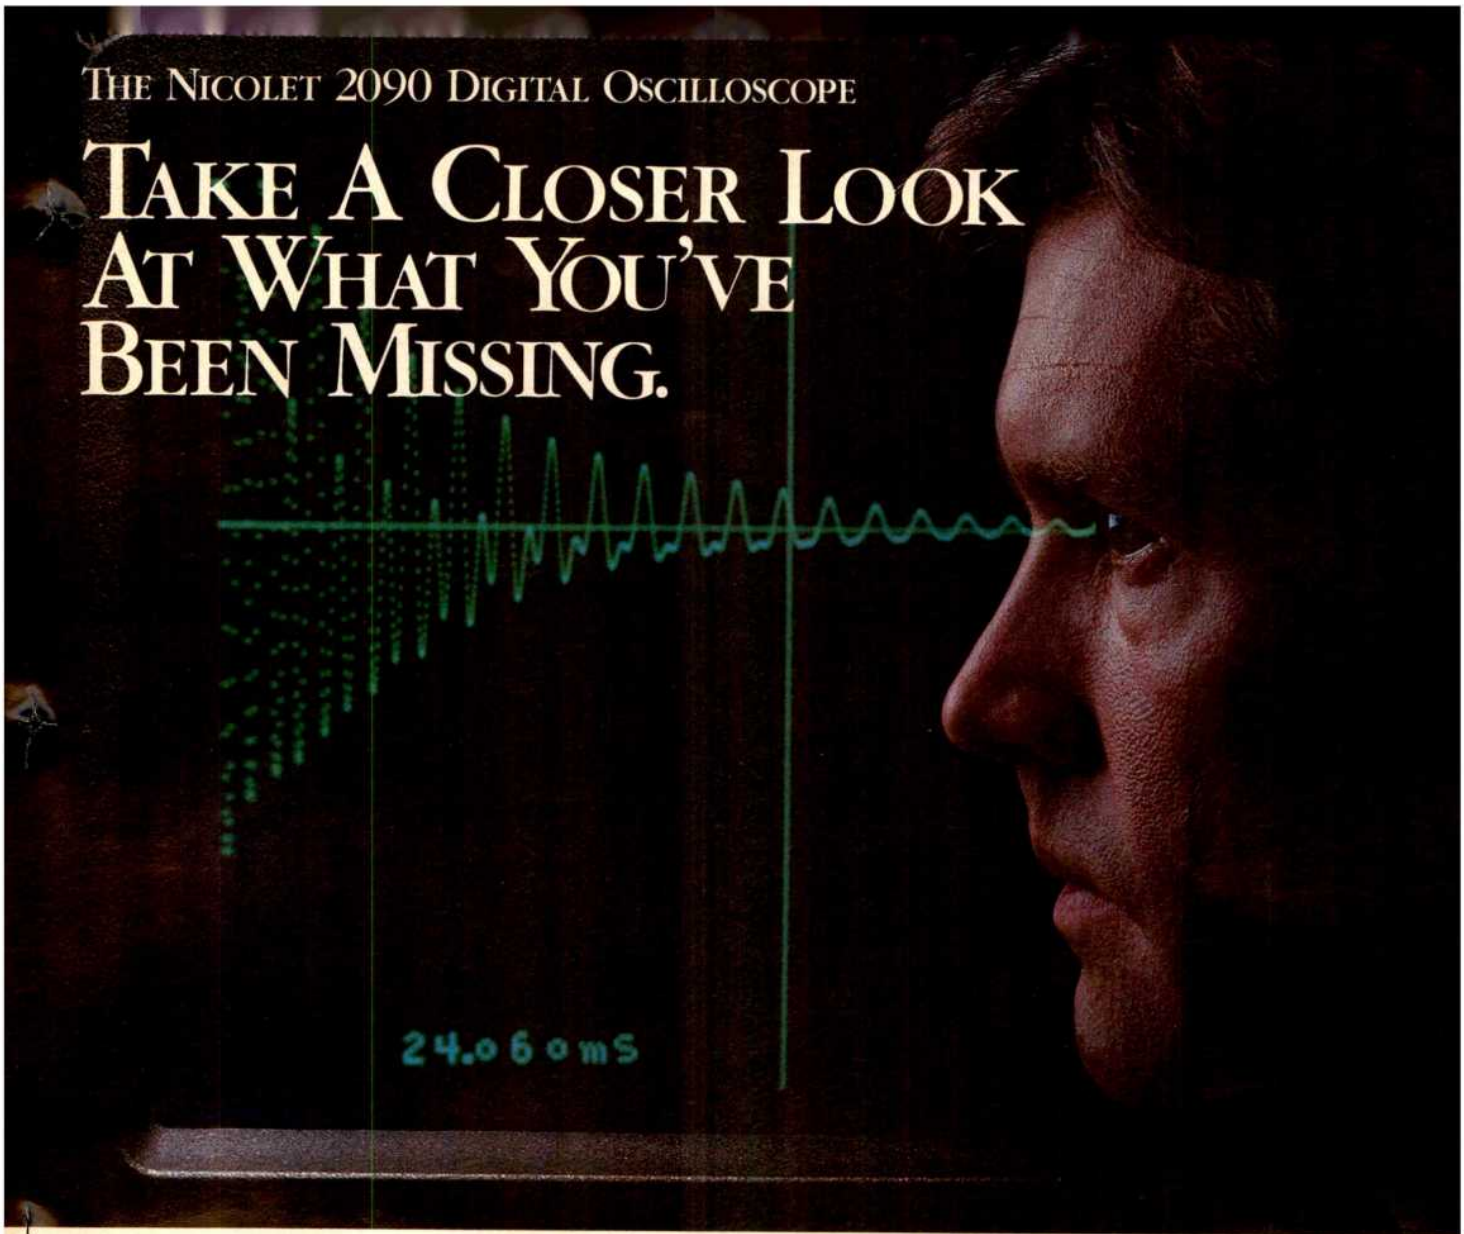
G. VENKATARAMAN
Reactor Research Centre, Kalpakkam 603 102, India

SIR — Readers of your survey are likely to conclude that most of what is good and worthy of its name in Indian science is so because (1) a director or a chairman or perhaps a minister knows and means his/her business; (2) they or their organizations have or at least had good overseas connections and (3) they have somehow managed to avoid the anything-but-beautiful influence of the run-of-the-mill scientific workers and of the people at large.

The major contradiction in Indian science is that of its patch excellence *vis-à-vis* its unrootedness in Indian soil. Co-operation from scientifically advanced countries is necessary and should be welcomed. India neeeds to ensure a certain degree of immunity against the crisis, of which there are visible signs, by directing science in international directions. But the country also needs help in promoting the search for identity of the "two Indias".

With the general elections expected this year, the political undertone of the report carries significance. However "surprising" and "dangerous" it may be for Indian science to be strongly influenced by the people in power, in fact its infective power seems to defy territorial confinement.

Lastly, for the sake of correctness of information, the Bose Institute of Calcutta is not and never was engaged in training graduates, nor is there any emphasis on nuclear physics in its research programmes. Neither of the two Boses received Nobel prizes, on which point there seems to be some misunderstanding (p.589-90).



R. MAJUMDAR
Department of Ceramics, University of Leeds, Leeds LS2 9JT, UK

SIR — Your special issue on India provides a comprehensive account of accomplishments, failures and problems of science in India. The introductory note to the survey, however, contains the erroneous figure of 2.5 per cent as the annual rate of India's current population growth. The registration of births and deaths in India is far from complete, but the annual population growth rate of 2.2 per cent during 1971–81, derived from the census counts of 1971 and 1981, is considered by demographers as reasonably accurate. In a recent statement, Prime Minister Indira Gandhi gave the current annual growth rate as 1.9 per cent. The figure of 2.5 per cent instead of 1.9 per cent in the article does not, of course, affect its content or quality, but for India it means an increase of 19 million people every year instead of 14 million. Rapid population growth is a serious problem that Indian scientists and policymakers must tackle.

THE NICOLET 2090 DIGITAL OSCILLOSCOPE

TAKE A CLOSER LOOK AT WHAT YOU'VE BEEN MISSING.

DIGITAL PRECISION AND RESOLUTION LIKE YOU'VE NEVER SEEN.

Picture this. The smallest detail in *12-bit resolution,* expansion to X64, with voltage and time coordinates alphanumerically displayed. Plus the ability to record 4K data points at *speeds up to 50MHz,* with the 205A plug-in. It's what you'd expect from the digital oscilloscope that's still setting the standards—Nicolet's 2090.

DON'T MISS ANY TRANSIENTS.

The 2090 offers push button transient capture, at speeds selectable from 20 nanoseconds to 200 seconds per point, so you can record fast or slowly changing signals with ease. And *pre- and post-trigger capture* lets you see what led up to an event as well as what followed. Built-in floppy disk allows unattended operation . . . just set and forget.

THE VERSATILITY YOU'VE BEEN LOOKING FOR.

Optional RS232 and IEEE-488 bidirectional interfaces give you the ability to coordinate and manipulate data by remote computer. That means

the 2090 scope can be the front end of an entire analysis system. Not only that, the 2090's modular design allows you a choice of *four different plug-ins.* Pick the digitizer that's designed for your present application, and add other plug-ins to fit your expanding needs in the future.

SEE FOR YOURSELF.

Let us show you how easy the 2090 is to use. It's time *you* started benefiting from the tremendous digital advantage. Call us: **(608) 273-5008.** Or write: Nicolet Oscilloscope Division, 5225 Verona Road, Madison, WI 53711.

Sequence Pattern Recognition Program Instrumental in the Discovery of a Unique Sequence Pattern in the Procaryotic Genome

SUMMARY:

QUEST, a sequence pattern recognition program developed by IntelliGenetics, allowed scientists at the Institute Pasteur to rapidly search all available nucleic acid databases for characteristic nucleic acid sequences initially observed in *E. Coli.* The scientists were able to discover the location of 67 members of a family of dispersed repetitive palindromic DNA sequences unique to the procaryotic genome.

3117 3127 3137 3145
TATCAGGCCT ACAACGGCTG TCAAATGTAG GCCGGATA

These palindromic sequences could form stem and loop structures in RNA or be important recognition sites in DNA. The stem is composed of eight remarkably conserved base pairs separated by an intervening region that varies widely in length and sequence.

METHODS:

QUEST's sophisticated query formatting capabilities required only 38 sequence keys to represent over 2.3×10^{17} possible ambiguous sequences. These simplified keys were essential to the rapid search of the entire NIH GenBANK™ and EMBL DNA sequence databases. For example, the pattern for the palindromic repeat "TATC[AC]GGC N{0, 25} GCC[GT]GATA" represents over 6×10^{15} possible different sequences. Additional levels of complexity and ambiguity may be easily represented in the QUEST searching patterns.

QUEST is based on a rapid pattern searching algorithm. Any pattern of either nucleic acid or amino acid sequence can be simply expressed regardless of the naturally occurring degree of ambiguity.

Circle No.12 on Reader Service Card.

RESULTS:

Using the 38 QUEST keys, it was discovered that a characteristic 8 base pair inverted repeat (IR) sequence was found predominantly in procaryotic genomes. These palindromic IR's are present at least several hundred times in the genomes of *E. Coli* and other bacteria. These IR's are found primarily between genes and occur either singly or in clusters.*

CONCLUSION:

These inverted repeat regions, characteristic of procaryotes, support the cassette model of genomic evolution, and furthermore suggest a specific role for these sequences in genetic regulation in procaryotes.

QUEST is only one of a complete set of integrated computer resources developed by IntelliGenetics. Other programs which can help you in your research are:

CLONER Simulation and design of recombinant DNA experiments

MAP Determination of restriction maps from enzymatic digests

GENED Simplified entry of nucleic acid and amino acid sequence data

GEL Management of large scale DNA sequencing projects

SEQ/PEP Nucleic acid and amino acid sequence analyses and comparisons

IFIND High-speed nucleic or amino acid sequence homology searches

NIH, EMBL, NBRF On-line, up-to-date, annotated library of nucleic acid and amino sequences

IntelliGenetics is currently supporting over 500 molecular biologists worldwide with a complete set of programs, all fully compatible with the NIH GenBank™, EMBL nucleic acid databases and the NBRF protein sequence database. On-line support, training, consulting and documentation is provided for all products. IntelliGenetics' computer tools are available through a timesharing system, on the 32-bit supermicro BION graphic display workstation, or by software license for multi-user computer systems.

IntelliGenetics' QUEST and IFIND pattern recognition programs can now help you obtain results and reach new conclusions more rapidly than ever before.

To find out more about these powerful computer resources, call IntelliGenetics at (415) 328-4870, or send the coupon to: IntelliGenetics, 124 University Avenue, Palo Alto, California, 94301.

Genetics and hereditable IQ

A new study of IQ among adopted siblings points to hereditable intelligence, but inconclusively. Geneticists (and others) should not however be fearful of a determination of the question.

Is human intelligence genetically determined, environmentally conditioned or the product of both influences? Since the work of the late Cyril Burt was discredited some years ago, the ferocity seems to have gone out of the argument on this question that had been raging for close on half a century. The article that appears on p.620 of this issue, yet another piece of evidence that is by itself inconclusive, will in no sense reawaken that argument. It may however be an appropriate occasion for asking what would happen if ever the question were finally decided.

What T.W. Teasdale and David R. Owen have done is to attempt to discover in measurements made with genetic siblings brought up separately, usually as a consequence of adoption, the degree to which intelligence (as represented by measured IQ) is genetically determined. The study has been made possible by the accessibility of the adoption register in Denmark, and by the ready availability of data on educational attainment, IQ and height (as well as other physical attributes) for males who must register for military service at the age of eighteen. The availability of these data is in part a justification of the pleas that social scientists have been making in recent years that legislation to protect the privacy of individuals should not disallow access for the purposes of legitimate research.

The numbers involved in the study now reported are comparatively small. Five groups of sibling pairs (all male, since women do not register for military service) have been identified, of which two groups have been used, for practical purposes, as controls. One of these groups comprises genetically unrelated males adopted by the same parents and brought up together, the other a larger group of genetic brothers brought up by their natural parents. One essential element in the design of the study is the use of measurements of height (at the age of eighteen) as a kind of control variable. There is a wealth of earlier evidence to suggest that height is indeed heritable, so that height and IQ should behave similarly if, indeed, IQ is inherited.

The outcome of the study, so far as it goes, favours the hypothesis that intelligence is indeed genetically inherited. This, at least, is the outcome of a correlation between the IQs of adopted siblings reared apart. The standard calculation that this result may have arisen by chance yields a satisfactorily low value — the odds are one in 200. But as with other studies of this kind, only some of the crucial questions that will arise in discussion of these data have at this stage been taken up. How comparable were the families into which the several groups of children were adopted? May there not be systematic differences between the families adopting related and unrelated siblings (other than the observation by Teasdale and Owen that parents adopting more than one child are likely to be well off)? One odd feature of the data now reported, however, is that the expected correlation in height among separately reared siblings does not unambiguously show up. The explanation may be the small size of the groups of adopted children, but until other explanations are excluded, the precise significance of this study cannot be certain.

None of this implies that the study has no immediate bearing on the question of whether intelligence is heritable. On the contrary, and at the very least, the study is an imaginative pointer to a source of data on heritability that has previously been almost entirely overlooked. One especially valuable feature of the Danish data is that the records of adoption and the measurements of IQ have been carried out for quite different purposes than that of the authors. Even if Burt's studies of genetic inheritance in identical twins had not been discredited by the suspicion that they may have been crudely fabricated, the fact that he was personally responsible for the measurement of IQ would by now have put his claims in doubt. One of the immediate consequences of what Teasdale and Owen have done will be to stimulate a search for other objectively gathered blocks of data that may throw light on the heritability of intelligence.

But why bother? One common assertion is that when a positive result (in favour of heritability) would be socially divisive, no good purpose can be served by answering the question. Such a response cannot however be regarded as a serious impediment to serious enquiry. If indeed IQ were shown unambiguously to be genetically determined, the result would be interesting in its own right and stimulating of other investigations. And even if it were the case that IQ is only a crude representation of what should properly be understood by intelligence, it would be even more remarkable that such an artefact, constructed from the ease with which individuals carry out artificial tasks, should be genetically determined than that unmeasured and perhaps unmeasurable intelligence should thus be determined.

Precisely what the practical consequences would be of a conclusive determination of the hereditability of IQ is another question. In the ancient row between the nature and nurture schools, it has commonly been assumed that the truth must be uncomfortable for one side or the other. That view should carry very little weight. For nobody pretends that if IQ is inherited, the effects can be as simple as in, for example, the inheritance of well-known physical disorders where a single gene may be responsible.

Everybody agrees that IQ, if inheritable at all, is determined by several genes, perhaps even indirectly. The result is that the IQ of the offspring of parents of known intelligence will be determined by some distribution spanning a range of measured values. Offspring of high-IQ parents will frequently have low IQs. Exactly the same kind of overlap is found in the distribution of IQ in racially different groups of children attending the same schools.

The consequence of these expectations of how measured IQ is likely to be distributed is that even when the question of heritability has been settled, few useful guides to social policy will have been provided. It will remain the case, for example, that societies that insist on educating the offspring of successful parents separately from others, on the twin assumptions that success denotes intelligence and that all offspring of intelligent parents are themselves intelligent, will imperfectly satisfy the needs of many of the children. It would be similarly profligate of human potential to suppose that, if IQ is heritable, schooling as such might be abolished on the grounds that native wit will make itself apparent.

In the whole field of social policy, exactly similar considerations apply. A determination of the question whether IQ is heritable would be largely irrelevant to policy, which is not to say that it would never be used as a means of justifying irrational prejudices. This is why studies such as those of Teasdale and Owen are warmly to be welcomed, why there is the strongest case for hoping that the issue will soon be clarified — and then for learning something of the mechanism by which such a fuzzy attribute of the central nervous system as intelligence may be, even in part, heritable.

Cancer chemotherapy

DNA amplification and multidrug resistance

from Piet Borst

SINCE 1978, when Robert Schimke and his co-workers showed that it could be associated with the development of drug resistance in eukaryotic cells[1], gene amplification has been shown to underlie resistance to several drugs and toxic compounds in a variety of eukaryotic cells, including such unicellular organisms as fungi and protozoa (see ref. 2 for an excellent recent review). There have also been hints that it underlies another form of drug resistance in mammalian cells — the intriguing multidrug resistance (or pleiotropic drug resistance) in which the induction of resistance to one drug leads to cross-resistance to a motley assembly of other drugs with widely different chemical structures and cellular targets[2-6]. Direct evidence that multidrug resistance is due to gene amplification has been missing. That lacuna is filled by the paper of Roninson *et al.* on page 626 of this issue[7].

Schimke's studies were on the development of resistance to methotrexate (MTX), an inhibitor of the enzyme dihydrofolate reductase (DHFR). Resistance to it can arise in at least three ways[3,4]: by a decrease in the carrier-mediated uptake of MTX; by the production of an altered DHFR; and by the increased production of normal DHFR. Schimke and co-workers showed that the third route involves an amplification of the structural gene for DHFR[1].

How does the genome know that DHFR has been blocked by MTX? The answer seems to be simple: MTX inhibits cellular DNA synthesis; when the block is released by removal of the drug, chromosome segments that have partially replicated will not only continue the old replication round but also re-replicate, producing an extra copy of that region. Once gene amplification is underway, selection with MTX ensures that cells with the largest number of copies of the *DHFR* gene will have the best chance of surviving. By stepwise increase of the drug concentration, one can eventually obtain cells with many copies of the gene. (For more on the relationship between amplification and replication the reader is referred to David Denhardt's article in these columns last week[8].)

The extra gene copies produced by amplification may either be re-inserted back into chromosomes to yield homogeneously staining regions (HSRs) or remain as extra 'minute' chromosomes, often found in pairs as double minutes. HSRs are stable when cells are grown without drug, but maintenance of double minutes usually requires continuing drug selection because they lack a centromere. Random distribution of double minutes among daughter cells and loss to the cytoplasm rapidly leads to the emergence of cells that have lost most or all of their double minutes; this instability is a hallmark of drug resistance due to this type of gene amplification (see refs 2, 9–11).

The presence of double minutes in multidrug-resistant cells, as well as the unstable nature of multidrug resistance, has strongly indicated that this, too, is due to gene amplification[12,13]. Resistance of this type can be induced with colchicine, a drug that prevents tubulin polymerization, or with one of the carcinostatic anthracyclines, drugs with diverse effects on cells. Cross-resistance develops to a group of drugs whose only features in common are a molecular weight between 350 and 1,250 and an amphiphilic aromatic nature. This indicates that multidrug resistance is due to altered drug transport, but whether the mutation results in decreased drug entry, increased efflux or a combination of these mechanisms is still not certain[2-5].

A corollary of this type of drug resistance is the overproduction of a large membrane glycoprotein with a molecular weight around 170,000. A reasonable hypothesis is that this membrane glycoprotein is encoded in the amplified DNA[13]. This cannot be the whole story, however, because different multidrug-resistant cell lines show different degrees of cross-resistance to individual drugs.

The direct evidence for gene amplification in multidrug resistance provided by Roninson *et al.* in this issue of *Nature* comes from the use of an elegant, in-gel, renaturation technique. The authors show that two multidrug-resistant Chinese hamster cell lines contain amplified DNA segments, absent in revertants. They have cloned one of the amplified segments as recombinant DNA in *Escherichia coli* and show that the degree of drug resistance correlates with the number of copies of this segment in the DNA of resistant cells. The two cell lines have different patterns of cross-resistance, and it is therefore of interest that the two lines have only part of the amplified DNA segments in common. This suggests that at least three proteins can contribute to multidrug resistance: one preferentially induced by anthracylines, one by colchicine and one induced both by anthracyclines and by colchicine. It should not be too long before the gene products of these amplified genes have been identified.

What is the relevance of this sophisticated molecular biology to the clinician treating cancer patients? Only limited information is available to answer this question. Amplification of the gene for DHFR has been shown to occur in tumour cells from patients who have had prolonged treatment with MTX[14-18]. Multidrug resistance is frequently observed in patients, but whether gene amplification contributes to it is not known. Once the amplified genes in multidrug-resistant human cell lines have been cloned it should be easier to test for amplification of these genes in tumour biopsies by standard molecular and cytological hybridization techniques. I expect that these experiments will give positive results in a significant fraction of patients exposed to intensive treatment with carcinostatic drugs. Most carcinostatic drugs block DNA replication; some of these drugs act on DNA in a similar fashion to certain carcinogens which are among the most effective inducers of gene amplification[1, 19-21]; and the schedules of drug administration used by clinicians are not incompatible with induction of gene amplification.

If gene amplification is important for clinical multidrug resistance, a more complete understanding of the phenomenon might be useful. Knowledge of which gene is amplified could allow prediction of cross-resistance to other drugs. Knowledge of the detailed mechanism of drug exclusion could lead to the design of modified drugs not affected by the exclusion mechanism. The membrane proteins overproduced could form useful targets for antibody-coupled toxins. Multidrug resistance is obviously an area where gene amplification will induce research amplification. □

Mathematics

Soap bubbles and catastrophes

from Ian Stewart

MANY mathematicians think in pictures, and maintain that geometric ideas offer some of the most important insights in the subject. Others, who think in symbols, disagree. Be that as it may, a number of topics in the mainstream of current mathematical research have clear links to geometry. A recent example[1] combines ideas from the theory of minimal surfaces with Thom's theory of catastrophes[2-4] to shed new light on an old problem posed by soap bubbles.

The study of minimal surfaces goes back to the (blind) Belgian experimentalist Joseph Plateau, who in 1873 published a book, *Statique Experimentale et Théorique des Liquides soumis aux seules Formes Moleculaires*, dealing with the shapes assumed by soap films under various constraints. In particular he noticed that if a closed loop of wire is dipped in a solution of soap and glycerine, a surface forms, spanning the wire. Many elegant shapes can be constructed in this way. If gravity is ignored, such a surface will minimize the energy due to surface tension, that is, its area. Hence the name 'minimal surface'. The 'plateau problem'[5] asks for a rigorous formulation of this concept, and a proof that an arbitrary loop can be spanned by a minimal surface. It has been solved, in various settings (for example, refs 6–8); it has also been considerably generalized.

Catastrophe theory, on the other hand, deals with discontinuous changes in the state of a system having an underlying continuous structure. In its simplest and best known version, elementary catastrophe theory, it studies systems that minimize some energy-like potential function. The best known example, the cusp catastrophe, provides a universal description of the local competition between two stable states. Despite criticism of some speculative models, catastrophe theory has proved applicable to a variety of problems[9,10], though not always those originally envisaged by its creators. Now another area of application has emerged to augment the ever-growing list, and to confound further the pessimists.

About a decade ago, Poston observed that soap films appear to undergo catastrophe-like changes when the loop that they span is slowly deformed[11]. Specifically, if a loop is constructed in roughly the shape of the seam on a tennis-ball, the film will span two stable minimal surfaces (by symmetry); but if it is opened out into a flat circle, it spans a unique surface. Poston argued persuasively that the transitions between these competing states should be described by cusp catastrophe geometry, but gave no proofs. This conjecture has now been demonstrated rigorously by Beeson and Tromba[1].

They find it convenient to work with a specific shape of loop, yielding a surface known classically as 'Enneper's surface'. The variational nature of the problem (minimizing area) is highly reminiscent of catastrophe theory (minimizing potential), but there are technical difficulties. In particular, catastrophe theory is usually formulated for a finite-dimensional set of states, whereas minimal surface problems require an infinite-dimensional set. Nevertheless, Tromba has developed techniques[12,13] to render catastrophe theory applicable to the minimal surface problem, although a number of obstacles must still be overcome. The results add to the available knowledge on a difficult and important problem: how many minimal surfaces are there that span a given loop? Indeed, they furnish the first explicit example of a non-unique solution. The results also contribute to the generalization of catastrophe theory to variational problems in infinite dimensions, thereby bringing several new areas of application within its scope. □

Botany

St Helena Ebony tree saved

from Mark Williamson

ST HELENA is probably best known as the oceanic island to which Napoleon was exiled. To biologists it is also known for its extinct flightless birds and remarkable endemic trees. It is also a classic example of the destruction of the biota of an oceanic island by man[1]; the introduction of goats and other species and the stripping of bark for tanning have all contributed to the decline of the native flora. Therefore, particularly as 1984 is Plant Year of the World Wildlife Fund, it is a pleasure to record that about 12 species endemic to St Helena are now being cultivated[2], including one that had been thought to be extinct for 130 years.

The island is a mere 121 km^2, lying in the South Atlantic at 16° south. It is ringed by cliffs rising to 200 m or more, while the centre of the island rises to just over 800 m. It was formed by volcanic action 7–15 Myr ago, in the Miocene. A mere 36 species of flowering plants are definitely native[3,4] and no fewer than 33 of these are endemic. Another 20 or so species may be native, but even with them the list would be remarkably short. An equivalent area in England would have roughly ten times as many species.

Two of the most remarkable of the endemic species are the Redwood[5] and the Ebony, now placed in a genus of their own, *Trachaetiopsis*[6], in the Sterculiaceae, a chiefly tropical family which includes the Cocoa and Kola trees. The nearest relatives of the Ebony and Redwood are the six species of *Trochetia* found only on the islands of Mauritius and Réunion in the Indian Ocean. The Ebony seems to have been a dominant small tree in the lower arid parts of the island, while the Redwood was found in the more mesic zone higher up[7].

Whereas the Redwood has continued to survive on St Helena, albeit now only in gardens, the general assumption had been that the Ebony became extinct sometime after the 1850s. But in November 1980, George Benjamin, a forest guard, and Quentin Cronk, of the University of Cambridge, found two bushes of Ebony growing on a cliff[8]. In January and February 1983 Cronk was back on the island with Simon Goodenough, of the Royal Botanic Gardens, Kew. Cuttings from the Ebony were established[2,9] and the plants have now flowered at Kew. The Ebony can be propagated both by cuttings and by seeds, and there are now plans to plant several hundred back on the island[2]. Since all the plants are derived from two bushy individuals, the genetic type and range of the survivors may differ appreciably from the generality of the original stock. But it looks as though the species has been saved. □

Rheumatoid arthritis

Another viral candidate

from K.A. Brown

DEVOTEES of the school that believes an occult virus is responsible for the induction of rheumatoid arthritis will have welcomed a recent article summarizing a three-year collaborative study undertaken in three USA centres on the identification of parvovirus-like particles in synovial tissue from the joints of rheumatoid arthritis patients[1]. For the sceptics in this field, the publication heralds the arrival of yet another viral candidate whose association with rheumatoid arthritis, if any, will be shown to be circumstantial and which warrants investigation simply because it is one of the few viruses which has not already been the subject of an attempt to associate it with the disease.

The research of Simpson *et al.* stems from their isolation of an infectious agent, termed RA-1, from rheumatoid synovial cells, co-cultured with human lung fibroblasts or rabbit fetal synovial cells, and subsequently passaged in suckling mice. Injection of RA-1 into the cerebral area of the brain of neonatal Swiss–Webster mice produced a fatal neurological disease, whilst its inoculation into the peritoneum produced several symptoms, notably permanent crippling, alopecia, conjunctivitis and dwarfism. Such fatalities and disabling effects were not induced by synovial extracts prepared from patients with the non-inflammatory disorder osteoarthrosis.

In their size (24–25 mm), morphology and resistance to chemical and physical treatment, the infectious particles resemble a parvovirus. Parvoviruses are among the smallest of the DNA viruses. There are two main genera: the adeno-associated, whose replication is 'defective' and requires the help of a co-infected adenovirus; and the adeno-independent, whose replication does not require assistance. In domestic animals parvoviruses are believed to be responsible for such conditions as panleukopenia and enteritis in cats and hepatitis in dogs and geese. Human 'serum parvovirus-like virus' was discovered during the screening of symptom-free blood donors for hepatitis B virus antigen[2]. This adeno-independent virus, often referred to as the B19 virus, was shown to induce febrile illnesses in haematologically normal people[3], aplastic crisis in patients with haemolytic anaemia due to infection of a haematopoetic progenitor cell[4] and to be transmitted to haemophiliacs in blood clotting factor concentrates[5].

Since established laboratory cell lines may be contaminated with parvovirus, there is always a risk of parvovirus contamination during the co-culture and passage stages of experiments. However, Simpson *et al.* show that injection of rheumatoid arthritis synovial cells into murine brains, without prior co-cultivation with accessory cells, induces the appearance of the RA-1 virus. Furthermore, the RA-1 antigen does not react with antisera directed against several other parvoviruses which infect mice and other animals.

On caesium chloride equilibrium gradients, the RA-1 viral particles are found at a density of 1.30 – 1.43 g cm^{-1}. In a collaborative study which is shortly to be submitted for publication, Gabi Stierle, a visiting scientist to our department, demonstrates that caesium chloride fractions of 1.41 g cm^{-1}, prepared from synovial cells of five of eleven rheumatoid arthritis patients, but none of six osteoarthritis patients, react with an antibody against RA-1. The immunoreactive rheumatoid fractions contain abundant particles of 10 nm diameter whilst 23 nm particles are seen in similar isolates from long-term rheumatoid synovial cultures. The rheumatoid fractions do not react with the monoclonal antibodies to the B19 virus. This finding, together with the failure of the B19 virus to react with the anti-RA-1 antibody and the high prevalence of the anti-B19 antibody in 61 per cent of the population[6], suggests that it is unlikely that the B19 virus has an important role in rheumatoid arthritis[1].

Parvovirus is the infectious agent of Aleutian disease in mink, a slowly progressive fatal disorder characterized by hypergammaglobulinaemia, anaemia, immune complex-mediated arteritis and glomerulonephritis[7] and thought by some investigators to have features of autoimmune disease. There is no evidence to suggest that parvovirus may directly initiate a synovitis, though the affinity of the virus for host cells that are of high mitotic activity, particularly activated lymphocytes[8] and endothelial cells[9], and its dissemination by monocytes and macrophages[8] are attributes which might be expected of a polyarthritogenic agent. It is premature to indulge in conjecturing possible implications of the work of Simpson and Stierle for rheumatoid arthritis. We must await definitive characterization of the RA-1 virus by techniques such as cell hybridization, serological evidence of parvovirus infection, laboratory studies performed on patients with inflammatory arthritides other than rheumatoid arthritis, and cytopathogenetic studies using adenovirus and other viruses which might support its replication.

Simpson *et al.* are to be encouraged in their persistent and patient search for a replicating virus in rheumatoid arthritis, a task that seems fraught with almost insurmountable biological and technical obstacles. Whatever the outcome, they will have resurrected interest in an area which urgently requires more motivated scientists of enthusiastic application and original approach. Progress is painfully overdue. □

PILE-DWELLINGS ON HILLTOPS

AMONG the Miris, Singphus, Kamtis, Nogas, Mismis, and Deodhains that I have questioned as to the origin of the custom of building on piles, the answer is invariably that they do not know, that it is their tribal custom, &c. Pressed as to the advantages of it, or why they could not build on the ground like Hindus, they generally end by urging the absolute necessity of keeping things out of reach of the ever-present pig.

As an illustration of how this animal practically affects the question of house-building, I append a section of a typical average Noga house, as built by the tribes south-east of Sibsagar to the Upper Dihing. One end generally rests on the ground, while the other overhangs a slope for which there often seems to be no occasion, as plenty of level land is about. In all houses of this type the end devoted to husking rice rests on the ground, and the door at the end has a slab that can be raised to admit pigs to eat the husks. This compartment (one-third of the house) is divided from the living and sleeping part by a wall and a door with a stile to keep out pigs. There are generally from two to six, or more, sleeping-rooms on the ground, and beyond them again is an open room used for visitors, or to sit and work in during wet weather.

From *Nature* **30**, 168, 19 June 1884.

But there are many other things besides pile-dwellings that prove these now distinct tribes to have descended from a common stock. The "morongs," or houses in which the lads and single men sleep at night, away from their parents' houses, are seen under various names all through these hills. There are also "morongs" for the girls and single young women, and there are special and peculiar laws relating to morongs. Liberty of the sexes before marriage is indeed practically so complete among all these tribes that really *morals begin with marriage*. After marriage they are better, I think, than civilised nations.

Catalysis

Zeolites under control

from Lovat V.C. Rees

ON page 589 of this issue of *Nature*, Haag *et al.* report a very nice example of the way in which zeolites can be used in the controlled catalysis of hydrocarbon cracking, which is best seen in the context of John Dwyer's brief but comprehensive overview of zeolites as acid catalysts in the 2 April issue of *Chemistry and Industry*..

Zeolites are crystals of alumino-silicates permeated by channels and cages of molecular dimensions. The active catalytic centres are hydroxyl groups — one for each Al atom — which are readily generated by deammoniation of ammonium-exchanged zeolites on heating to 400°C. On heating to temperatures greater than 550°C, however, these Bronsted acid sites are converted to Lewis sites by loss of H_2O. John Dwyer clearly indicates the importance of zeolites in elucidating the fundamental mechanisms involved in the catalytic conversion of hydrocarbons. Since zeolites can readily be synthesized over a very wide range of Si/Al ratios, it is possible to create catalysts with active centres whose average separation distance can be varied in a controlled way. Also, by choosing specific zeolite structures from a large list, channel and cage geometry can be varied. Specific channel geometries can also be modified by various techniques.

With this ability to finely tune zeolite catalysts, it is possible to observe the effect of increasing the acid strength on, for example, the product ratios resulting from the isomerization of butenes. The shape-selective behaviour of zeolite catalysts can be readily quantified. Thus reactant and product shape-selectivity and restricted transition-state-selectivity can be explained. The size and shape of the channels and cages exert both geometric and diffusional restrictions. The size of the crystals, coking, steam treatment and chemical modifications affect the products of a reaction in easily explained ways.

It is usually quite difficult to identify and count the number of active sites involved in a catalytic reaction but that is not the case for ZSM-5, the zeolite studied by Haag *et al.* and in which it is possible to have such a high ratio of SiO_2 to Al_2O_3 that the Al atoms are no longer a structure-determining constituent. Haag *et al.* varied the Al content of ZSM-5 from 20 to 10,000 p.p.m. such that the average distance between Al sites represented several to a very large number of atomic diameters and the distribution of the sites will have approached one of randomness. There is, thus, a substantial chemical uniformity to the catalytic sites.

The activity of these samples towards the cracking of *n*-hexane in controlled conditions was linearly related to the Al content and extrapolated to zero activity at zero Al content. This quantitative correlation can be explained only if all Al atoms are in tetrahedral framework locations — which is exactly how they are shown to be arranged by high-resolution magic-angle spinning nuclear magnetic resonance.

With such accurate quantitative data it is possible to determine the number of active sites, the absolute molecular turnover rates and the turnover numbers. Haag *et al.* found an absolute turnover rate for *n*-hexane cracking of 2.8 molecules per minute per atom of Al over the entire Al concentration range. Since the reaction rate is first order, the fraction of occupied Al sites at 100 torr is less than 1 per cent of the total Al sites and the turnover rate per occupied active site (the turnover number) is greater than 300 molecules per minute per active Al site.

The reaction rates for other reactions, for example 1-hexane cracking and 1-hexane double-bond isomerization, have also been shown to be linearly dependent on the Al concentration. The olefin cracking rate is some 800 times the paraffin cracking rate while the olefin isomerization rate is some 1,300 times the olefin cracking rate. The Al concentration needed to achieve technically relevant reaction rates can be less than 1,000 p.p.m. for paraffin conversion and from a fraction of a p.p.m. to 100 p.p.m. for other conversions. Turnover numbers as large as 4×10^7 can be obtained with zeolite catalysts; not dissimilar to the values in enzyme catalysis.

Ultra-stable zeolite Y is currently used as the cracking catalyst in oil refining. It cannot be synthesized with a ratio of SiO_2 to Al_2O_3 greater than 3, but this ratio can be increased by various de-alumination processes. These impart additional thermal stability but lower the crystallinity, and the resulting catalyst is still too active and requires dilution with catalytically inactive binder material. Even then, coking of the catalyst pellets occurs in a reactor in a time scale measured in seconds. The data of Haag *et al.* on ZSM-5 indicate how little Al is necessary for cracking reactions and should spur zeolite chemists on to discover a method to produce zeolite Y with very much less Al than used at present. Very interesting technical problems will have to be overcome to produce such a catalyst.

Finally, Martens *et al.* show that a relatively simple test can be used to obtain a detailed insight into the structure of the channels and cages of zeolites (*Zeolites* **4**, 98; 1984). Using *n*-decane isomerization and hydrocracking reactions over platinum-loaded hydrogen zeolites as a fingerprint, five independent criteria can be found which give consistent and supplementary evidence on the structure and dimensions of the void space in zeolites. Voids that are characterized in terms of unidimensional pores made of 10-membered rings of oxygen atoms are readily distinguished from those that are cages of varied dimensions accessible through pores made of 8- or 12-membered rings. Surely the consistent reproducibility of these catalytic reactions indicates the uniqueness of zeolites as catalysts. □

Immunology

T-cell development in the thymus

from Ken Shortman

MUCH of the development of T lymphocytes takes place in the thymus, away from the melee in bone marrow where B lymphocytes and other haematopoietic cells differentiate side by side. What is the purpose of this convenient packaging? Is the thymus an inductive environment for switching the differentiation of uncommitted stem cells into one of the T-cell lineages? Or is it an immunological finishing school, generating a diversity in the antigen receptors on the surface of T cells and selecting those most suitable for recognizing foreign antigens presented in the context of 'self' (major histocompatibility) antigens on the surface of cells. Or is it both? A careful study of what goes in and what comes out can set the limits of what might happen in the thymus itself.

Recently devised techniques[1,2] for labelling cells within the adult mouse thymus and for tracing labelled emigrants into the periphery have shown that emigrant cells are much like mature T cells, are already committed to one or other of the specialized T sublineages and are already functional. The essential development of the cells must have occurred within the thymus, or even before their arrival there. The output from the thymus is low, however: only about 3 per cent of the cells produced daily leave the thymus, the rest apparently dying within it. Although this high attrition rate suggests a stringent culling for appropriate specificity, it could equally well reflect a low efficiency in the formation of a functional T cell of any specificity.

The other part of the equation, the seeding of T cells in the thymus, is considered by Ezine, Weissman and Rouse on page 629 of this issue of *Nature*[3]. They have studied the reconstitution of the T-cell

population of the thymus of mice whose haematopoietic stem cells, including those for T cells, have been destroyed by irradiation. For the purposes of reconstitution, Ezine *et al.* supplied the mice with a mixture of a large number of bone-marrow cells from identical mice and a small number from congenic mice that carried a different T-cell surface marker. It was thereby possible in immunohistological studies of frozen thymic sections, prepared several weeks after reconstitution began, to tell which T cells had originated from which stem cells. The results were similar to those that had been previously obtained using a chromosome marker[4]: often thymus lobes contained no cells of congenic type and in other cases discrete foci of congenic-type cells were seen, and occasionally an entire thymus lobe was uniformly of that type. This pattern of distribution indicates that the thymus is recolonized by very few 'stem' cells, and sometimes by only one. As Ezine *et al.* point out, although this model does not tell us the actual number of stem cells colonizing a thymus throughout embryonic development, it does suggest it could be small compared with the size of the T-cell specificity repetoire. That argues in favour of the generation of receptor diversity within the thymus.

The second issue raised by the study is the long-disputed relationship between the thymic cortex and medulla. The medullary region of the thymus contains most of the organ's phenotypically and functionally mature cells (about 10 per cent of the total cell population). The simplest interpretation is that these are the immediate source of cells destined for export, although there could be a similar, but small and transient, pool of such cells in the cortex. The cortex contains the majority of dividing cells and the majority of thymocytes, most of which are both non-functional and phenotypically different from mature T cells. The simplest interpretation would be that these are the immature precursors of the medullary population, but this does not accord with the intrathymic death of most cortical cells. The medullary and cortical populations in fact display a large degree of independence in cell kinetic studies[5,6].

Nevertheless, Ezine *et al.* report cases where both cortex and medulla appear to be repopulated by a single clone, suggesting that a single stem cell has initiated a cell lineage which populates first the cortex and then the medulla. A subpopulation of apparently cortical blast cells, capable of reconstituting both cortical and medullary compartments, was reported by B.-J. Fawlkes and B. Mathieson at the meeting on T-cell differentation at the Basel Institute for Immunology last November. This could be a later intrathymic stage of the type of bone-marrow stem cell suggested by Ezine *et al.* Note, however, that Ezine *et al.* also report instances where only the medulla showed reconstitution with congenic-type cells, suggesting a direct seeding of the medulla without cortical involvement. The studies of Joterau and Le Douarin[7] on colonization of the avian embryonic thymus also suggest independent seeding of the cortex and the medulla.

Why there might be two separate developmental pathways, one cortical to medullary, one medullary alone, is far from clear. It would make more sense if T-cell sublineages of different function were handled in different parts of the thymus. With our present knowledge, it would be more sensible and comprehensible if all T-cell development, from stem-cell immigrants to functional T-cell emigrants, took place in the medulla. It is the involvement of the cortex, with its high level of both cell generation and cell death, and with its non-functional lymphoid cells of peculiar surface composition, that forces us to acknowledge there is something interesting happening in the thymus that we still do not understand. □

Earth science

Anomalous satellite motion and mantle viscosity

from Kurt Lambeck

FOR many years geodesists have examined evidence for the temporal changes in the Earth's global shape and gravity field. Confirmation that such changes occur on time scales of at least several years has now emerged from the observation of a secular acceleration $\ddot{\Omega}$ of the node Ω of the orbit of the satellite Lageos[1,2], launched by NASA in 1976 and tracked ever since with high-precision laser-ranging equipment. Acceleration of the node implies a secular change in the flattening of the Earth and the most obvious explanation of this — the mass readjustment inside the Earth associated with the rebound of the crust after the melting of the Late Pleistocene ice sheets[1,2] — has recently been analysed in detail by Wu and Peltier[3].

One benefit of the measurement of the anomalous orbital motion is that it will provide an additional estimate of the viscosity of the mantle, a quantity that is central to discussions of mantle convection yet remains uncertain. The information on viscosity contained in the observation of $\ddot{\Omega}$ is the same as that contained in the observation of the Earth's secular acceleration but the latter is contaminated by other physical processes, most notably the secular tidal contributions; as a result no accurate figure for the non-tidal acceleration is available. Furthermore, non-tidal acceleration cannot be uniquely associated with the post-glacial rebound; for example, very long-period contributions could arise from electromagnetic coupling forces acting at the core–mantle interface. The orbital perturbation in the node may therefore reflect a more direct measure of the mantle's effective viscosity.

The power of the analysis of satellite orbits to determine the dynamic flattening, J_2, of the Earth with high precision is well known[4]. Nonetheless, observations of temporaral fluctuations in this quantity have proved elusive. What was missing, until Lageos, was a satellite that could be tracked with great precision and whose orbital motion was almost entirely governed by the Earth's gravity field.

The two studies use nearly the same Lageos data and there are many similarities in the orbital analyses used. Yet their results for the secular accelerations differ significantly: Rubincam[2] obtains $(-10.8\pm2.4)10^{-3}$ arc s yr^{-2} as the value of $\ddot{\Omega}$ while Yoder *et al.*[1] obtain $(-14.7\pm1.3)10^{-3}$ arc s yr^{-2}. Are we in for another long debate on the correct value of a secular variation, matching that of the Earth's non-tidal secular rotation? Why do these differences occur? The problem may be partly one of contamination by long-period tidal contributions because superimposed upon the secular motion of Ω are long-term periodic fluctuations due to the tidal deformations of the Earth, principally the 18.6 year tide. The periods of these tides are well known but the amplitudes are not, primarily because both the ocean response and departures of the solid Earth's response from that of an elastic body remain uncertain[5]. Thus with only 5.5 years of data the Lageos results are still very preliminary. In more leisurely times the authors would have patiently waited until a much longer record had been painstakingly acquired, but one cannot be sure that NASA will still be tracking Lageos a few years from now.

Whatever the exact answer, Wu and Peltier believe it can be explained as the response of the Earth to the new surface load following the removal of the Pleistocene ice from the glaciated continents and the addition of an equal water-mass to the oceans. Locally, sea level and gravity are changing through time; globally the Earth's rotation and the node of satellite

orbits undergo secular changes. Many attempts have been made to deduce mantle viscosities from these direct and indirect observations of the post-glacial rebound but the results have remained conflicting. What can be said is that nearly all observations are accommodated by mantle models of uniform Newtonian viscosity of 10^{21}–10^{22} P. Where controversy arises is in whether there is a significant depth-dependence of viscosity, whether this viscosity is linear and whether there is evidence for lateral variations in viscosity[6]. A principal reason for this state of affairs is that the results are only as good as our inadequate knowledge of the distribution and melting history of the ice loads themselves, partly determined by the rebound observations, particularly by observations of sea-level changes[7-9].

The new J_2 or $\ddot{\Omega}$ observations are largely consistent with the uniform and Newtonian viscosity range of 10^{21}–10^{22} P. Wu and Peltier[3] have attempted to combine this observation with those of the rotational response to deglaciation and conclude that the data imply there to be a thick elastic lithosphere overlying an upper mantle of viscosity 10^{22} P and a lower mantle viscosity of 1–3×10^{22}P. The average thickness of this elastic lithosphere is estimated to be about 120 km with the continental layer being about 200 km thick. This conclusion is reached by assuming a viscosity profile that is determined by local observations of rebound[10] and then determining the lithospheric thickness from the rotation data. The conclusion therefore remains dependent on the assumed ice history. Other recent studies[7-9] have shown that the proposed melting histories remain inadequate to explain sea-level changes in tectonically stable regions far away from the ice loads and point to mantle viscosities that are less than 10^{22} P. As long as the conclusion of a thick average lithosphere is not dependent on the assumed ice load, these observations raise the interesting possibility that there are substantial regional variations in viscosity, for the far-field Holocene sea-level fluctuations are responsive mainly to the mantle flow induced by the added melt-water rather than the flow under the former icesheets. □

Oncogene activation

Message of *myc* in context

from Miranda Robertson

THERE are two reasons for the exceptional concentration of research on the cellular *myc* proto-oncogene (c-*myc*). The first is historical. The chromosomal translocations characteristic of Burkitt's lymphomas transfer c-*myc* from its normal context into an active immunoglobulin locus[1], where it was quickly identified by a number of research teams whose vigorous investigations on the molecular basis of antibody diversity were immediately deflected to the molecular basis of cancer. The second is the nature of the c-*myc* gene itself. Unlike many other oncogenes, c-*myc* is expressed in a wide variety of both normal[2] and tumour[3] tissues, and can therefore be expected to have some general significance. This expectation is borne out by two recent papers directly implicating c-*myc* in the control of normal and abnormal cell growth[4,5].

The implication of all the recent research, broadly, is that what changes during tumorigenesis is not c-*myc* itself but the regulation of its production. The evidence comes partly from the two recent papers[4,5] on changes in c-*myc* expression during the growth cycle of tumorigenic and non-tumorigenic cells *in vitro*, and partly from the latest investigations on the interaction of c-*myc* with the regulatory mechanisms operating on the immunoglobulin locus in Burkitt's lymphoma cells.

c-*myc* and the cell cycle

The data on the cell-cycle regulation of c-*myc* come from four laboratories: those of Philip Leder and Charles Stiles[4], and those of Gail Sonnenshein and Arthur Pardee[5]. The aim of their experiments was to establish where the product of the c-*myc* gene might act in the successive steps by which cells progress through their growth cycle. There is evidence, cited in both papers, that the progression from quiescence to DNA synthesis (that is, through G_0–G_1)can be divided into roughly three phases, each triggered by different tissue-specific growth factors. The first phase is known as the phase of priming for growth competence; and it is in this phase that c-*myc* is implicated.

Kelly *et al.*[4] have been able to show that a fibroblast mitogen, platelet-derived growth factor (PDGF), and two lymphocyte mitogens, concanavalin A and lipopolysaccharide, stimulate the expression of c-*myc* in those cells that normally respond to them. All three mitogens are believed to act early in the cell cycle to induce competence; and all stimulate transient expression of c-*myc* within 1–2 hours, with a return to baseline well before the onset of DNA synthesis.

The activation of c-*myc* by PDGF is particularly noteworthy, and indeed is particularly noted by Kelly *et al.*, in the light of the very close relationship between the sequence of one chain of PDGF and that of the product of the c-*sis* oncogene[6,7]. This may be the first clear illustration of how the cellular proto-oncogenes encode different components of a single regulatory chain, disruption of any part of which could contribute to tumorigenesis.

The implication of the Campisi *et al.*[5] data is that after a normal cell has been transformed into a tumour cell, regulation of the c-*myc* gene may be disrupted in such a way that its activation is independent of growth factors. They have measured c-*myc* expression during growth and quiescence in three cell lines: the non-tumorigenic mouse fibroblast line A31, and two tumorigenic derivatives, BPA31 and DA31, both transformed by chemical carcinogens. The growth of all three lines can be arrested by starvation (though the tumorigenic cells are slower to respond); but whereas arrested A31 cells cease to express c-*myc*, the transformed cells continue to express the oncogene at the same level after arrest. Apparently, c-*myc* expression, and thus growth competence, is no longer subject to regulation by serum growth factors after transformation.

These observations are, as Campisi *et al.* point out, consistent with the existing evidence that the activation of c-*myc* depends on the disruption of the genetic control of its expression, and not with mutations affecting the function of the product. (This is by contrast, for example, with the c-*ras* family, at least some members of which can be activated by mutations in their coding sequence [8-10].) They are not, as it happens, particularly consistent with the notion, derived from the transfection experiments of Land *et al.*[11], that c-*myc* is one of a class of oncogenes whose activation immortalizes cells (A31 cells are already immortal) and that a second gene (for example one of the *ras* family) is needed to complete transformation. But then, this categorization is in any case operational and indeed Land *et al.* explicitly state that they have no direct evidence that c-*myc* transfection immortalizes. What all this probably means is that tumorigenesis is a function of interactions between different oncogenes (in the Land *et al.* experiments c-*myc* and c-Ki-*ras*) that need not be the same in all tumours. There is, for example, no way of knowing whether the deregulation of c-*myc* in BPA31 and DA31 cells is due to a change in the regulatory region of the gene itself, or to the deregulation of some other component of the pathway in which c-*myc* par-

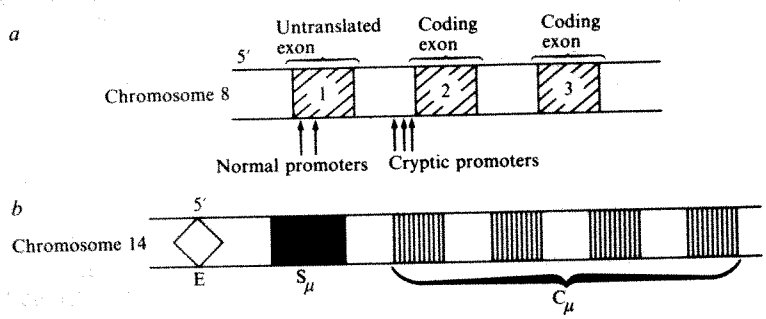

Fig. 1 *a*, The normal c-*myc* gene, which is on chromosome 8 of man, has three exons, the most 5′ of which is untranslated. It is normally transcribed from two promoters at the 5′ end of exon 1: the significance of the two different transcripts for the translational regulation of the normal gene is so far a matter of debate (see ref. 1). When exon 1 is removed from the gene by chromosomal translocation, transcription is initiated at one of a cluster of cryptic promoters within the first intron. *b*, The immunoglobulin heavy-chain locus on chromosone 14 which is involved in a reciprocal exchange with chromosome 8 in most Burkitt's cell translocations. In the normal course of B-cell differentiation, rearrangements of chromosome 14 bring one of several variable-region segments into juxtaposition with the constant-region segment, and thus under the control of the transcriptional enhancer sequence just upstream of it. *E*, enhancer; S_μ, switch sequence (this sequence participates in further chromosomal rearrangements that take place later in B-cell ontogeny but have no direct relevance to the Burkitt's translocations); C_μ, μ constant-region segment, containing four exons (shaded area).

ticipates: it might even reflect changes in c-*sis*.

It is in establishing a precise mechanism for c-*myc* deregulation that Burkitt's lymphoma cells may be important. In those cells, the c-*myc* gene on the normal chromosome 8 is silent, while its allele, which has been translocated to an immunoglobulin gene locus, is constitutively active. Thus deregulation must be associated with the translocated gene itself, or its flanking DNA. The latter could be either from the original context of c-*myc* on chromosome 8 or from its new context in the immunoglobulin locus (usually on chromosome 14).

Mutation and derepression

There have been, very broadly, two schools of thought on the mechanism of c-*myc* activation in Burkitt's cells. The first, which derives from George Klein's original observations on Burkitt's translocations[12], is that the answer lies in the constitutive activity of the immunoglobulin locus in the lymphoma cells. While everyone agrees that the immunoglobulin locus must play some part in c-*myc* activation, it has proved remarkably difficult to implicate any specific immunoglobulin regulatory mechanism: various abortive attempts have been summarized in an earlier article[1]. The alternative is that the c-*myc* gene and its own regulatory sequences are altered in the translocation. There is fresh evidence for both schools of thought.

One possibility that can almost certainly be ruled out is that c-*myc* is activated by mutations in its coding exons. The c-*myc* gene has three exons (Fig. 1*a*), of which only exons 2 and 3 are translated [13,14]. Exon 1, which is highly conserved, is suspected of subserving a regulatory function. In no case is either exon 2 or exon 3 broken in the Burkitt's cell translocations; and with one exception (which will be discussed later) no mutations have been found in the translocated coding exons (ref. 15 and C. Croce, personal communication). Attention has thus recently been focused on the putative regulatory exon, exon 1. The issue is the importance of the loss of *myc* regulatory regions relative to that of acquisition of immunoglobulin regulatory elements, in the activation of the translocated c-*myc* gene.

The evidence in favour of a regulatory function for exon 1 of c-*myc* is strong but circumstantial. Exon 1 is highly conserved across species in the cellular gene, but entirely absent from the v-*myc* oncogene of tumour viruses. This strongly implies that it is vital to the normal function of the gene but unnecessary or even inimical to its transforming function. Leder and his colleagues have put forward the theory that the 5′-untranslated region including exon 1 is the binding site for a transcriptional repressor, possibly induced by, or even identical to, the c-*myc* product itself[16]. This kind of regulatory feedback could clearly account for the transience of c-*myc* activation by growth factors; and Leder and his collaborators have bolstered their case by showing that when protein synthesis is inhibited by cycloheximide, transcription of c-*myc* in response to growth factors is prolonged[4].

The circumstantial case is further strengthened by the chromosomal translocations that are typical of mouse plasmacytomas. Like those in Burkitt's lymphomas, they almost always move c-*myc* to the immunoglobulin heavy-chain locus (see Fig. 1*b*); and in every case, the first exon of c-*myc* is either lost or truncated in the translocation. This suggests that loss or disablement of exon 1, or other sequences 5′ to the coding exons, is associated with the production of tumours. (That the truncated gene can be transcribed at all is due to a copious supply of cryptic promoters in the first intron: see Fig 1*a*.)

Burkitt's lymphomas, however, have failed to comply with this picture of c-*myc* activation: in many of them, the c-*myc* gene is translocated intact (see Fig. 2*a*). This has been interpreted as evidence that the constitutive activity of the immunoglobulin locus is more important than the state of exon 1 of c-*myc* in deregulating the translocated gene. Recent results from Leder's and Rabbitts's laboratories suggest an alternative, arising from a second specialized property of the immunoglobulin locus. Through a mechanism that is still not understood, antibody diversity is increased by the generation of somatic mutations in a discrete region of DNA normally occupied by the variable-region segment of the immunoglobulin gene. In Burkitt's lymphomas, this site is usurped by c-*myc*; and Rabbitts *et al.*[17] have shown that in one case — that of the Raji cell line — the translocated c-*myc* gene has undergone extensive mutation. Leder and his colleagues have now used sequencing and S_1 mapping to demonstrate mutations in the intact exon 1 of two more Burkitt's cell lines[18]; and Rabbitts *et al.*[19] have found mutations in yet another two.

If exon 1 of translocated c-*myc* genes were invariably either mutated or lost, this might be taken to resolve the activation issue in favour of the gene rather than the immunoglobulin locus. There are two complications, however. The first arises from Rabbitts's original data on mutations in Raji cells. These mutations extend into exon 2, the coding portion of the gene, where they result in 16 amino acid substitutions. It is hard to imagine that these would leave the myc product functionally unaffected; yet conserved myc function seemes to be essential to tumorigenesis[15].

This particular paradox is resolved by the activation, in Raji cells, of the untranslocated c-*myc* gene — which is silent in other Burkitt's lines[19,20]. Rabbitts attributes the activity of the untranslocated c-*myc* gene directly to the mutant product of the translocated one, under Leder's repressor theory. If the myc product usually mediates or induces repression of the c-*myc* gene, then a mutant product may lead to a failure of repression. This leads to another paradox, however, since the normal c-*myc* gene once activated ought presumably to induce its own repression. There are various possible ways out of this difficulty, but in the present state of knowledge they are all more or less arbitrary.

The second complication arises from some data, not yet published, from Croce and his collaborators (personal communication) who have sequenced an intact translocated c-*myc* gene from one of the so-called variant translocations (see legend to Fig. 2*d*) and have found no mutations either in the coding or in the untranslated exons. This implies that the state of exon 1 may after all be irrelevant to the deregulation of the translocated gene, although alterations to other conserved sequences 5′ to exon 1 cannot be ruled out.

Importance of context

Can any sense be made of the data so far? Yes, but only by disregarding for the time being the particulars of exon 1 and refocusing on the behaviour of the immunoglobulin locus, and the normal c-*myc* gene, in the course of normal B-cell differentiation. Both undergo sequential changes in transcriptional activity as the cell progresses from the proliferating lymphoblastoid stage to the terminally differentiated plasma cell in which transcriptional activation of the immunoglobulin locus reaches its peak. In lymphoblastoid cells, both the immunoglobulin locus and the c-*myc* gene are transcriptionally active; Burkitt's lymphomas represent a later stage of differentiation, in which the c-*myc* genes are probably normally silent and the activity of the immunoglobulin genes is increased. Mouse plasmacytoma cells, which have chromosomal translocations equivalent to those of Burkitt's cells, represent the terminally differentiated state, with immunoglobulin transcription at its height.

By making somatic cell hybrids between different combinations of these cell types, Croce and his associates have, in effect, been able to assay the regulatory signals acting on both translocated and untranslocated c-*myc* genes against each differentiated cell background. I have already discussed[1] the results of a series of experiments on the behaviour of untranslocated c-*myc* genes. The c-*myc* gene on the untranslocated chromosome 8 in Burkitt's cells is silent in the lymphoma cell but transcriptionally active in a lymphoblastoid cell background. The normal active c-*myc* genes of the lymphoblastoid cell, by contrast, are silenced when transferred to a mouse plasmacytoma cell. This presumably reflects the influence of stage-specific regulatory factors acting on the normal regulatory sequences of the c-*myc* gene.

In more recent experiments along the same lines[21], Croce and his collaborators have gone on to analyse the stage-specificity of transcriptional activation of the translocated c-*myc*, whose activity presumably reflects the normal regulatory influences on the immunoglobulin locus. Indeed, by choosing a Burkitt's cell line in which the translocation has broken both the c-*myc* gene and the immunoglobulin locus, they have been able to use the reciprocal translocations (Fig. 2*b* and *c*) to assay separately the regulatory elements of the two separated parts of the immunoglobulin locus on the separated parts of c-*myc* in two different backgrounds: lymphoblastoid and plasmacytoma.

The Burkitt's cell line that Croce and his co-workers used is ST486, in which there is a reciprocal translocation between chromosome 8, which contains the c-*myc* locus, and the immunoglobulin heavy-chain locus on chromosome 14. The break on chromosome 8 falls between exon 1 and exon 2 of c-*myc*, the two coding exons being transferred to the immunoglobulin locus on chromosome 14 (see Fig. 2*b*) while exon 1, left behind on chromosome 8 (Fig. 2*c*), is joined to a fragment of the immunoglobulin locus containing the one known tissue-specific regulatory sequence operating on the immunoglobulin genes — the enhancer sequence upstream of the constant-region segment (see ref. 1).

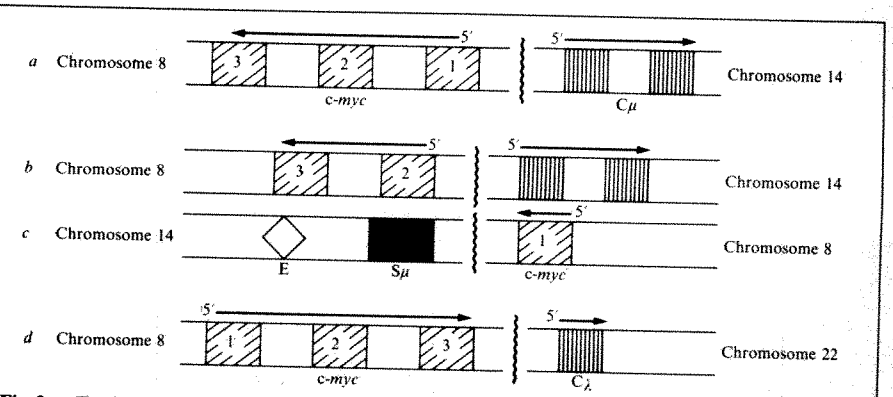

Fig. 2 *a*, Typical translocation with c-*myc* intact; *b*, typical translocation with c-*myc* separated from its exon 1; *c*, reciprocal of translocation shown in *b*. The typical translocation in Burkitt's lymphoma cells involves a reciprocal exchange between chromosome 8 and chromosome 14, resulting in the juxtaposition of the c-*myc* gene with the immunoglobulin heavy-chain constant-region locus C_μ, the two genes being in reverse transcriptional orientations (shown as 5′→). The distance of the chromosome 14 breakpoint from the constant-region locus is extremely variable; the breakpoint on chromosome 8 also varies, sometimes separating exon 1 of c-*myc* from the coding exons (*b* and *c*) and sometimes not (*a*). *d*, In the rare variant translocations, the translocation is between chromosome 8 and the immunoglobulin light-chain loci on chromosome 22, as shown here, or on chromosome 2. In these cases c-*myc* remains intact on chromosome 8 and is joined to the constant-region locus of one of the two light chains, tail to head, so that both are in the same transcriptional orientation.

One of the many earlier reverses in the attempt to understand c-*myc* activation in Burkitt's cells was the discovery that this transcriptional enhancer is usually separated from the immunoglobulin locus in the translocation, and thus cannot account for the transcriptional activation of the invading c-*myc* exons. Since the c-*myc* exons are activated notwithstanding, it became clear that there must be some other transcriptional activator operating on the immunoglobulin locus. Moreover, because some of the translocations place c-*myc* far away from the constant-region segment, it must operate over a very long range. Croce now believes he has indirect evidence of just such a long-range enhancer.

In hybrids between ST486 and lymphoblastoid cells, in which as a general rule the immunoglobulin genes of both parent cells are expressed, the translocated c-*myc* gene of the ST486 cell is silent — despite having lost its first exon, and thus being freed from any *myc* repressor. Apparently, this gene is not responding to the normal tissue-specific activation signals either for c-*myc* (normally active in lymphoblastoid cells) or for the immunoglobulin genes. Croce interprets this to mean that the putative factors responsible for transcriptional activation of the immunoglobulin locus in lymphomas are absent from the lymphoblastoid cell background; in other words, the activation of the putative long-range enhancer is strictly stage-specific.

The evidence for stage-specificity is strengthened by the behaviour of the reciprocally translocated exon 1 in plasmacytoma cells. In its original Burkitt's lymphoma background, the isolated exon 1 is transcribed, presumably under the influence of the identified immunoglobulin enhancer to which it is tail-to-tail. In plasmacytomas, however, it is silent, while translocated exons 2 and 3 of c-*myc* are transcribed. This is presumably because the enhancer is 'read' only at earlier stages of B-cell differentiation, the longer-range mechanism taking over at the plasma-cell stage and accounting for transcription of the translocated coding exons.

If I had to guess, I should say that exon 1 of the c-*myc* gene will turn out to be critical to the cell-cycle regulation of c-*myc* in its normal context; and that in Burkitt's cells, tissue-specific immunoglobulin gene activators simply override all local c-*myc* controls that might otherwise influence the translocated gene[16]. In short, from investigating c-*myc* regulation in lymphoma cells, we may learn more about the regulation of immunoglobulin genes than about the control of c-*myc* expression. □

Archaeopteryx palaeontological myopia

SIR — Howgate[1] criticizes our interpretations[2,3] of the homologies and morphology of the *Archaeopteryx* manus by distorting and misrepresenting our viewpoints. Palaeontologists have identified the digits of theropods, *Archaeopteryx* and birds as digits 1-2-3 of the primitive reptilian hand whereas embryologists[4-7] have identified the bird digits as 2-3-4. Do the similarities observed by palaeontologists have greater weight than the evidence derived from ontogeny by embryologists?

The correspondence of the number of phalangeal elements in the manus of *Archaeopteryx* with the primitive reptilian formula has convinced palaeontologists that the digits of *Archaeopteryx* represent the digits 1-2-3. We stated that the digits of birds must be 2-3-4 based on embryological work[4,5]. If *Archaeopteryx* is a bird, it should have digits 2-3-4 and not 1-2-3 as suggested by Howgate[1].

Howgate[1] states that we[2,3] resurrected "a broken phalanx hypothesis" proposed by Heinroth[8] which states that there was a break in the proximal phalanx of topographic digit 3 and that we "arrived at a non-theropod phalangeal formula (2-3-3)". We cited Heinroth[8] because it was essential for a complete review. We[2] stated that "The break or joint in the first phalanx of the fourth digit appears immediately distal to the immobilized area". We again stated[3] (p.144) that "either a break occurred in the first phalanx (of the last digit) or if there are two phalanges a distortion of their orientation". We did not conclude that the phalangeal formula of *Archaeopteryx* was 2-3-3, but only stated the possibility of there being a break. Contrary to Howgate[1], only the Berlin and Maxberg specimens have the essential areas of the manus preserved as bone. Their state of preparation precludes a definitive statement of the phalangeal formula of *Archaeopteryx*.

In the left manus of the Berlin specimen there is a laterally directed flange on the first phalanx of the middle digit, directed to the junction of the supposed joint or break. Howgate implied that we[2] said that this flange "served to brace and strengthen the wing"[1]. Howgate[1] further states that "the 'flange' appears to be a secondary outgrowth due to injury or disease and not an original morphological structure". We did not state that this flange could serve to brace the wing since such a small structure cannot brace an entire wing. This functional misconception can only be attributed to Howgate. His illustration of the right manus demonstrates that this area is covered by matrix and a digit. Therefore how can he conclude the flange is an anomaly or a normal structure?

Attempting to make our explanation appear ludicrous, Howgate[1] implies that our "scenario" of the preservation of the fourth digit (its crossing under the third digit) was the result of *Archaeopteryx* "crossing its fingers hopefully as it plunges at high speed in the sea wing-tips first". We stated (as a scenario) that the break or joint in topographic digit 3 was caused by forces during stalling[9,10], impact upon the water, or as a result of preservation. Howgate[1] also stated that "all the specimens of *Archaeopteryx* with a well preserved manus have the second and third digits crossed". This is not the case since the Maxberg specimen[11] has a manus without this condition.

The important aspect of the homologies of the avian manus is the debate between the 1-2-3 and 2-3-4 hypotheses and the implication that different developmental patterns in digit reduction can produce similar morphologies.

Evolutionary unease?

SIR — Peter Fellgett raises an interesting suggestion[1] that the study of cybernetic feedback loops throws light on the redundant (multiple copy) nature of functional genes and hence places the evolution of this phenomenon within the rubric of Darwinian natural selection. His proposition is that selection has favoured organisms in which gene redundancy not only protects them from mutation but also leads to enhanced prospects for survival in that 'a new [biological] program would run rather than crash'. He considers this system of 'selection for selectability' as more acceptable than so-called alternative *ad hoc* suggestions such as molecular drive, which he thinks should only be invoked as additional evolutionary mechanisms if the necessities were demonstrated; the impliction being that selection is our basic null hypothesis.

I have no objection to Fellgett's basic proposition, although I cannot understand his premise that the scientific necessity for alternative mechanisms depends on which side of the Darwinian fence they fall. Molecular drive[2] is based on several well-known processes of non-reciprocal exchange between redundant genes, all of which have the interesting and biologically important effect of continually replacing a family of genes with newly-arising mutant genes, throughout a sexual population. This mechanism of spreading a mutant gene, or parts of genes, can explain the widespread observation of clear differences between species in the way in which families have become replaced (homogenized). The phenomenon has been observed in families of both protein-coding and RNA producing genes and in non-functional DNA families, generally irrespective of the degree of redundancy or chromosomal dispersion of the families. Hence it is extraordinarily difficult to explain by selection alone the parallel homogenization of hundreds of families and the accidental gain and loss of complete subfamilies and families, across any one species, without invoking generally implausible *ad hoc* scenarios. Genetic turnover potentially constitutes an independent mechanism of population change with respect to both the *de novo* origin and the subsequent behaviour of redundant genes. Selection and drift can be expected to interact with this mechanism, depending on the gene family and population structure in question (see refs 2–9).

I am quite comfortable with Fellgett's idea that the origin of redundancy (and I would add the existence of nonreciprocal exchange processes within the redundant families) might be due to selection via cybernetic multiple feedback loops, that is, the processes underlying molecular drive have arisen via natural selection. There is nothing in evolution that cannot be explained by natural selection, if that is our starting point. However, this possibility would need to take into account why so many hundreds of qualitatively different genic and non-genic DNA families exist, why the degree of redundancy varies over several orders of magnitude both for the same family between species and for different families in the same species, why many families differentiate into multiple subfamilies, and why there are continual rounds of family homogenization by variant genes or parts of genes across a species. An unsubstantiated appeal to a seeming Darwinian "selection for selectability" based on cybernetic theory is not a sufficient justification for discounting the necessity for an additional evolutionary mechanism which is based on known DNA turnover mechanisms within the genome. That molecular drive is non-Darwinian is surely irrelevant.

The active site of acidic aluminosilicate catalysts

W. O. Haag, R. M. Lago & P. B. Weisz

Mobil Research and Development Corporation, PO Box 1025 Princeton, New Jersey 08540, USA

The availability of solid acidic catalysts based on zeolite ZSM-5 make possible observations on the nature and the absolute rate behaviour of the individual protonic sites. Tetrahedral aluminium atoms are the highly reactive ingredients, even at levels of parts per million, or less. Turnover numbers for several hydrocarbon reactions equal and exceed familiar enzymatic turnover values. Intensive catalytic activities can result from aluminium levels likely to be ignored by the experimenter.

THE acid catalytic activity of aluminosilicates is usually assumed to reside in sites involving tetrahedral aluminium atoms in substitutional positions in the framework of silica; the negatively charged aluminium sites are associated with cations which, in the case of acid catalysts, are protons. It has, however, been difficult to identify and count the number of active sites, and thus to determine quantitatively the turnover rate of which these sites are capable. With the availability of zeolitic catalyst, and particularly of ZSM-5 catalysts, such a quantitative description is now possible.

For many decades, acidic clays and amorphous silica–alumina compositions have been used to catalyse the cracking of carbon–carbon bonds, for alkene isomerization and polymerization, aromatic alkylation with alkenes or alcohols, transalkylation, and other acid-catalysed reactions. The cracking of alkanic bonds requires the highest activity; alkene transformations require lower catalytic strength and/or lower temperature.

Activity of aluminosilicates

A convenient measure of activity is based on the alpha (α)-test[1,2] which has been refined[3]. It consists of measuring the first-order rate constant for the cracking of *n*-hexane at 538 °C at 100 mm Hg. For comparing relative activities, $\alpha = 1$ corresponds to the activity of a high surface area (420 $m^2 g^{-1}$) amorphous silica–alumina catalyst (10 wt% Al_2O_3 content), which has a first-order rate constant for *n*-hexane cracking of $k = 0.067\ s^{-1}$. This corresponds to a reaction rate ($dn/dt = kc$) of 1.3×10^{-7} mol $s^{-1} g^{-1}$ of catalyst characteristic of highly active catalyst particles in commercial petroleum cracking.

By definition, k is the inverse of a residence time (for 63% conversion). Previously[2], we have used the superficial residence time, based on vapour flow rate into the reactor measured at room temperature, and the bulk catalyst volume; this gave a rate constant of $0.016\ s^{-1}$. This is convenient when relative activities (α) are to be determined for practical reactor operations. To describe an absolute rate, we use the more accurate value based on vapour flow in reaction conditions (538 °C) and on unit weight of catalyst.

As the above catalyst contains about 0.002 mol of Al g^{-1}, the turnover rate above corresponds to only 4×10^{-3} molecules min^{-1} per atom of total aluminium in the sample. However, the fraction of the Al atoms which are both accessible and in the proper chemical condition (tetrahedral substitution in silica structure) is unknown.

With the zeolites as catalytic solids, we have progressed from solids with a, usually unknown, number of active sites available on the geometric particle surface to an essentially 'transparent' medium: all intra-crystalline sites can be available for molecular contact.

With zeolite Y in the hydrogen (protonic) form, α activities of between 1,000 and 5,000 and higher were observed[1,2]. This implies a turnover capability of the order of 2–10 molecules min^{-1} per Al atom. However, the equivalence and degree of participation of all Al atoms was not clear in view of the high aluminium atom density in this zeolite, approximately one Al atom for two Si atoms, and the ease with which aluminium can undergo hydrolysis and removal from the framework.

Physical chemistry of ZSM-5

In contrast to zeolites previously used as catalysts, the aluminium atom concentration in zeolite ZSM-5 is very low and continuously variable over many orders of magnitude, as illustrated by Fig. 1. The representation of aluminium concentration when expressed in terms of the SiO_2/Al_2O_3 ratio traditionally adopted to characterize zeolite mineral structures, demonstrates the variability and unique diluteness of Al-atom concentration achievable for ZSM-5.

The factor of most physical chemical significance is that, in ZSM-5, Al atoms are no longer structure-determining constituents, that is, they no longer contribute a major portion of the framework structure[3].

The average distance between aluminium sites is equivalent to several to many atomic diameters, and their distribution should approach randomness. It has been observed[4] that a random model (subject only to the proviso of Loewenstein's rule) may be applicable to a zeolite at Si/Al ratios greater than a value of 2.0.

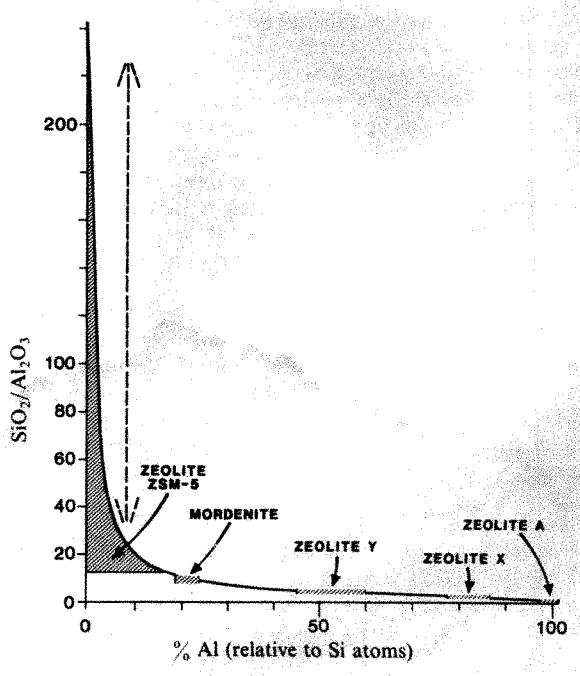

Fig. 1 Al atom concentration and SiO_2/Al_2O_3 ratio for various zeolites.

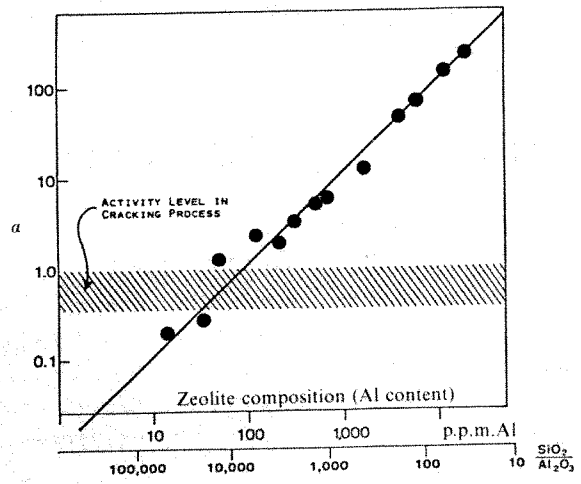

Fig. 2 The hexane cracking activity plotted against the aluminium content in HZSM-5. Shaded band indicates activities near $\alpha \simeq 1$.

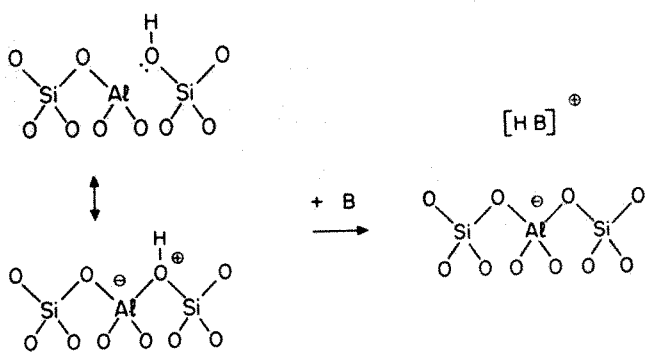

Fig. 3 The Brønsted acid site in HZSM-5 and its interaction with a base.

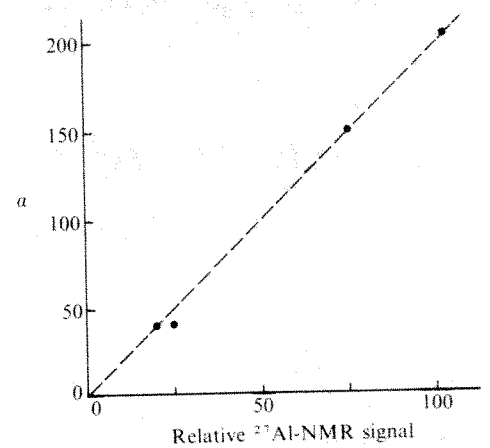

Fig. 4 The activity of HZSM-5 plotted against the tetrahedral aluminium NMR signal.

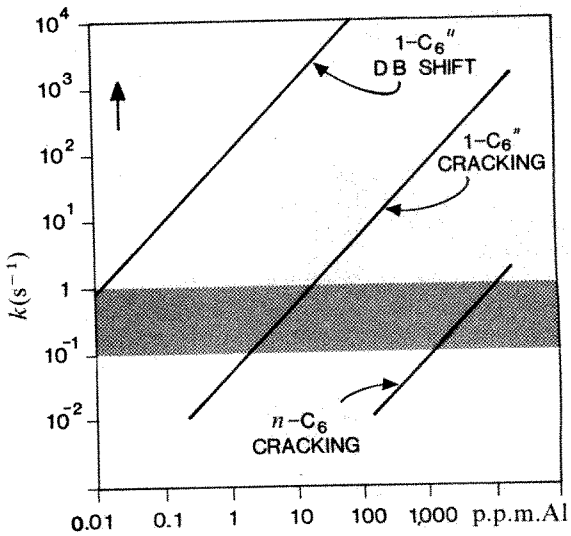

Fig. 5 Comparison of rate constants at 454 °C, of hexane cracking, hexene cracking, and hexene double-bond (DB) shift (after ref. 18).

Elementary statistics indicate that in an assembly of 96 T-atoms (Si or Al), which define a unit cell of the ZSM-5 structure, a fraction of approximately 14% of all unit cells would have no Al atoms, when the average Si/Al ratio R of the sample is 48, according to $f=[1-1/(R+1)]^{96}$. Conversely, for a ZSM-5 zeolite of a higher average Si/Al ratio of, say, 120, about 20% of its unit cells can be expected to have a Si/Al ratio of <50.

These calculations apply rigorously to samples with a macroscopically homogeneous aluminium distribution, both within the individual crystallites and within the sample. Some authors[5–7] have reported Al gradients in their samples. For such samples, with average Si/Al value R, statistics will produce some deviation of Al frequency per unit cell entity in both directions.

In all cases, it will become apparent from the catalytic data that the Al atoms in ZSM-5 occur at sufficiently low concentration to be analogous to a dilute solution. There is substantial chemical uniformity of sites. (This does not rule out topologically different locations in the ZSM-5 framework, as they involve characteristic distances beyond the range of localized chemical forces.)

C–C bond cracking activity per site

The α activity is proportional to Al contents and extrapolates to zero for aluminium concentration tending to zero[3]. This dependence has now been extended over nearly four orders of magnitude of both activity and Al concentration, down to nearly 20 p.p.m. of Al, as seen in Fig. 2. For orientation, activities near and below $\alpha \sim 1$ correspond to levels actually used by industrial processes.

The active Brønsted acid site in a hydrogen zeolite and its interaction with a base or substrate is depicted in Fig. 3. Magic-angle spinning (MAS)–NMR data have shown[8] that in the dehydrated state aluminium is in a tetrahedral environment which is asymmetric, in agreement with Fig. 3 (left-hand side). On interaction with an added base, B, such as water[8] or ammonia[9], the aluminium is in a highly symmetrical tetrahedral coordination[8], as indicated in Fig. 3 (right-hand side).

A meaningful quantitative correlation of activity with total aluminium content can be expected only when all Al atoms are in tetrahedral framework positions. Hydrolysis to give extra-lattice Al is frequently observed in zeolites with low Si/Al ratio such as zeolite Y[10]. In HZSM-5, this can be readily prevented by preparing the sample in conditions that avoid undue exposure to heat and water vapour[3], as has been pointed out elsewhere[11,12]. Also, thorough replacement of sodium ion must be assured, as its concentration must be only a small fraction of the already small Al concentration.

The complete proportionality of activity and number (concentration) of Al atoms is consistent with the homogeneity of the active sites achieved in this state of dilute solution.

This and the existence and stability of a single protonic Al site in HZSM-5 is also supported by and consistent with the following independent observations:

(1) Examination of the Al atoms using high-resolution MAS–NMR techniques[13] has demonstrated that all aluminium incorporated during synthesis of ZSM-5 zeolite, even at the lowest level of incorporation in the synthesis, is tetrahedral in structure.

(2) In carefully prepared samples there is a single hydroxyl band, independent of the Si/Al ratio, centred at 3,603 cm^{-1} in

the IR spectrum assigned to Brønsted acid sites[12], and the intensity is proportional to Al content. A second IR hydroxyl band at about 3,720 cm^{-1} is due to crystal terminating OH groups or to silica gel impurities[12,14].

(3) The ammonium form can be quantitatively reconstituted and no Lewis-bound pyridine can be found by IR[12], that is, all Al atoms in the zeolite framework are in tetrahedral coordination.

(4) Measurements of the ion exchange capacities of a series of HZSM-5 samples with various Si/Al ratios show a 1:1 molar ratio of the exchanged cation, caesium, to the aluminium content[3].

(5) The temperature-programmed desorption (TPD) spectrum of ammonium-exchanged ZSM-5 shows a single high-energy desorption band with T_{max} at 400 °C as observed by Kerr and Mikovsky, and others[14]. Kerr and Mikovsky (unpublished data) have shown that it is not composed of a multitude of bands resulting from ammonia elimination from acid sites of different acidity, as is found with HY zeolite[15]. The molar amount of ammonia eliminated is equal to that of the chemically determined total aluminium concentration for a series of HZSM-5 samples[9]. After exposure to excess ammonia vapour, the ammonium form desorbs ammonia from two additional lower energy states, giving rise to three desorption maxima, that are sometimes erroneously thought to indicate the presence of three types of acid site[16,17].

We can now demonstrate in Fig. 4 the proportionality of α activity to the tetrahedral Al concentration, as determined by MAS–NMR[9]. Clearly, the tetrahedral Al atoms (Fig. 3) and their associated protons constitute the active site.

With such quantitative data for the number of active sites available, absolute molecular turnover rates and numbers can now be determined.

The absolute turnover rate for *n*-hexane cracking at the standard test conditions (538 °C, 100 torr *n*-hexane pressure) is calculated to be about 2.8 molecules min^{-1} per atom of Al, for the entire Al concentration range.

We find that the reaction rate is indistinguishable from first order for the entire pressure range 10–760 torr. Therefore, the fraction of occupied Al sites at the pressure of measurement (100 torr) must be <1% of all Al sites. It follows that the turnover rate per occupied active site (the turnover number) is greater than 300 molecules min^{-1} per active Al site.

Acid-catalysed turnover rates

The intrinsic rate constants for many other acid-catalysed reactions are proportional to the α of the ZSM-5 catalysts, and therefore to the number of Al atoms; they include the rates for toluene disproportionation, xylene isomerization, alkene conversion and methanol conversion[18]. These rates are all greater than the alkane cracking rate.

Figure 5 compares the reaction rates we have observed for *n*-hexane cracking, 1-hexene cracking, and 1-hexene double bond isomerization. Each absolute rate was found to be proportional to tetrahedral aluminium concentration, as shown by the parallel lines. The alkene cracking rate is some 800 times the alkane cracking rate, and the alkene isomerization is some 1,300 times the alkene cracking rate.

Many commercial processes occur at a liquid hourly space velocity (LHSV) of 1–10, that is, they occur with a rate constant $k \approx 0.1$–$1\ s^{-1}$. Thus, the site concentration needed for achieving such technically relevant reaction rates—a magnitude indicated by the shaded area in Fig. 5—can be below 1,000 p.p.m. Al for alkane conversion, and as low as a fraction of a p.p.m. to 100 p.p.m. for various other conversions such as those involving alkenes. Hence 'discoveries' of significant but unexpected catalytic activity on siliceous zeolite compositions can occur due to ignorance of the role of unanalysed amounts of lattice aluminium.

Table 1 The magnitudes of the turnover values for ZSM-5 at 454 °C, 100 torr

	Turnover rate (molecules min^{-1} per Al site)	Turnover no. (molecules min^{-1} per active Al site)
n-hexane cracking	0.37	>37
1-hexene cracking	290	>29,000
1-hexene double-bond isom.	370,000	$\geq 4 \times 10^7$

From data of Lago and Haag; see ref. 18.

Table 1 presents the magnitudes of the turnover figures at 454 °C, expressed in the units (min) characteristic of enzymology. (These magnitudes are large and not dissimilar from those encountered in enzyme catalysis.)

Experimental procedures

The samples of HZSM-5 were prepared[19] and pretreated[3] according to published procedures. Total aluminium was determined by digesting the zeolite in a HF/H_2SO_4 mixture, evaporating to dryness, dissolving the residue in hydrochloric acid and, after addition of potassium chloride as an ionization and interference suppressant, analysing by atomic absorption spectrometry. The accuracy of the Al analysis depends on the concentration in the original sample with the following uncertainties: for 1,000, 100 and 25 p.p.m. Al—5%, 10% and 25%, respectively.

The concentration of framework tetrahedral aluminium was determined quantitatively by ^{27}Al MAS–NMR using a JEOL FX-200 Fourier transform spectrometer. Details of the technique will be published elsewhere[9].

Conclusions

It has been experimentally demonstrated that the catalytic site for acid catalysis on aluminosilicate catalyst is quantitatively identifiable with a protonated tetrahedral aluminium atom in the SiO_2 framework.

The number of sites and associated acid activities have been determined, using ZSM-5 zeolites of varying Al concentration, from which absolute turnover rates and numbers are now available. These resemble in magnitude the enzymatic turnover numbers.

Careful control and quantitative knowledge of minute Al concentrations is essential in experimentation and interpretation of catalytic observations on ZSM-5 structures and other zeolites. If ignored, the results are likely to be erroneously attributed to other phenomena or components.

If we assume that the active sites in standard amorphous silica–alumina catalysts are similar in nature and specific activity to those in ZSM-5, then the above data indicate that only about 1 out of 1,000 of the analysed Al atom was effectively involved in such catalysts.

Effect of somatic mutation within translocated c-*myc* genes in Burkitt's lymphoma

T. H. Rabbitts*, A. Forster*, P. Hamlyn† & R. Baer*‡

* MRC Laboratory of Molecular Biology, and † Ludwig Institute for Cancer Research, MRC Centre, Hills Road, Cambridge CB2 2QH, UK

Our previous studies of a translocated c-myc *gene in the Raji Burkitt's lymphoma cell showed somatic mutations in exons 1 and 2. We have extended these observations to two other translocated* c-myc *genes and find a common occurrence of mutation in the noncoding exon 1. We also found that in Raji cells, unlike other Burkitt's lymphoma cell lines, the normal allele of the* c-myc *gene is transcribed as well as the translocated gene. These results support a model in which* c-myc *oncogene activation in Burkitt's lymphoma occurs by disruption of a normal transcriptional control mechanism in which the* c-myc *protein is itself involved.*

BOTH human Burkitt's lymphoma (BL) and mouse myeloma cells display specific chromosomal translocations involving immunoglobulin gene loci and the c-*myc* proto-oncogene[1–7]. In Burkitt's lymphoma there are three types of translocation involving the c-*myc* gene on the long arm of chromosome 8 (8q24). These frequently involve the immunoglobulin heavy (H)-chain locus (14q32) and less frequently, in the so-called variant Burkitt's lymphoma, involve either the κ light (L)-chain locus (2p12) or the λ L-chain locus (22q11)[8]. Somatic cell genetics[9] and *in situ* hybridization studies[10] established that in t(8; 14) the c-*myc* gene is carried into the $14q^+$ aberrant chromosome where it becomes associated with the H-chain constant (C)-region genes in the opposite orientation for transcription[6,7,11,12]. Frequently this translocation to chromosome 14 does not affect the three-exon structure of the c-*myc* gene nor does the breakpoint occur near to the c-*myc* gene transcriptional promoter[6,12]. A more dramatic variation in the breakpoint relative to the c-*myc* gene has been reported in the variant BL translocations where it occurs downstream (3′) of this gene[10,13–16]. In contrast, the analogous translocation of the mouse c-*myc* gene and the *Igh* locus very frequently results in complete or partial loss of the c-*myc* gene exon 1 (refs 2, 4, 17).

In view of this variability in the translocation breakpoint with respect to the c-*myc* gene in Burkitt's lymphoma and mouse myelomas, the possibility must be considered that, assuming the translocation activates the oncogenic potential of the c-*myc* gene, controlling elements normally involved in immunoglobulin gene transcription take control of the translocated c-*myc* gene. The possibility of higher levels of transcription resulting from translocation does not seem to be the whole answer because we were unable to demonstrate elevated levels of c-*myc* messenger RNA (mRNA) transcription in BL cell lines compared with lymphoblastoid or other tumorigenic cell lines[6]. Furthermore, a clearly demonstrable enhancer element near the human C_μ gene does not remain on the $14q^+$ chromosome in many cases of t(8; 14)[18] and therefore cannot control this gene transcription in these cases. As no obvious general effect could be observed on the c-*myc* gene in Burkitt's lymphoma, we investigated the possibility that alterations in the existing elements for controlling the c-*myc* gene are important rather than the acquisition of new elements after translocation. This focused our attention on exon 1 of the c-*myc* gene, which has no assigned function, being transcribed but not translated into protein[6,19,20] although it has been suggested to have a regulatory role[21]. Recently, we described the nucleotide sequence of the translocated c-*myc* gene from Raji cells t(8; 14) and found substantial alterations in the sequence (both base changes and deletions) of the first two exons[22]. The changes observed in Raji exon 2 would result in a substantially altered c-*myc* protein product, but no somatic mutations were reported to be present in another translocated c-*myc* gene sequenced recently[7]. These data suggested the possibility that changes in the sequence of exon 1, rather than coding-region segments, may be important in the activation of the c-*myc* gene. We now report the sequence of the 5′ end of a Daudi c-*myc* cDNA clone[6] which must derive from the translocated c-*myc* gene as only this allele of c-*myc* is active in Burkitt's lymphoma[12,23]. This sequence differs from the normal exon 1 by 7% of base substitutions. Furthermore, the sequence of the translocated c-*myc* gene exon 1 from the variant BL cell line LY67 [t(8; 22)] was also found to contain base substitutions. In addition, we have observed that the normal c-*myc* gene is expressed in Raji cells (which possess a substantially altered translocated c-*myc* gene-coding segment), unlike the analogous gene in the majority of BL cell lines. This result supports a transcriptional control mechanism using, directly or indirectly, the c-*myc* gene product.

Variable translocation point

In the cell lines studied here [Daudi, t(8; 14); JI and LY91, t(2; 8); MAKU and LY67, t(8; 22)], we were unable to detect rearrangements of the c-*myc* gene using an exon 2 probe (M13JI1.5Sac)[6] in Southern filter hybridization with *Eco*RI or *Bam*HI-digested DNA (data not shown). Several c-*myc*-containing λ phage clones (see Fig. 1), were isolated from phage libraries prepared from BL DNA and a detailed restriction map of the c-*myc* locus was constructed covering approximately 8 kilobases (kb) upstream of exon 1 and 14 kb downstream of exon 3. Two subclones were prepared (pUCJI5R4 and pUCJI7BS8) (Fig. 1) and used in filter hybridizations with either *Bgl*II-digested genomic DNAs (pUCJI5R4) or *Sac*I-digested DNAs (pUCJI7BS8). The choice of these two restriction enzymes allows us to overlap the DNA segments detected by the exon 2 hybridization probe and therefore assay for possible DNA rearrangements which have occurred on the flanking sides of the probes. We only detected unrearranged restriction fragments with either probe (6.5-kb *Bgl*II fragment and 7.7-kb *Sac*I fragment) as evidenced by the similarity between all of the DNAs compared (Fig. 1). As we know that the translocation point is upstream of the c-*myc* gene in Daudi cells[11], these hybridization data place the translocation point at least 12 kb upstream of this c-*myc* gene, in agreement with results reported by others[11,12]. Conversely, as the breakpoint is on the 3′ side of the c-*myc* gene in variant BL cells, the lack of rearrangement present in *Sac*I-digested DNA from JI, LY91, MAKU and LY67 shows the translocation point to be >14 kb downstream of the c-*myc* gene in these cells. Due to the remarkable variability between the c-*myc* gene and the translocation breakpoint in Burkitt's lymphoma[24] (see Fig. 1), none of the clones obtained from the

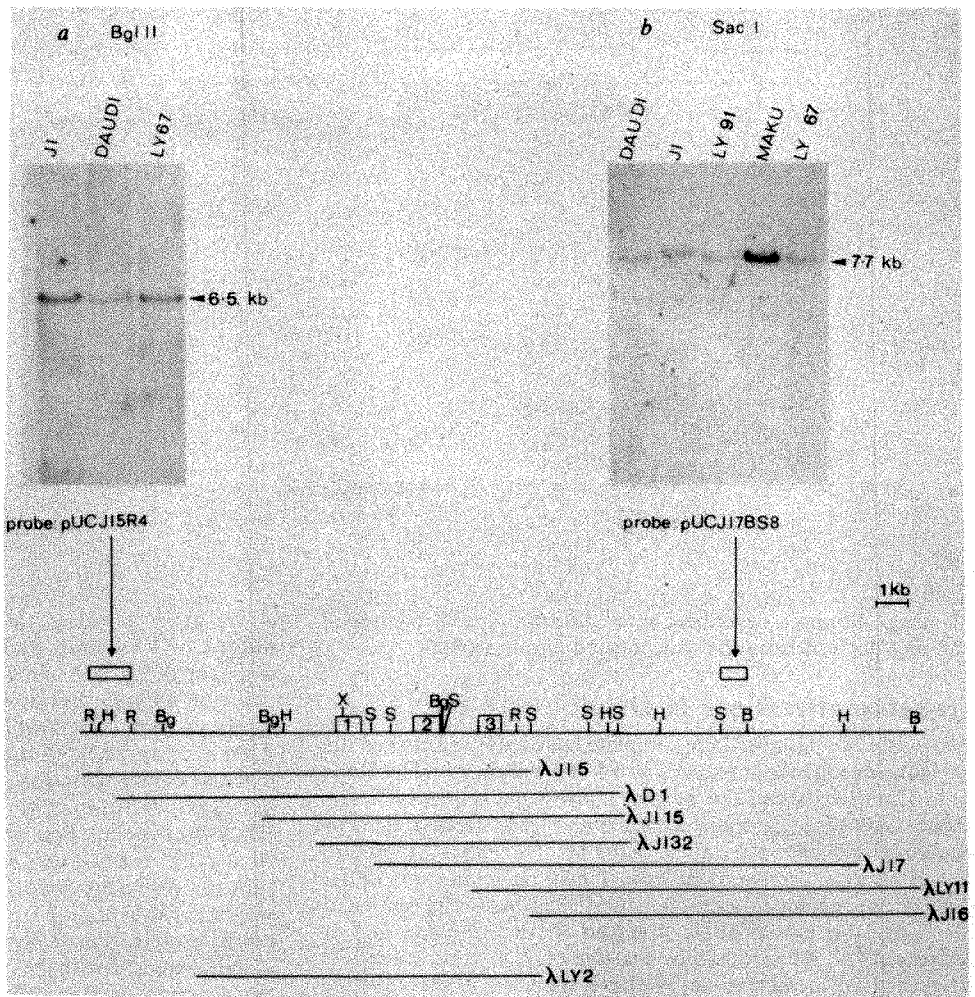

Fig. 1 Filter hybridization of Burkitt's lymphoma DNA using c-*myc* flanking region probes. The restriction map shown for the c-*myc* locus was generated from the λ phage derived from genomic libraries of JI and LY67 DNA (cloned in λ2001; ref. 34) and Daudi DNA (cloned in λ1059; ref. 34). The extent of each of these clones is indicated below the map (λJI7 has been described previously[22]). Two subclones used in this study, cloned in the pUC8 vector, were pUCJI5R4 containing a 1.2-kb *Eco*RI fragment from the 5′ end of the region and pUCJI7B58 containing a 0.8-kb *Bam*HI–*Sac*I fragment. These probes were nick-translated and used in Southern filter hybridizations[35] of *Bgl*II-digested DNA (pUCJI5R4, *a*) or *Sac*I-digested DNA (pUCJI7B58, *b*). Hybridization conditions were 2×SSC, 10% dextran sulphate, 0.2% polyvinylpyrrolidone (PVP), bovine serum albumin (BSA) and Ficoll[36], 0.1% SDS, 50 μg ml^{-1} fragmented salmon DNA containing 10^6 c.p.m. ml^{-1} probe (specific activity ~10^8 c.p.m. μg^{-1}); after hybridization, filters were washed with 0.1× SSC, 0.1% SDS and autoradiographed at −70 °C with prefogged film[37]. Restriction fragment sizes were determined by comparison with λ phage DNA cut with *Hin*dIII. R, *Eco*RI; H, *Hin*dIII; Bg, *Bgl*II; X, *Xho*I; S, *Sac*I; B, *Bam*HI; *Bgl*II sites are not complete.

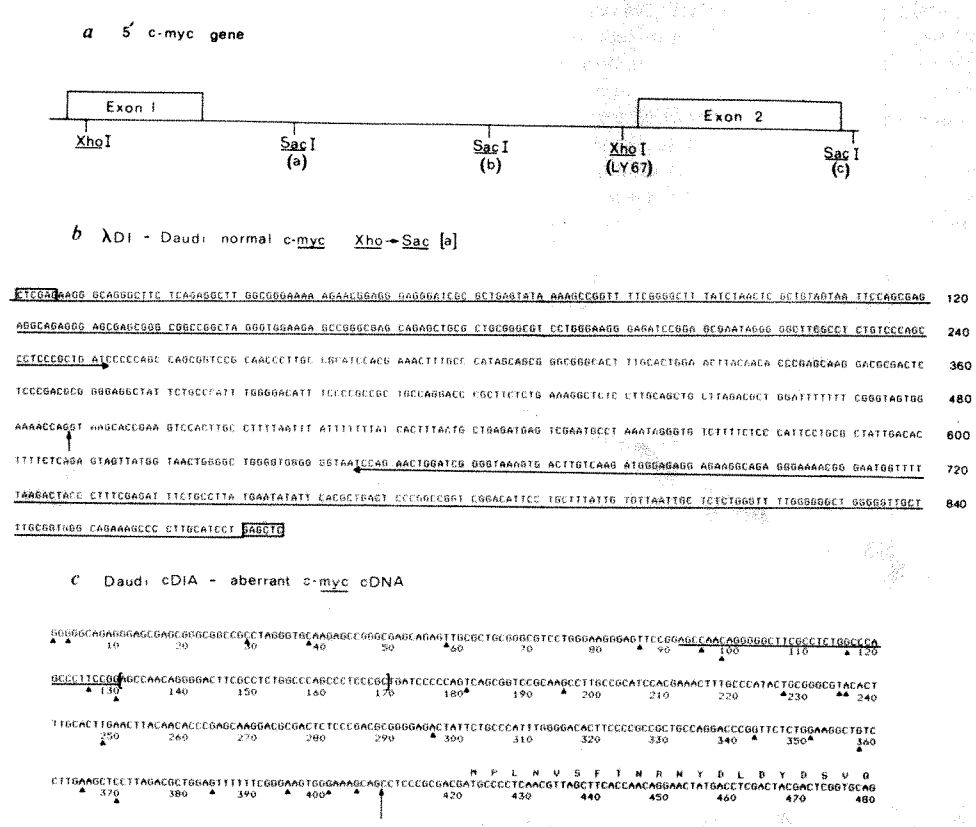

Fig. 2 Nucleotide sequence of exon 1 from the Daudi c-*myc* gene. *a*, Partial restriction map of c-*myc* exons 1 and 2. The *Sac*I site indicated as *Sac*I(a) is absent from clone λLY2 and the *Xho*I site near exon 2 is unique to λLY2. *b*, Exon 1 sequence of λD1 Daudi c-*myc* gene. *Xho*I and *Sac*I sites at the ends of the sequenced fragment are boxed. The vertical arrow indicates the RNA splicing signal. The underlined regions indicate sequences obtained from the analogous region of λJI5 and λJI15. Nucleotide sequences are obtained from random sonicated fragments subcloned in M13mp8 followed by sequencing by dideoxy chain termination methods[38]. *c*, 5′ end sequences of Daudi cDNA clone, pUC cDIA. The sequence variations observed for pUC cDIA[22] are indicated by small arrowheads (the 5′ G residues may have been introduced by cloning procedures); the large vertical arrow indicates the RNA splice site. The underlined region is a duplicated segment present in the adjacent bracketed section.

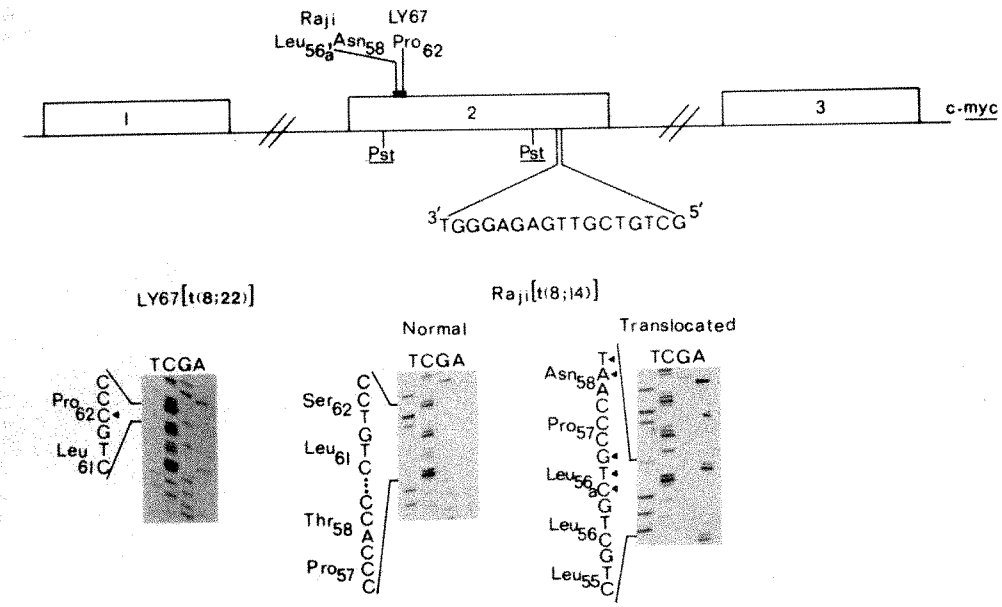

Fig. 3 cDNA cloning strategies and sequences from LY67 and Raji clones. A synthetic oligonucleotide (sequence shown beneath a diagrammatic representation of the c-*myc* genomic gene arrangement) was used to prepare double-stranded cDNA as described previously[39] from poly(A)-selected RNA obtained from post-nuclear supernatants. After digestion with *Pst*I, fragments were cloned into *Pst*I-digested M13mp8 and screened[40] for the presence of c-*myc* exon 2 sequences using a radioactively labelled *Sac*I fragment isolated from the clone M13JI71.5Sac[22]. Positive clones were directly sequenced by dideoxy chain termination procedures. The c-*myc* gene diagram indicates the position of amino acid substitutions found in LY67 and Raji genes as well as the *Pst*I sites used in the cloning, and representative areas of sequence are shown from the cDNA clones together with the base changes (indicated by arrows) present in altered versions.

BL phage libraries described here could be directly identified as being derived from the translocated chromosome.

Sequence alterations in Daudi c-*myc* cDNA

Previously, we described the complete concordance between the nucleotide sequence of exons 2 and 3 of c-*myc* in a cDNA clone from Daudi cells and the normal c-*myc* gene sequence[22]. The observation that the translocated c-*myc* gene from Raji cells contained sequence alterations in the first two exons[22] therefore suggested that alterations in exon 1 may be important (rather than coding region alterations). As it has been demonstrated that only the c-*myc* allele involved in the translocation is expressed[12,23], we can assume that the cDNA clone is derived from the translocated allele. We have, therefore, sequenced the exon 1 region of the Daudi cDNA clone and found that it contains multiple base differences compared with the sequence of exon 1 derived from the normal c-*myc* gene isolated from a phage library of Daudi DNA (included in a *Xho*I–*Sac*I fragment; see Fig. 2*a*). The latter sequence agrees with the exon 1 sequence of other normal c-*myc* genes[7,22,25] and those regions underlined in Fig. 2*b* were also sequenced in c-*myc* clones from JI phage clones and found to contain no sequence differences. This suggests that we are not merely detecting polymorphism of the human c-*myc* exon 1 sequence. The distribution of base alterations in the Daudi cDNA exon 1 is indicated in Fig. 2*c*, as well as the presence of a 35-nucleotide duplicated region (starting at residue 92). The overall difference between the cDNA and normal exon 1 sequences is 7.3% (excluding the duplication) but no obvious significant pattern of these base changes is apparent from this sequence. These data argue, however, that the differences observed in the Daudi cDNA exon 1 sequence result from mutations introduced into this region during the translocation event.

Markers for translocated c-*myc*

As discussed for the data in Fig. 1, those variant BL cell lines available for study did not show obvious c-*myc* gene rearrangement when analysed by filter hybridization and therefore did not provide us with phage clones which were obviously derived from the translocated chromosome. We therefore adopted an indirect strategy for the identification of the translocated c-*myc* gene which relies on the critical observation that the normal c-*myc* allele is transcriptionally silent in Burkitt's lymphoma[12,23]. Thus, the c-*myc* mRNA in BL cells should come from the translocated allele, and it follows that cDNA clones made from this mRNA will represent the sequence of this translocated c-*myc* gene. We have, therefore, prepared cDNA clones from mRNA of LY67 and Raji cells using the procedure indicated at the top of Fig. 3. A 17-residue long oligonucleotide (designated common oligonucleotide—see Fig. 5) was used to prime cDNA synthesis from a site near the 3′ end of exon 2 in the c-*myc* gene. After making the DNA double-stranded with DNA polymerase, it was cleaved with *Pst*I (for which sites occur in exon 2 as indicated) and cloned in the vector M13mp8 (ref. 26) for direct DNA sequencing. Six independent cDNA clones were made from LY67 mRNA and each of these clones showed a T to C substitution in the codon for amino acid 62. This substitution would yield a proline instead of serine at this position in the c-*myc* protein; Fig. 3 compares the relevant area of the LY67 cDNA sequence with the normal sequence derived from a cDNA clone present in Raji cells (this clone is discussed below).

The presence of a proline codon substitution in the LY67 cDNA provides a sequence marker for the translocated c-*myc* gene in this cell line. By comparing this sequence with genomic clones derived from LY67 DNA, we found that the clone λLY2 (see Fig. 1) contained this change and therefore conclude that this genomic DNA insert was representative of the c-*myc* gene involved in the translocation in this cell. An indication of possible sequence differences at the 5′ end of the genomic insert within λLY2 was given by two restriction enzyme site polymorphisms found in the intervening sequence between exons 1 and 2. These are the acquisition of a new *Xho*I site (resulting from an A→G transition) 49 bases from the ATG codon (shown in Fig. 2*a* and Fig. 4) and the loss of a *Sac*I site shown as *Sac*I(a) in Fig. 2*a*.

The strategy for sequencing the relevant regions of λLY2 was to subclone the 2-kb *Xho*I fragment (containing exon 1) in pUC8 and the 1.5-kb *Sac*I fragment (containing exon 2) into M13mp10, followed by fragment isolation for generation of randomly overlapping clones. A partial sequence of the segment from the 5′ *Xho*I site to the *Sac*I(c) site (see Fig. 2*a*) of the λLY2 insert is shown in Fig. 4. The only nucleotide alteration, compared with normal c-*myc* gene sequences, found in exon 2 is the single base change identified in the cDNA clones. Further nucleotide substitutions begin to appear in the intervening sequencing between exons 1 and 2, and multiple differences exist within exon 1 itself. Interestingly, in this case the base substitutions are confined to the 3′ half of exon 1, in marked contrast to the overall spread of changes found in exon 1 of Daudi and Raji cells. Furthermore, sequence data of the promoter region of the LY67 translocated c-*myc* gene revealed no base substitutions compared with the normal sequence (unpublished results). A possible significant feature of these findings is that in three cases of translocated

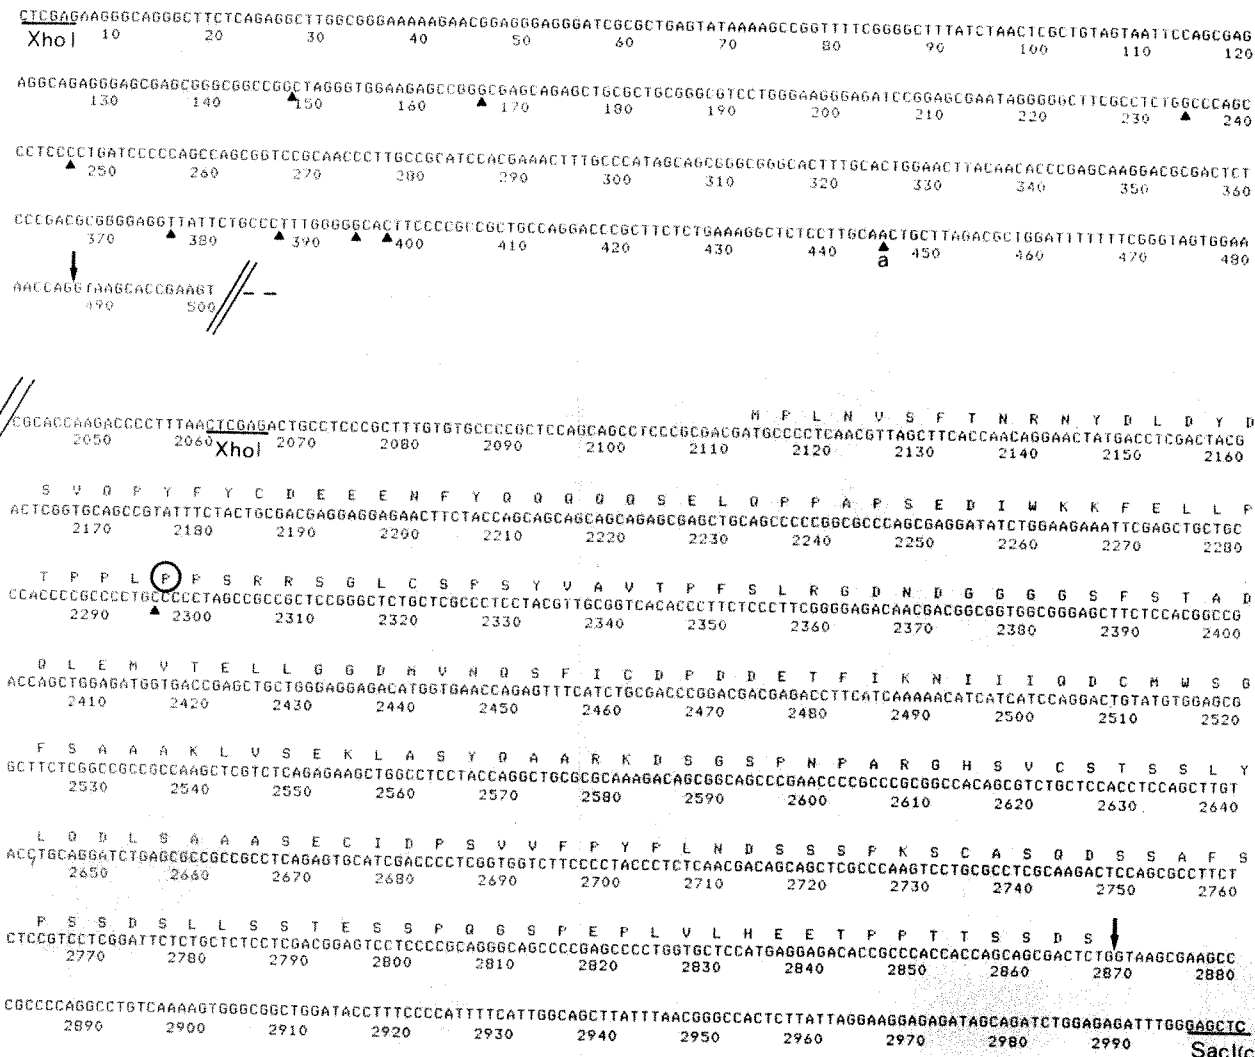

Fig. 4 Partial nucleotide sequence of the aberrant c-*myc* gene derived from λLY2. The nucleotide sequence is shown from the *Xho*I site to the *Sac*I(c) site (Fig. 2) of λLY2. Sequence data were obtained from random sonicated subclones in M13mp8 or subclones derived from either *Pvu*II, *Taq*I or *Alu*I digestion of a clone containing the 2-kb *Xho*I fragment (indicated in Fig. 2) in pUC8 (pUCLYXh16). Base substitutions within exon 1, compared with normal c-*myc* (Fig. 2), are indicated by small arrowheads and deletions are indicated by arrowheads between bases (deletions a and b are 2- and 3-base pair deletions respectively; the former results in the destruction of a *Pvu*II site). The proline substitution in exon 2 is circled. Restriction sites are as indicated in Fig. 2 (the *Sac*I(a) site is absent from λLY2 and the *Xho*I site at position 2,061 is unique to λLY2). The RNA splice sites are marked by large arrows.

c-*myc* genes (those of Raji, Daudi and LY67 cells), exon 1 is altered compared with the normal sequence (see below).

Normal c-*myc* is transcribed in Raji cells

Usually, the unrearranged c-*myc* gene is transcriptionally silent in Burkitt's lymphoma[2,23], strongly implying a direct transcriptional control of the c-*myc* gene which is, however, lost from the translocated allele. As this effect seems to be related to the product of the c-*myc* gene, it would be of considerable interest to study the effect of mutants in the c-*myc* protein on c-*myc* gene transcription. Potentially, the product of the translocated c-*myc* gene in Raji cells represents such a situation as it has been shown that exon 2 (the first coding exon) contains several codon substitutions. Therefore, we have prepared cDNA clones from Raji mRNA to investigate the possibility that the normal c-*myc* allele is active in the presence of an altered gene product. Two cDNA clones were prepared (see Fig. 3) and the sequences revealed that one of these clones derived from the translocated c-*myc* gene, as it contained the characteristic base changes present in this gene, while the other cDNA clone derived from the normal allele. Figure 3 includes relevant sequences from these clones, showing the regions of interest. The analysis of only two cDNA clones from Raji does not allow any real estimate of the relative proportions of transcription (or of translation) from the respective c-*myc* genes. We therefore undertook to estimate the relative level of c-*myc* gene transcription in Raji cells using oligonucleotides which either detect both the normal and translocated c-*myc* mRNA (common oligonucleotide) or detect only the translocated c-*myc* mRNA (Raji-specific oligonucleotide) in Northern mRNA filter hybridizations. Figure 5 shows the results of this type of experiment; Fig. 5*a* illustrates the 17-long oligonucleotides used and their corresponding locations in exon 2 of c-*myc*. The common oligonucleotide is the one used for the cDNA cloning experiment and the Raji-specific oligonucleotide spans the region of sequence (illustrated in Fig. 3) which includes the additional leucine codon and the Thr→Asn substitution (position 58). (Thus, the Raji-specific oligonucleotide contains 5 out of 17 bases different from the normal c-*myc* sequence, including a 3-base insertion.) With these oligonucleotides as labelled probes for Raji or JI [t(2;8)] mRNA, we detected hybridization of c-*myc* mRNA in both mRNA populations using the common oligonucleotide (Fig. 5*b*) but only c-*myc* mRNA in Raji using the Raji-specific primer, thereby confirming that the latter probe only detects the Raji translocated c-*myc* mRNA in these hybridization conditions. For a quantitative estimation of the contribution of normal or translocated c-*myc* mRNA in Raji cells, the filters were rehybridized with a c-*myc* cDNA clone to allow analysis of the two sets of data by

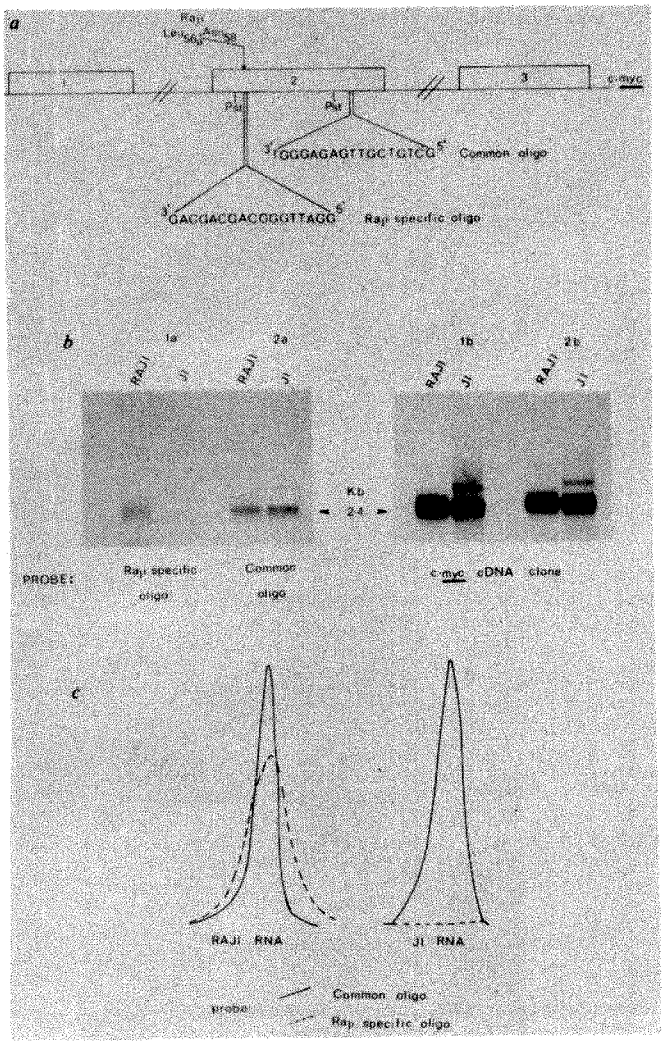

Fig. 5 Northern filter hybridization with c-*myc* oligonucleotide probes. *a*, Diagram of the location and sequence of the common c-*myc* complementary oligonucleotide (the same as used in Fig. 3) and the Raji translocated c-*myc* specific oligonucleotide. *b*, Autoradiographs of filter hybridizations using the various probes indicated. Two aliquots of 50 μg Raji and two of 10 μg JI poly(A)-containing RNA were glyoxylated[41] and run in parallel on a 1.4% agarose gel, followed by electrophoresis and transfer to cellulose nitrate[41] to yield two identical filters, each containing Raji and JI RNA. The filters were hybridized with ^{32}P-end-labelled oligonucleotides at 37 °C for 18 h in 2×SSC containing 0.2% PVP, BSA, Ficol[36], 0.1% SDS and 50 μg ml^{-1} sonicated, denatured salmon sperm DNA. After hybridization the filters were washed at 37 °C with 2×SSC, 0.1% SDS (six times for 10 min each), followed by autoradiography at −70 °C with prefogged film[37]. When the autoradiograph had been obtained, both filters were rehybridized with a cloned c-*myc* probe, pUC cDIA[18]. The relative quantities of RNA in the autoradiographs were assessed by densitometry. *c*, Densitometer tracings from Raji and JI RNA hybridized with the two c-*myc* oligonucleotides.

densitometry; the densitometer tracings of the oligonucleotide hybridizations for JI and Raji mRNA are given in Fig. 5*c*. Taken at face value, the proportion of signal in c-*myc* mRNA from the translocated gene in Raji is about 80%. However, analysis of the intensities of the cloned c-*myc* hybridization suggested lower RNA levels in the Raji lane previously probed with specific oligonucleotide. Normalizing the data shows ~35% untranslocated and 65% translocated c-*myc* mRNA in Raji cells. Therefore, we conclude that both c-*myc* genes are transcribed in Raji cells, unlike other examples of Burkitt's lymphoma, and this unusual transcription of the normal allele correlates with the

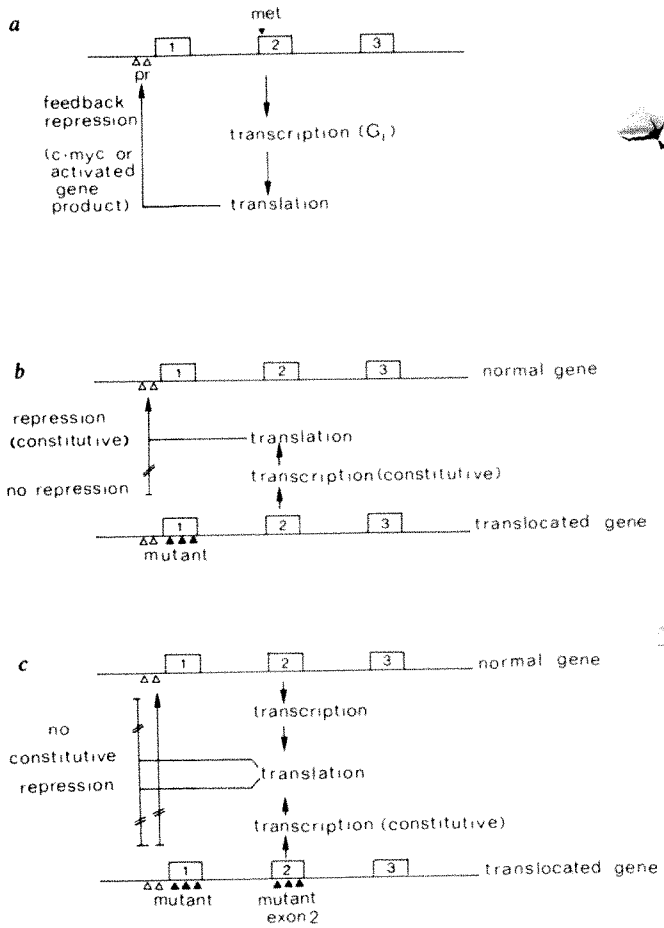

Fig. 6 Diagrammatic scheme of c-*myc* transcriptional control in normal cells (*a*) and Burkitt's lymphoma cell lines (*b*, LY67, Daudi; *c*, Raji). Note that the feedback repressor loop need not necessarily be via the c-*myc* protein itself but could occur via a gene activated by the c-*myc* protein.

presence of the codon replacements (that is, with protein alterations) in the translocated gene.

Immunological implications

In view of the data presented here, it now seems that the translocated c-*myc* very frequently suffers damage as a result of the chromosomal breakage. This is most dramatically demonstrated by studies of the gene in mouse myelomas where there is generally truncation of exon 1[1–4]; in Burkitt's lymphoma, where there is rarely loss of exon 1, there seems to be mutational damage. The difference between mouse and man in this respect is intriguing and may reflect the different rates of somatic mutation, which normally operate on the immunoglobulin variable-region genes, in these two organisms. Comparative hybridization studies of the immunoglobulin genes of mouse and man suggest that there may be as many as 10-fold more *V* genes in the former[27,28]; it was deduced from this that the comparable *V* gene variability was created by an additional mutational load imposed on the *V* genes which rearrange to give active genes in man[27,29]. The results concerning the translocation of c-*myc* support this notion and may explain why the loss of exon 1 is the more common activating event in mouse translocations. Conversely, in man mutational damage within the c-*myc* gene is the most common result, possibly because of the relatively high mutation rate in the B-cell population.

The results on the distribution of mutations and location of the BL translocated c-*myc* gene also have some implications for the mechanism of somatic mutation. Many of the translocations in man involve immunoglobulin C_H genes[11] and the breakage

occurs upstream of the c-*myc* gene (ref. 12 and see Fig. 1). Interestingly, the variant Burkitt's lymphomas break downstream of the c-*myc* gene and involve the proximity of the C_λ gene in t(8; 22)[13,15,16] or apparently the C_κ gene in t(2; 8)[30], although the break has been reported to be near a V_H gene in one case[14]. These results suggest that the common requirement for somatic mutation may be the constant-region gene, either by enzymatic recognition of this sequence as suggested previously[22] or perhaps by the particular chromatin configuration associated with the constant-region gene in these cells. In addition, it seems that the presence of an immunoglobulin constant-region gene near the translocation point is needed for the effect of the translocation to be exerted in the c-*myc* gene.

Model of c-*myc* gene activation

The data presented here show that there are substantial differences between translocated c-*myc* genes in Burkitt's lymphoma compared with normal sequences. These differences presumably arise from somatically introduced mutations associated with the DNA joining during chromosomal translocation and we would argue that the relatively restricted distribution of changes exists because such mutations provide a selective advantage (that is, growth advantage) on the affected cell. Although coding region changes do occur in Raji and LY67 (both within exon 2), as a general rule these are probably not important for oncogenesis (although they may have been in the case of Raji). More significant may be the fact that in the case of Raji, LY67 and JI, the sequence of exon 1 differs from the normal exon 1 sequence. As no coding function can be assigned to exon 1 of c-*myc*, it is possible that this segment, which is well conserved between mice and man[7,12], has a role in the control of transcription of c-*myc*[20]. Our data on the alteration of the sequence of exon 1 support this idea by providing one explanation for the activation of the c-*myc* gene in at least some Burkitt's lymphoma lines even when the chromosomal breakpoint is at some distance from c-*myc*. Similar results have recently been obtained for other Burkitt's lymphoma translocated c-*myc* genes and a similar conclusion was reached[31].

Furthermore, the results support a model in which transcription from the c-*myc* gene can be repressed by the binding of a protein to exon 1 (ref. 21), while explaining the maintenance of exon 1 with the translocated c-*myc* gene, without the requirement for elevated c-*myc* mRNA levels. Figure 6 shows this model, which incorporates our data as well as the observation that the normal c-*myc* allele is usually inactive in cells carrying translocations[12,23]. Figure 6*a* illustrates the normal transcriptional activity of the c-*myc* gene. In the resting cell, c-*myc* gene transcription is minimal but in response to stimulation (for example, mitogen[31]) transcription is initiated from promoter sites upstream of exon 1, followed by protein translation starting in exon 2. The c-*myc* protein product is then envisaged to function by activating a further set of genes (for example, those involved in DNA synthesis) which facilitate cell division. (This transcriptional role for the c-*myc* gene product seems a reasonable supposition as the protein seems to be related to the adenovirus gene E1A[32] which itself displays transcriptional control properties[33].) At the same time, repression of c-*myc* gene activity begins by protein binding (either by direct binding of the c-*myc* protein itself or by a gene product activated by the c-*myc* protein) eventually resulting in the c-*myc* gene becoming quiescent again (in a cyclic fashion). In Burkitt's lymphoma (and mouse myeloma) translocation of the c-*myc* gene seems to subtly disrupt this cyclic transcriptional control. We must also consider the possibility that disruption of control of translocated c-*myc* genes occurs via immunoglobulin locus-activating elements which exert their effects on either exon 1 or some unknown regions upstream of the c-*myc* gene. As indicated in Fig. 6*b*, Burkitt's lymphoma cells (like LY67 and Daudi described here) exhibit constitutive transcription and translation of the translocated c-*myc* gene while at the same time constitutively repressing the normal c-*myc* allele (which, of course, has a normal repressor binding facility). The cell is therefore incapable of returning to the quiescent state of c-*myc* gene activity. The case of the Burkitt's lymphoma cell line Raji is an exception: here the normal allele is not repressed, which provides direct support for the theory that the c-*myc* protein is involved in transcriptional control as we know that the Raji translocated c-*myc* gene is abnormal[22]. Therefore, we envisage that these cells express both c-*myc* alleles (Fig. 6*c*) because mutations in exon 2 of the translocated gene product inactivate or significantly reduce its repressive function. The models predicted here and elsewhere[21,31] are amenable to direct experimental testing, which is now being done using DNA transfer studies of manipulated c-*myc* genes in various types of lymphoid and non-lymphoid cell.

We thank Dr G. Lenoir for providing JI, LY91 and LY67 cells and Dr G. Klein for MAKU cells.

Observational lower mass limit for black hole formation derived from massive X-ray binaries

E. P. J. van den Heuvel & G. M. H. J. Habets

Astronomical Institute, University of Amsterdam, Roetersstraat 15, 1018WB, Amsterdam, The Netherlands

The high radial velocity amplitude (235 km s^{-1}) and 1.70-day orbital period of the B3V optical counterpart of the X-ray source LMC X-3 set a lower limit of 6–10 $M_\odot$ for the mass of the X-ray source, strongly suggesting that it is a black hole[1,2]. An observational upper limit to the mass of this compact star can be derived which, in combination with considerations about the evolutionary history of the system, allows us to derive an upper limit to the (zero age) mass of the progenitor of the compact star in this system: $\lesssim 80\pm10\ M_\odot$. From the orbital parameters of pulsating massive X-ray binaries we find that stars with masses up to $\geq 40\ (\pm5)\ M_\odot$ (and, if supernova (SN) mass ejection is symmetric, up to 60 (±7) $M_\odot$) terminate life as neutron stars. Thus, if LMC X-3 is a black hole, the lower mass limit for terminating life as a black hole is in the range between 40 (60 $M_\odot$) and 80 $M_\odot$. Together with the initial mass function of massive stars this yields a black hole formation rate in the galaxy about two orders of magnitude smaller than the neutron-star formation rate. The direct progenitors of the black holes (just before the supernova) were massive Wolf–Rayet (WR) stars.

From the optical mass function of LMC X-3 (2.3 $M_\odot$), the absence of X-ray eclipses, in combination with the observed spectral type and absolute visual magnitude of the B-type companion, Paczynski[2] derived a lower limit to the mass of the B-star of 9.0 ($\pm6.0\ M_\odot$), that is $\geq 3.0\ M_\odot$. By comparing the observed absolute magnitude of this star with theoretical evolutionary tracks, he obtained an upper mass limit of 6.6 (±2.0) $M_\odot$, that is $\leq 8.6\ M_\odot$. Thus, the allowed mass-range for the B-star is 3.0–8.6 $M_\odot$. A lower limit to the mass M_H of the compact star is set by the absence of X-ray eclipses[2] which yields $M_H \geq 6.1$ and $\geq 10.0\ M_\odot$, for $M_B = 3.0\ M_\odot$ and 8.6 $M_\odot$, respectively. Upper limits to M_H are set by the lower limit to the orbital inclination (i) derived from: (1) the observed rotational broadening of the spectral lines of the B-star, which yields $i \geq 50°$ (ref. 1), and (2) the amplitude of the photometric variability of this star which, yields $i \geq 55°$ (ref. 3). Adopting $i \geq 50°$ as a safe lower limit we obtain $M_H \leq 9.0\ M_\odot$ for $M_B = 3.0\ M_\odot$ and $M_H \leq 13.6\ M_\odot$ for $M_B = 8.6\ M_\odot$. (For the shape of the allowed domain of M_B, M_H: see ref. 1.) The above derived largest and smallest M_B, M_H combinations are listed in the first two columns of Table 1. For a certain (M_B, M_H) combination one can derive an upper limit for the mass of the progenitor of the black hole just before its core collapse, as follows. Denoting the mass of the collapsed star before the SN as M_1 and assuming an initially circular orbit and instantaneous spherically symmetric ejection (that is, in a time interval shorter than the orbital period) of the SN shell (of mass $\Delta M = M_1 - M_H$) the post-SN orbital period, semi-major axis and orbital eccentricity are given by[4]

$$P_f = (\mu_f/(2\mu_f - 1)^{3/2})P_0; \qquad a_f = a_0\mu_f/(2\mu_f - 1);$$
$$e_f = (1-\mu_f)/\mu_f \tag{1}$$

where subscripts zero and f denote the situation just before and after the SN, respectively, and $\mu_f = (M_H + M_B)/(M_1 + M_B)$ (we neglect the effects of the impact of a small fraction of the SN shell onto the B-star, as these as well as those of asymmetries are expected to be small[5,6].

As the present orbital period is only 1.70 days, tidal forces in the system are strong, and are expected to have rapidly circularized the orbit after the SN[7]. After tidal circularization the semi-major axis has decreased by a factor $(1 - e_f^2)$ (we neglect the spin angular momentum of the B-star which is several orders of magnitude smaller than the orbital angular momentum). Using this, and applying Kepler's third law one finds that the orbital period P' and separation a' after tidal circularization are related to the pre-SN values by

$$P' = P_0/\mu_f^2,\ a' = a_0/\mu_f \tag{2}$$

Because $P' = 1.70$ days, one thus can calculate P_0 for any assumed combination of M_B, M_1 and M_H. A strong constraint to the pre-SN mass M_1 of the compact star is set by the fact that, before the SN, the radius of the B-type star cannot have exceeded that of its Roche lobe, R_R, though must, on the other hand, at least have been as large as its zero age main sequence (ZAMS) value R_0.

Using the expression for the Roche lobe given by Eggleton[8], the condition that before the explosion R_0 was $\leq R_R$, in combination with the above equations yields the following condition for μ_f

$$\mu_f f^{2/3}/\{0.6f^{2/3} + \ln(1+f^{1/3})\} \geq \frac{R_0}{R_B}\left\{\frac{q^{2/3}}{0.6q^{2/3} + \ln(1+q^{1/3})}\right\} \tag{3}$$

where $f = \mu_f/(1/q - \mu_f + 1)$, $q = M_B/M_H$ is the present mass ratio of the system, and R_B is the present radius of the B-star. R_B can be simply calculated, for the given M_B, M_B combination, from the fact that the B-star fills its Roche lobe in the present orbit.

For a given (M_B, M_H) combination, q and all quantities on the right-hand side are known, such that the lower limit on μ_f can be solved. The resulting limiting values of μ_f, M_1, e and P_0 for the lower and upper limits of the range in (M_B, M_H) values are given in Table 1. For R_0 we used the values at an age of 3×10^6 yr—the approximate age at which the companion exploded—calculated by Van der Linden[10] for $X = 0.70$, $Z = 0.01$ (the approximate metal abundance of the LMC). These are

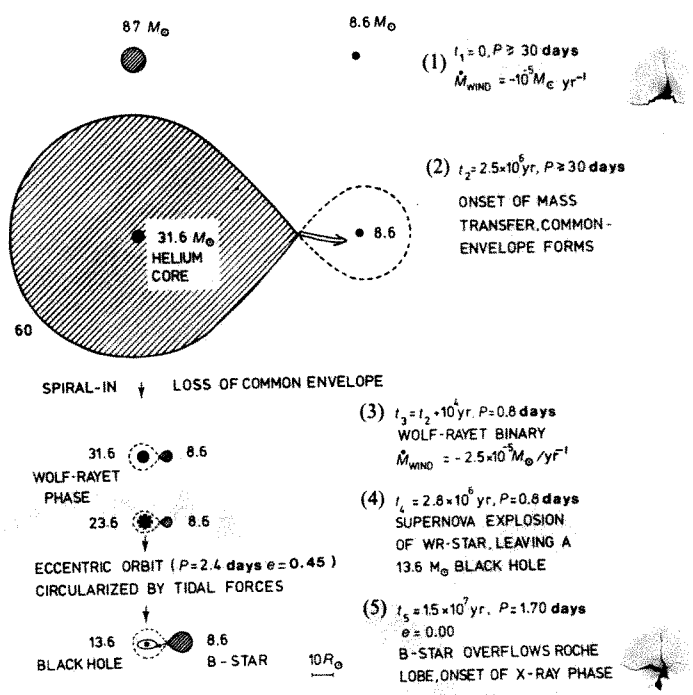

Fig. 1 Maximum-progenitor-mass evolutionary model for the origin of the LMC X-3 system, corresponding to the maximum possible masses of the compact star and its companion as allowed by the observations. Between stages (1) and (2) and between (3) and (4) the massive star undergoes stellar wind mass loss. Scale of (3), (4) and (5) is twice that of (1) and (2).

Table 1 Upper limits to the immediate pre-supernova mass M_1 of LMC X-3, and corresponding limits on μ_f, P_0, a_0, e, R_1 derived for the minimum and maximum possible values of the component masses M_B and M_H; also shown are the range of helium-core masses and initial (zero-age) primary masses M_i corresponding to the M_1 values

5.2	1.4	40	(6) Present (X-ray phase)	5.0	1.4	40

* At the onset of the (case B) mass transfer the component masses have decreased to 34 $M_\odot$ + 31.2 $M_\odot$ due to stellar wind mass loss. Some 6 $M_\odot$ is assumed to be lost during the exchange. During the $\sim 4.5 \times 10^5$ yr of helium burning and subsequent stages (between stages 3 and 4) the 15 $M_\odot$ WR star is assumed to lose 5 $M_\odot$, reducing its mass to 10 $M_\odot$ at the time of the supernova. The 44 $M_\odot$ companion needs about 1.3×10^6 yr after the mass exchange to terminate its hydrogen burning during which it loses $\sim 4 M_\odot$ by wind. This leads to the present system, consisting of a $\sim 1.4\ M_\odot$ neutron star and a 40 $M_\odot$ blue supergiant. In order to explain the observed orbital eccentricity ($e = 0.47$) the supernova mass ejection must have been very asymmetric in this model.

† Stellar wind mass loss and mass loss during the exchange was taken into account in the same way as in the other model (see text). If no mass loss occurs during the exchange, the zero age masses of the progenitor and its companion become 56 $M_\odot$ and 33 $M_\odot$, respectively.

listed in the third column. For any other (M_B, M_H) combination in the allowed range, the M_1 values are between those listed in Table 1. Notice from Table 1 that the lowest allowed value for μ_f is 0.53, which is consistent with the fact that disruption can have occurred only if $\mu_f \leqslant 0.50$ (ref. 9). The M_1 values in Table 1 are upper limits as we neglected the effects of impact, which would have further slightly enlarged e and P_f and thus would have lowered the maximum allowed M_1 values[5].

The second step is to relate these M_1 values just before the SN, to the initial (zero age) mass of the progenitor. The very short orbital period and the large mass of the pre-SN star indicate that the pre-SN star must already have been compact (see the pre-SN Roche-lobe radii R_1 of the progenitor of the compact star in Table 1): a very evolved star of $\sim 20 M_\odot$ with a radius of only $\sim 5\ R_\odot$ cannot have had any hydrogen envelope left, because such an envelope around a heavy-element core immediately expands to a large radius. Hence, the pre-SN star must have consisted of helium and heavier elements. A helium core of about 20 $M_\odot$ requires an initial stellar mass of at least about 50 $M_\odot$. Hence, the mass ratio of the initial zero age system was of the order of 0.1. In systems with initial mass ratios $\leqslant$0.3–0.4 the onset of mass transfer from the more massive (and thus more evolved) component to the less massive one leads to the formation of a common envelope in which the core of the massive star and the companion spiral in towards each other[11–13]. Figure 1 (1)–(3) depicts this type of evolution schematically. The common envelope is lost on a short time scale ($\leqslant 10^4$–10^5 yr) as a consequence of large frictional heating[13,14]. The very short present orbital period of LMC X-3 (and the even shorter pre-SN orbital period) clearly indicate that such spiral-in must have taken place here[2]. (This evolution is the high-mass analogue of the formation mechanism of cataclysmic-variable binaries, see refs 12, 13.) After the spiral-in only the compact core of the massive star consisting of helium and possibly heavier elements, remained, with an orbital period of the order of a day or less. Stripped evolved cores of massive stars are thought to be identified with WR stars[15,16]. Such stars have strong stellar winds, with mass loss rates $\dot{M} \sim (1\text{–}5) \times 10^{-5}\ M_\odot\ \mathrm{yr}^{-1}$ (refs 17, 18). During its lifetime of $\sim 3 \times 10^5$ yr (for $M_{He} \approx 25\ M_\odot$) such a star may lose some 6 $M_\odot$, so that the products of core-helium burning may become exposed at the surface, turning the star into a so-called WC star[19,20]. The progenitor of the black hole in LMC X-3 just before the SN probably was such a WC star. The presence of helium in the spectra of WC stars shows that near the end of their nuclear evolution, when their heavy-element cores occupy 75% of their initial mass[21], these stars have not yet been stripped entirely of their helium-rich outer layers. Hence, their mass at the time of the SN is $\geqslant$0.75 times the initial helium-core mass. This allows one to convert the pre-SN mass limits M_1 in Table 1 into upper limits on the helium-core mass of the progenitor. This yields the maximum M_{He} values in Table 1; the lower limits to M_{He} are equal to M_1.

In turn, these M_{He} values can be converted into initial (zero age) stellar masses, by using the relation between initial stellar mass and helium-core mass, resulting from stellar-evolution calculations in which the effects of stellar wind mass loss during core-hydrogen burning are taken into account. The calculations by Chiosi *et al.*[22] with mass loss parameter $\alpha = 0.83$, closely reproduce the observational estimates[23] of the amount of mass lost by massive stars during the core-hydrogen burning phase, and yield the relation

$$M_{He} = 0.1015\ (M_i)^{1.285} \qquad (4)$$

(for $X = 0.70$; for lower X values, M_{He} increases[24]).

This yields the maximum values for the initial mass M_i given in Table 1, in the range 69.4–86.9 $M_\odot$. Effects of convective overshooting, a smaller initial hydrogen abundance, and so on[19,20,25,26], all result in increasing the fractional mass of the helium core over that given by equation (4), and result in lower initial mass values for the progenitor of LMC X-3. We thus conclude that the upper limit to the mass of this progenitor is about 80 (± 10)$M_\odot$. Figure 1 depicts the above described

evolutionary history of the LMC X-3 system for the maximum possible progenitor mass of ~87 $M_\odot$.

An estimate of the upper mass limit for stars that terminate their evolution as neutron stars can be derived from the presence of an X-ray pulsar in the most massive known X-ray binary system 4U1223−62. The X-ray mass function of this 41.4-day orbital period system is 31 $M_\odot$ (refs 27–29). Together with the absence of X-ray eclipses—which sets an upper limit to the orbital inclination—this leads to a mass $\geq 40\ M_\odot$ for the B1.5 Ia supergiant companion[27,30]. To derive a lower limit for the mass of the progenitor of the neutron star in this system we have to consider evolution with mass exchange. To include the effects of stellar wind mass loss, we have again adopted the wind mass loss rates for hydrogen-burning O and B stars from ref. 22, as fitted by the parameter $\alpha = 0.83$. These rates are lower than given by most authors[19,20] and are therefore suitable for deriving a lower mass limit for the progenitor. As to the mass loss from the system during the exchange: a comparison between the distributions of the mass ratios of the WR-binaries and their progenitors, the O-type spectroscopic binaries, shows that at least 30% of the envelope of the primary star is lost during the exchange[32,33]. Using the condition that we wish to avoid, tandem evolution (see ref. 37), we find that the lowest-mass realistic progenitor system of 4U1223−62 has components of 42 $M_\odot$ and 38 $M_\odot$. Table 2 lists the component masses at various evolutionary stages. As we have adopted the lowest possible mass loss rates compatible with the observations (both by wind and during the exchange) it seems that 42 $M_\odot$ is about the lowest possible progenitor mass for the neutron star. If no mass loss during the exchange were adopted (but wind mass loss still is included) the smallest-mass progenitor system would be 37 + 33 $M_\odot$. Taking uncertainties in, for example, wind mass loss rates and overshooting, into account—the resulting lower limit to the mass of the progenitor of the pulsar 4U1223−62 is $40 \pm 5\ M_\odot$.

With the progenitor system of Table 2 it is impossible to explain the observed orbital eccentricity $e = 0.47$ of the 4U1223−62 system unless the supernova mass ejection was highly asymmetric. For spherically symmetric ejection the eccentricity expected from equation (1) is only 0.19. (Due to the extensive mass exchange the pre-SN orbit is expected to have been circular.) If the SN mass ejection is assumed to have been spherically symmetric, the observed eccentricity $e = 0.47$ together with equation (1) yields a mass of 22.7 $M_\odot$ for the progenitor of the neutron star at the time of the explosion. The evolutionary history of the system for this case is listed in Table 2 and the corresponding zero age mass of the progenitor seems to be about 60 (±7) $M_\odot$.

Combining the results of Tables 1 and 2 we conclude that the lower (zero age) mass limit for stars which terminate their evolution as a black hole is in the range between 40(±5) $M_\odot$ and 80 (±10) $M_\odot$. If SN mass ejection is spherically symmetric this limit is between 60 (±7) and 80 (±10) $M_\odot$. We expect these limits also to be good approximations for single stars, as single stars with masses $\geq 40\ M_\odot$ have very large rates of wind mass loss and are expected to turn into WR stars and evolve in a way similar to that of binary components[15,19,20]. Knowledge of this limit is of great importance for estimating the bulk yield of nucleosynthesis by massive stars[21].

According to Garmany *et al.*[34] the number of O and WR stars originating from stars more massive than 40 $M_\odot$, 60 $M_\odot$ and 80 $M_\odot$ within 2.5 kpc from the Sun is between 100 and 132, between 25 and 55, and between 8 and 10, respectively.

Assuming mean lifetimes of 2.5×10^6 yr, 3×10^6 yr and 3.5×10^6 yr for stars more massive than 80 $M_\odot$, 60 $M_\odot$, and 40 $M_\odot$ respectively, this yields a black hole formation rate in the solar neighbourhood in the galactic plane of $(0.2, 0.9 \text{ and } 2.0) \times 10^{-6}$ kpc^{-2} yr^{-1}, respectively. This is about two orders of magnitude smaller than the galactic SN rate[35] and the pulsar birth rate[36].

Finally, because about half of all black holes are expected to be formed in binaries, a better knowledge of the number of black hole X-ray binaries in the galaxy, in combination with the initial mass function, will allow an independent estimate of the lower mass limit for black hole formation.

Discovery of M87-like ejection in F-71

K. J. Fricke, W. Kollatschny & H.-H. Loose

Universitätssternwarte, D-3400 Göttingen, Geismarlandstrasse 11, FRG

The M87 jet[1,2] is one of the most obvious manifestations of violent activity inside the compact nuclei of galaxies whilst also being one of the most spectacular phenomena of extragalactic astronomy. Although many radio jets are known, very few optical jets have been detected and virtually none is comparable to the prototype jet in M87. Recent charge-coupled device (CCD) images of the southern object F-71 show that this elliptical galaxy ($z = 0.057$) exhibits a brilliant knot ~14 arc s away from the nucleus and is physically connected to it. Optically, this knot resembles in many respects the bright knots A and B in the M87 jet: its spectrum is featureless and very blue with a slope ($\alpha = 1.7 \pm 0.1$) equal to that of the M87 knots. Its relative luminosity with respect to, and its separation from, the nucleus are both greater than in the M87 galaxy–jet system. We suggest here that the most likely interpretation of the F-71 knot is that it is ejected from the parent galaxy in the same way as the knots in the M87 jet. We propose that further observations of the F-71 system might provide important clues to our understanding of the ejection activity from the nuclei of galaxies.

The object F-71 ($\alpha_{1950} = 20$ h 14.8 min, $\delta_{1950} = -57° 43'$) from Fairall's list[3] of compact galaxies appears as an almost circular galaxy of approximate magnitude 16 mag on the European

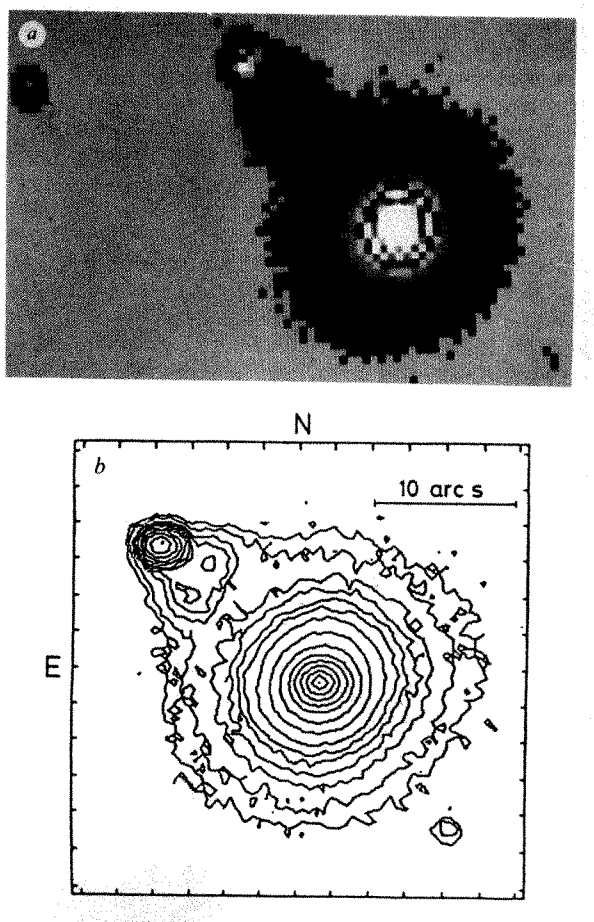

Fig. 1 *a*, CCD image in the *r*-band of F-71 showing the connection between the nucleus of the elliptical galaxy and its nonthermal knot. *b*, Contour plot of the CCD image in the *r*-band of F-71.

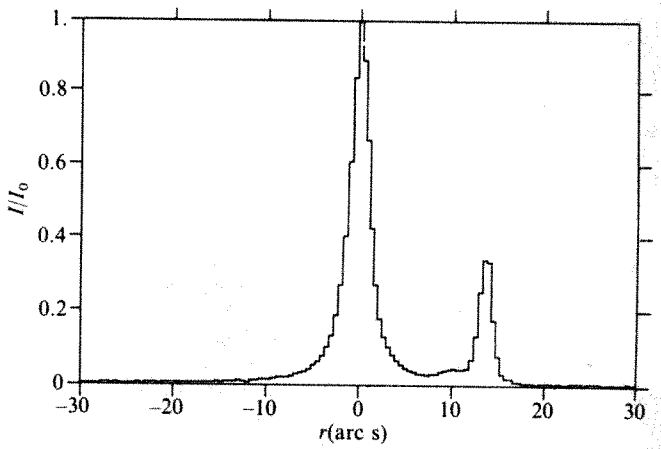

Fig. 2 Tracing through the nucleus of F-71 and the north-east knot in the *r*-band.

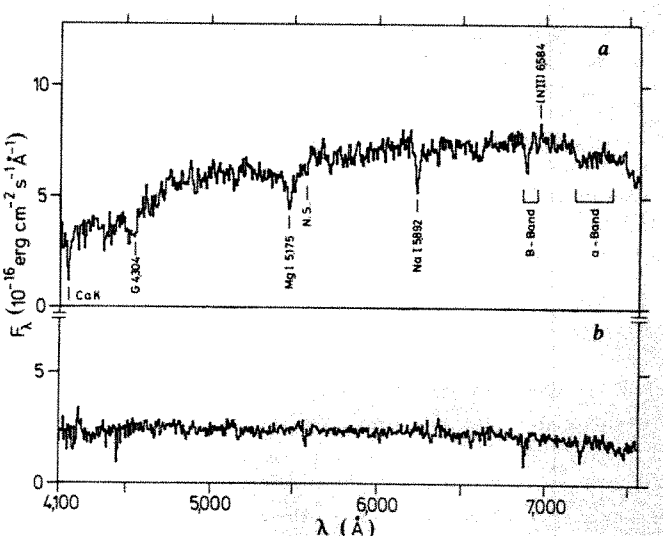

Fig. 3 The spectra of the nucleus of F-71 (*a*) and of the north-east knot (*b*).

Southern Observatory (ESO) Quick Blue Survey plate. Towards the north-east of the object a starlike companion is visible approximately 10 arc s away which has not been described before. CCD images of F-71 have been obtained on 7 and 8 May 1983 with the 1.5-m Danish telescope at La Silla (exposure time 45 min, seeing 1–2.5 arc s, 1 pixel ≙ 0.471 arc s) through various filters (*B*, *V*, *r*, *z*). All these images reveal a physical connection between the north-east knot and the parent galaxy.

As an example, we display our observational results for the *r*-band: the CCD direct image (Fig. 1*a*) shows the connection between the knot and the nucleus. The isophote representation (Fig. 1*b*) and the intensity tracing through the nucleus and the knot (Fig. 2) reveal the light distribution in more detail. The brightness distribution of the parent galaxy closely follows a de Vaucouleurs law, and is classified as an elliptical galaxy of type E0–E1. Its minor axis points in the direction of the optical north-east knot, which is located 13.75″ ± 0.3″ away from the galaxy centre in position angle (PA) 49.5° ± 0.5°. A possible weak 'counter-jet' is indicated in the direction 221.5° ± 0.5° and 12.65″ ± 0.3″ away from the galaxy centre, and shows up particularly well in the red bands *r* and *z*. The north-east knot appears slightly extended on the far side compared with stellar images on the same CCD-frames. On the near side, the optical isophotes in all filter bands show a backward extension of the compact north-east knot nearly symmetrically with respect to the line joining the nucleus and the knot (see Fig. 1 for the *r*-band). This feature is reminiscent of the "waste energy baskets" described by Longair *et al.*[4] in connection with the radio hotspots of extended radio galaxies, in particular of Cyg A. The detection of this tailed structure in all filter bands supports a physical connection between the blue knot and the galaxy as opposed to the possibility of a chance superposition of F-71 and a background object. From the tracings through the galaxy and the north-east knot we derive relative peak intensities of the knot with respect to the galaxy centre for the *z*, *r*, *V* and *B* bands, increasing towards the blue as follows: 0.31, 0.36, 0.37 and 0.53.

Optical spectra of both the galaxy and the north-east knot of F-71 were obtained on 2 September 1983 at the ESO 3.6-m telescope equipped with the Boller and Chivens spectrograph and the IDS (entrance aperture 4″ × 4″, dispersion 171 Å mm^{-1}, wavelength range 4,100–7,300 Å, exposure time 20 min each). The galaxy spectrum (Fig. 3*a*) shows absorption lines typical of elliptical galaxies. Fairall suspected, on the basis of his low-dispersion slitless spectrum of F-71, the presence of Balmer emission features. From our spectrum we cannot confirm this conjecture. Hα is coincident with the atmospheric B-band. There is marginal evidence for the presence of weak [N II] 6,584 emission. From the absorption lines we derived a redshift $z = 0.0573$ which puts F-71 at a distance 229 Mpc ($H_0 = 75$ km s^{-1} Mpc^{-1}). The visual apparent and absolute magnitudes derived from the flux at 5,500 Å are $m_V = 16.8$ mag, and $M_V = -20.0$ mag. With a scale 1.1 kpc arc s^{-1} the north-east knot is at a projected distance 15.3 kpc from the galaxy centre.

The optical spectrum of the knot appears to be featureless and flat (see Fig. 3*b*) but does not entirely rule out the possibility that the spikes in the short wavelength end of the spectrum at λ 4,216 Å and λ 4,453 Å are real and are [O II] λ 3,727 and

CaK λ 3,934 of a BL Lac object at $z = 0.13$. However, in view of the morphological evidence described above and shown in Figs 1 and 2, this interpretation does not seem to be tenable. The mean spectral index of the optical continuum of the knot is $\alpha = 1.7 \pm 0.1$ ($F_\nu \propto \nu^{-\alpha}$). The tracings through the nucleus and the knot of F-71 show that in all the colour bands the relative brightness and concentration of light between the jet and nucleus is very similar to those in M87 and its jet[1]. This may be taken as further evidence that both phenomena have the same physical origin.

F-71 and its north-east knot resemble in many respects the situation of the giant elliptical galaxy M87 with its spectacular nonthermal jet. Like M87, F-71 is an elliptical galaxy of the type E0–E1. In M87 the one-sided jet is made up of several nonthermal knots, while in F-71 a single strong knot is visible to one side and a weak feature to the opposite side. The flat and apparently lineless spectrum of the north-east knot corresponds to the nonthermal spectrum of the knots A and B of M87 displayed by Sulentic *et al.*[2]. Intriguingly, the spectral slope $\alpha = 1.7 \pm 0.1$ of the F-71 knot continuum matches exactly that of the knots A and B in the M87 jet, $\alpha = 1.7 \pm 0.2$ (ref. 5). Intrinsically, the scale of the F-71 phenomenon is an order of magnitude larger than in the M87 prototype. In F-71 the north-east knot is much more clearly separated from the main body of the galaxy than the jet in M87, and its luminosity, relative to the galaxy, is much stronger.

The optical data on F-71 described here characterize this source as a galaxy with similar ejection activity as M87, thus warranting further extensive studies, in particular in the radio region.

We thank M. P. Véron-Cetty and P. Véron for looking at the spectrum of F-71 and its knot. This work was supported in part by the Deutsche Forschungsgemeinschaft under grant Fr 325/21-1.

Conjugate ionospheric flows on Uranus

W.-H. Ip

Max-Planck-Institut für Aeronomie, D-3411 Katlenburg-Lindau 3, FRG

Consideration of the pointing direction and rotation period of the spin of Uranus suggests that a novel kind of day-to-night ionospheric flow system may exist there. For equatorial distances $r < r_c$ ($\approx 2.74 r_p$), the conjugate ionospheric flow from the dayside hemisphere to the nightside hemisphere could become supersonic as it crosses the equator and a shock forms at the termination point; for $r > r_c$, smooth transition at the contact point between the ionospheric flow from the dayside hemisphere and the nightside atmosphere is possible. The rotational effect of Uranus also limits the inner extension of the thermal plasma disk generated from energetic particle sputtering of the ring-particles and satellites. The combined effect of the dynamic transport of the ionospheric plasma and the injection of ring plasma into the upper atmosphere could provide interesting results concerning the ionosphere of Uranus, which is to be explored by the Voyager 2 spacecraft in 1986.

As a result of the slow rotation of Venus, its nightside atmosphere is not subjected to a photoionization effect; however, spaceprobes to Venus have found that it has a very dynamic and sizeable nightside ionosphere[1,2]. Its maintenance has been suggested to result from impact ionization by energetic electrons (100 eV–1 keV) accelerated in the magnetic tail[3,4], or from transport of ionospheric plasma from the dayside to the nightside[1,5]. The ionospheric transport process of Venus, driven by solar heating and solar wind interaction directly with the dayside atmosphere, is unique among the planetary ionospheres. Note that a similar day-to-night ionospheric flow pattern could also occur at Uranus because although Uranus has a rapid spin period (16.31 ± 0.27 h; see ref. 6) its rotational axis is pointing towards the Sun. This means that while one hemisphere is illuminated constantly by sunlight the other is always in darkness. Therefore, only the dayside atmosphere is affected by photoionization—just as for Venus. One major difference between Venus and Uranus, however, is that while Venus has little or no intrinsic magnetic field, Uranus should possess an intrinsic magnetic field of significant strength as recently indicated by the UV observations of enhanced H Lyα emissions at Uranus[7–9]. In fact, Hill *et al.*[10] have postulated that the equatorial surface dipole field should be ≈ 4 G.

The expected hemispherical flows in the closed field-line region are shown in Fig. 1. In the simplest situation, the photoelectron–H^+ flux streaming out of the dayside hemisphere along a flux tube will cross the equator and then be absorbed at the conjugate point.

Rösler[11] has discussed the presence of such conjugate-point ionospheric flows at the terrestrial ionosphere during solstices at high altitudes. The occurrence of this type of inter-hemispheric flow should be much more widespread at Uranus as a result of the peculiar orientation of its rotational axis at present. Following the standard treatment in solar wind theory, the hydrodynamic equations describing the ionospheric flows (assumed to be isothermal) can be combined into[12]:

$$\frac{1}{2}(M^2 - M_0^2) - \ln\left(\frac{M}{M_0}\right) - \ln\left(\frac{A}{A_0}\right) + \frac{\phi - \phi_0}{c_0^2} = 0 \qquad (1)$$

where $M = u/c$ is the ratio of the flow speed to the sound speed given as $c^2 = 2kT/m$ (kT is the plasma temperature, and m the proton mass), and A is the cross-sectional area of the flux tube. Also we have

$$\phi_g = -\frac{GM}{r} \qquad (2)$$

$$\phi_c = -\frac{\Omega^2 r^2 \cos^2\theta}{2} \qquad (3)$$

where G is the gravitational constant, M the planetary mass ($= 8.7 \times 10^{28}$ g), r the radial distance, θ the latitudinal angle, and Ω the angular rotation frequency ($\Omega = 1.07 \times 10^{-4}$ rad s^{-1}). In

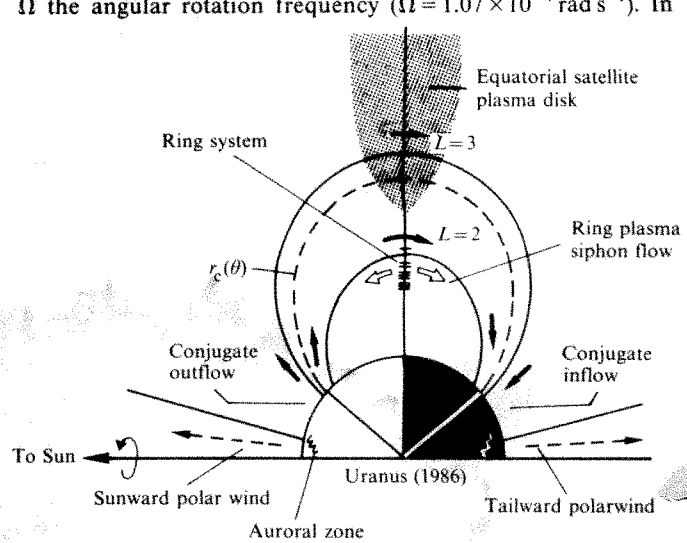

Fig. 1 The conjugate ionospheric flow pattern at Uranus. Such inter-hemispheric flows could coexist with a siphon flow of thermal plasma originates from the equatorial region as a result of energetic charged sputtering, meteoroid bombardment, and photosputtering of the rings and satellites.

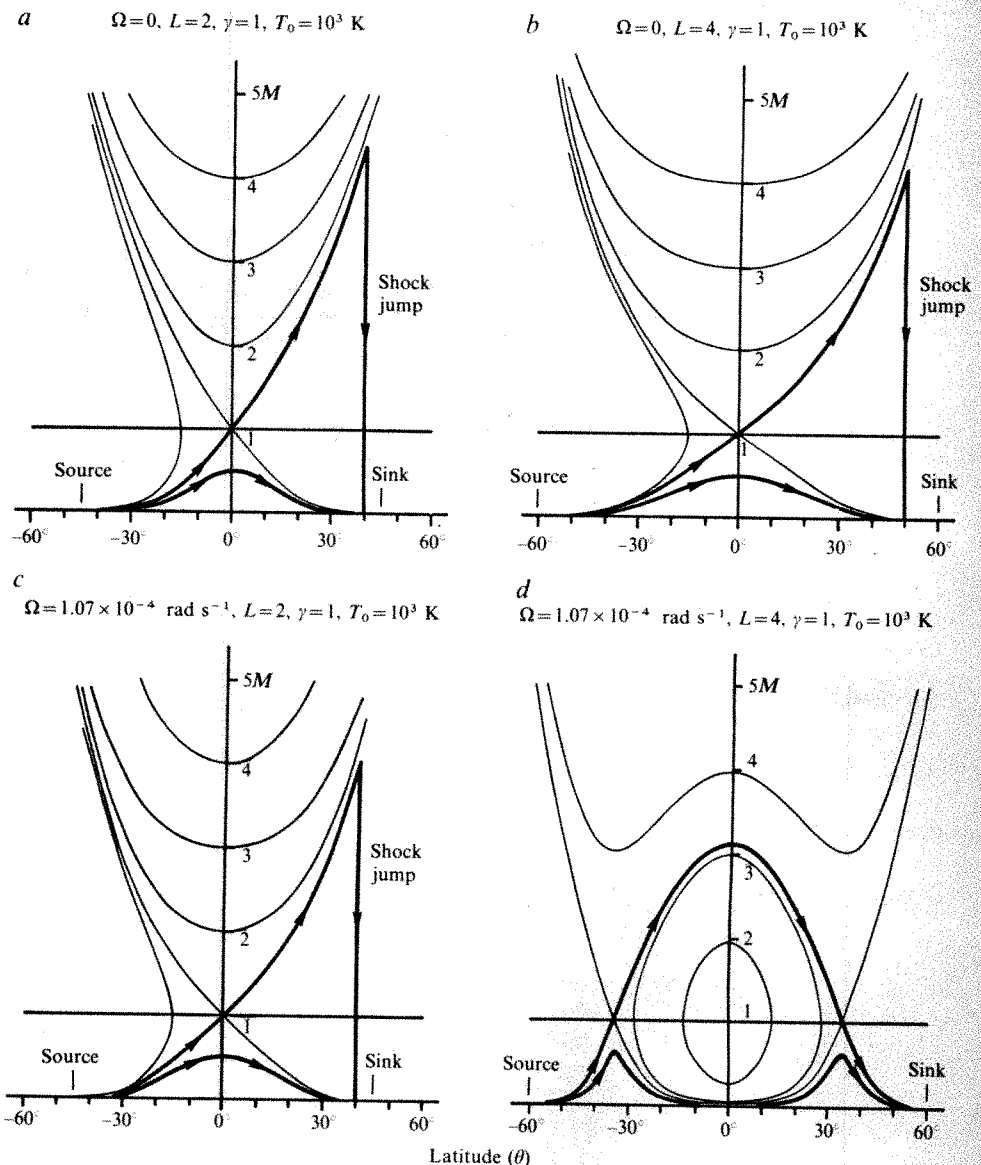

Fig. 2 Examples of isothermal conjugate ionospheric flows at Uranus with the plasma temperature set at $T = 1{,}000$ K. Four cases are considered: *a*, non-rotating case (angular frequency $(\Omega) = 0$) and the field-aligned flow crosses the equator at a radial distance of $2.0r_p$ ($L = 2.0$); *b*, $\Omega = 0$ and $L = 40$; *c*, $\Omega = 1.07 \times 10^{-4}$ rad s^{-1} (rotation period = 16.31 h) and $L = 2.0$; *d*, $\Omega = 1.07 \times 10^{-4}$ rad s^{-1} and $L = 4.0$.

equation (1) $\phi = \phi_g + \phi_c$ and the subscript (0) denotes values corresponding to radial distance r_0 and latitude θ_0 ($r = r_e \cos^2 \theta$ where r_e is the radial distance at the equator).

In the case of a non-rotating planet, several solutions to equation (1) are possible. These include: (1) transition from subsonic flow to supersonic flow before reaching the equator and then going through the reverse transition at the corresponding conjugate point; (2) reaching the sonic point at the equator and then retaining supersonic flow speed all the way to the other hemisphere; (3) retaining subsonic speed at all positions.

All of these solutions could be generated by adopting different sets of pertinent parameters (such as initial flow speed and plasma temperature) for the hydrodynamic flows. A more complete description of them will be presented elsewhere. We have depicted only a subset in Fig. 2 to demonstrate the idea of a conjugate ionospheric flow as well as the potential importance of the planetary rotation in modifying such flows. Figure 2 shows how the ionospheric flow from the dayside hemisphere might go through a sonic point as it crosses the equator or it might remain subsonic all the way to the nightside hemisphere if it starts with a smaller Mach number. In the supersonic flow case, a shock forms at the termination point as the ionospheric plasma slams into the darkside atmosphere. Such flow patterns hold for a wide range of radial distances as shown in Fig. 2*a*, *b*. However, for Uranus, there is an important modification to the flow dynamics at large radial distances; this is because the rapid rotation of the planet means that centrifugal effects begin to have a role in the force balance beyond a certain point. In the simplest possible situation, let us consider first the motion of one single charge particle. In a cold plasma approximation, neglecting the magnetic moment, the balance[13,14] between gravitational and centrifugal accelerations at the equator will define a radial distance (in the case of a perfect dipole field)

$$r_c(\theta) = \left[\frac{2GM \sec^2 \theta}{3\Omega^2}\right]^{1/3} \quad (4)$$

such that the charged particles with zero magnetic moment will be kept to the equator when $r > r_c$ but will be pulled to the topside atmosphere when $r < r_c$. Because r_c $(\theta = 0) = 6.96 \times 10^4$ km $(= 2.74r_p)$ we have $\theta_c = 53°$.

In the case of the ionospheric flow, a similar limit could apply. Figure 2 provides the most extreme examples of the modification effect by the centrifugal force on the conjugate ionospheric flow. Briefly, for flows with sonic point at the equator, those originating from latitudes $\theta < \theta_c$, the 'X-point' configuration near the equator remains unchanged. On the other hand, for those originating from latitudes $\theta > \theta_c$, the corresponding X-point configuration could be substituted by the O-point configuration such that the plasma flows should be subsonic as they reach the other hemisphere (see Fig. 2*c*, *d*). Note that the general nature of an O-type flow in a non-rotating planet remains unchanged if the rotational motion of the planet is introduced. In addition to these many possible variations in the flow patterns, the net results are that the dayside upper ionosphere should be constantly in a state of dynamic expansion instead of diffusive

equilibrium, and that the nightside atmosphere will receive a supply of ionization in this way, and a nightside ionosphere may be maintained accordingly.

In the case of Saturn, it has been postulated that the ionospheric region with magnetic field lines touching the rings should also approach the condition of free streaming—as a result of the absorption effect of the rings[15]. Because of the narrowness of the rings of Uranus, they would be less efficient in depleting the ambient plasma density in the vicinity of the ring system. The ε ring with a width of 50–100 km, however, should be able to intercept the ionospheric plasma and convert the hydrogen ions to neutralized H atoms. The ε ring should also act as an absorbing barrier in keeping the magnetospheric energetic charged particles from diffusing inward further than $2.4r_p$ (uranian radius). Cheng and Lanzerotti[16] have suggested that energetic particle sputtering of the rings could be an important cause of the thermal plasma in the magnetosphere. The associated production of the sputtered neutrals will generate a thin neutral cloud, reflecting the composition of the ring particles. The subsequent ionization of these heavy neutrals (that is, CH_4, H_2O and their fragments) will form a plasma disk at the equator. Force balance relation as considered in previous studies[14,17] indicates that the thermal plasma disk (if it exists) could be essentially limited to radial distances outside r_c. In other words, as shown in Fig. 1, a 'siphon' plasma flow from the equatorial region to the upper atmosphere should be expected in addition to the conjugate ionospheric flow. The dynamic transport of ionization from one hemisphere to another and the simultaneous loading of the atmosphere with hydrocarbons from the rings could have rather interesting effects on the ionospheric system of Uranus.

Finally, questions may be raised about how the presence of a plasma torus might affect the conjugate flow pattern. The most obvious effect is that the angular velocity of the magnetospheric plasma may be reduced to a value smaller than what is expected of rigid co-rotation, and the corresponding centrifugal force may be less important. In addition, the magnetic field configuration might be significantly changed from that of a dipole field.

Two mechanisms could be relevant here. First, as discussed previously[18] for the case of a rapidly-rotating magnetosphere[18,19], if the plasma density is large enough such that at a certain point the kinetic energy of the co-rotation motion exceeds that of the (dipolar) magnetic field energy, namely $\rho V^2/2 \geq B^2/8\pi$, no rigid rotation will be enforced; instead a radial outflow of the magnetospheric plasma stretching the magnetic field outward is expected to occur beyond this critical point. For Uranus, to reach this condition at $L \approx 4$ requires the plasma number density (assumed to be O^+ ions) to exceed $n_c \approx 10^7\ cm^{-3}$ if the equatorial surface field $B_0 \approx 4$ G, and $n_c \approx 4 \times 10^4\ cm^{-3}$ at $L \approx 8$ (the critical values of n_c are a factor of 100 smaller if $B_0 \approx 0.4$ G). But as shown by the Voyager plasma experiments[20] and theoretically demonstrated by Hill[21], in the jovian magnetosphere, non-rigid co-rotation could take place even with much less magnetospheric plasma—simply as a result of angular momentum transfer from the planetary ionosphere to the Io torus plasma. However, a large degree of non-rigid co-rotation ($\Delta\Omega/\Omega \sim 50\%$) only takes place at large distances from the source region of the thermal plasma. In the vicinity of the source region, it is the mechanism of pick-up current which has more immediate effect on the rotational rate of the local magnetospheric plasma.

Following the arguments given in refs 22–24, it can be shown that a reduction of the angular velocity of the magnetosphere will be necessitated by the acceleration of the new ions of satellite or ring origin by a pick-up current system. If the total production rate of the ions is $\dot{M}$, the radial dimension of the source region ΔR, and the integrated ionospheric Pedersen conductivity Σ_p, we have

$$\frac{\Delta\Omega}{\Omega} \approx \frac{\dot{M}L^5}{4\pi B_0^2 \Sigma_p R_0 \Delta R} \qquad (5)$$

For Jupiter, $\dot{M} \approx 1.5 \times 10^4\ kg\ s^{-1}$, $L \approx 6$, $\Delta R \approx R_0$ ($= 7 \times 10^7$ m) and $\Sigma_p \approx 0.2$ S, we have $\Delta\Omega/\Omega \approx 6\%$ which is in approximate agreement with observations[25,26]. By comparison, for Uranus with $\dot{M}$ assumed to be $\leq 10^2\ kg\ s^{-1}$, $L \approx 4$, $\Delta R \approx R_0$ ($= 2.5 \times 10^7$ m) and $\Sigma_p \approx 0.01$ S we have $\Delta\Omega/\Omega \leq 1\%$. Therefore, we expect the plasma disk of Uranus within $L \approx 5$ to be rigidly co-rotating and the magnetic field topology to be hardly affected by the mass loading effect of the pick up ions (if $\dot{M} \leq 10^2\ kg\ s^{-1}$). For larger values of L (≥ 10), it is more difficult to assess the situation as there are many uncertainties. In any case, one crucial parameter in this problem is the integrated ionospheric Pedersen conductivity Σ_p which is directly related to the whole process of transport of ionization from the dayside ionosphere to the nightside hemisphere.

Although the layer charge in 2:1 phyllosilicate minerals is known to result from the replacement of tetrahedral Si or octahedral Al, Fe and Mg by ions of lower charge, there is only limited information concerning the distribution of layer charge from X-ray crystallographic data[1–3]. Here we use ^{29}Si and ^{27}Al magic angle spinning (MAS) NMR spectroscopy to examine the site distribution of tetrahedral Si and Al in a series of synthetic trioctahedral clays with $(Si/Al)_{tetr}$ values in the range 2.74–7.69. Analysis of the ^{29}Si spectra shows that Loewenstein's rule for Al occupancy of the tetrahedral sheet is obeyed and that there is some short-range ordering for Al sites. The nature of the ordering is explained in part by the results of electrostatic potential energy calculations. In general, strong ^{27}Al resonances are observed for Al in tetrahedral sites, but the resonances due to Al in octahedral sites are considerably weaker than would be expected on the basis of chemical analysis. Consequently, no quantitative analysis of the ^{27}Al spectra is possible.

Table 1 Unit cell compositions, cation exchange capacities and X-ray diffraction data for synthetic 2:1 layered silicate clays

Compound	Unit cell composition*	$(Si/Al)_{tetr}$	CEC, mequiv. per 100 g†		d_{001} (Å)‡	
			Calculated	Observed	Air-dry	Glycerol solvated
(I)	$Na_{0.68}[Mg_{5.80}Al_{0.20}](Si_{7.08}Al_{0.92})O_{20}(OH)_4$	7.69 ± 0.23	88	91	13.1	18.0
(II)	$Na_{0.93}[Mg_{5.93}Al_{0.19}](Si_{6.64}Al_{1.36})O_{20}(OH)_4$	4.88 ± 0.08	119	134	14.2	14.6
(III)	$Na_{1.26}[Mg_{5.45}Al_{0.44}](Si_{6.51}Al_{1.49})O_{20}(OH)_4$	4.37 ± 0.12	161	170	14.0	14.5
(IV)	$Na_{1.60}[Mg_{6.17}Al_{0.08}](Si_{5.86}Al_{2.14})O_{20}(OH)_4$	2.74 ± 0.04	201	201	14.2	14.9

* The reported unit cell compositions and $(Si/Al)_{tetr}$ values are averages of five independent analytical determinations using inductively-coupled plasma emission spectroscopy. Samples were fused in lithium borate before analysis, and NBS plastic clay no. 98a was used as an analytical standard.
† Cation exchange capacities (CEC) were obtained by NH_4^+ saturated and subsequent determination of Kjeldahl nitrogen.
‡ X-ray spacings were determined for oriented film samples using Cu$K\alpha$ radiation.

Loewenstein's rule[4] states that during the isomorphous substitution of Si by Al, occupancy of adjacent tetrahedral sites by Al is avoided. An early X-ray crystallographic study[1] of Si–Al ordering in the archetypical 2:1 mica muscovite has led to a model in which the Al centres are arranged in chains, clearly violating Loewenstein's rule. More recent crystallographic studies[2,3] provide evidence for long-range ordering and separation of Al centres in the brittle mica margarite, but not in muscovite. The lack of longer-range order for muscovite does not preclude the possibility of tetrahedral Al ordering within domains, preserving Loewenstein's rule, but such short-range order is difficult to demonstrate crystallographically. Thus experiments which provide incisive information on tetrahedral site distributions are needed for the elucidation of 2:1 phyllosilicate structures.

Recent MAS–NMR studies of zeolites have shown the ^{29}Si chemical shifts to be sensitive to the number of Al ions occupying near-neighbour tetrahedral sites[5,6]. Moreover, the relative signal intensities can provide structural information which cannot be obtained by X-ray crystallography[7]. ^{27}Al MAS–NMR at high field strengths offers the possibility of providing structural information in some systems[7–9]. MAS–NMR can be equally useful for addressing the question of tetrahedral site ordering in phyllosilicates, provided that the concentration of structural paramagnetic ions is not large.

Trioctahedral clays of suitable composition and layer charge were synthesized by the hydrothermal crystallization of gels[10] at 300 °C and 100 bar over a period of 4 weeks. Table 1 provides the chemical composition and pertinent physical properties for each clay sample. Sample (I), which undergoes swelling in glycerol, may be described as a synthetic analogue of Na^+-saponite. Samples (II) and (III) carry a layer charge near the upper limit for a saponite, but they do not form a glycerol complex. Sample (IV) does not intercalate glycerol, but the layer charge is closer to the value expected for a vermiculite or mica.

Typical ^{29}Si MAS–NMR spectra are shown in Fig. 1*a* for samples (I), (III) and (IV). The relationship between the relative intensities of the ^{29}Si resonances and the $(Si/Al)_{tetr}$ values allows us to assign the lines from highest to lowest field to silicon centres in which the aluminium occupancy of the three near-neighbour tetrahedral sites is (0 Al), (1 Al) and (2 Al), respectively. None of the clays exhibits a resonance which can be attributed to Si with a near-neighbour site occupancy of (3 Al). The average chemical shifts are −95.1 ± 1.1 (0 Al), −90.1 ± 0.9 (1 Al), and −85.5 ± 0.8 p.p.m. (2 Al). It seems clear that the shifts depend mainly on the near-neighbour tetrahedral site occupancy. No second nearest-neighbour effects are observed, and there is little or no dependence of the shifts on layer charge or aluminium content of the octahedral sheet.

Representative ^{27}Al MAS–NMR spectra are illustrated in Fig. 1*b*. All of the samples exhibit an intense ^{27}Al resonance near 65 p.p.m. which is indicative of Al in a tetrahedral site[7]. Some samples (such as (IV)) also exhibit an unresolved tetrahedral Al component upfield of this resonance. Aluminium in an octahedral environment is clearly visible as a weak signal near 5 p.p.m.

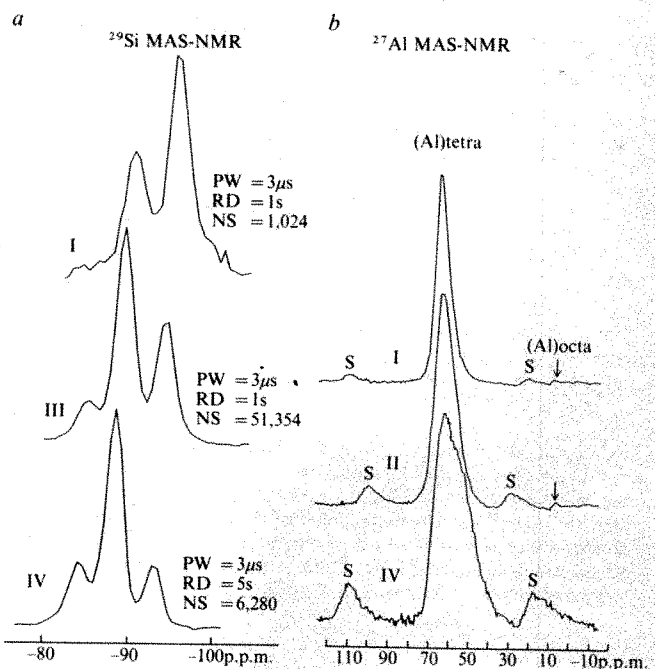

Fig. 1 *a*, ^{29}Si and *b*, ^{27}Al MAS–NMR spectra at 79.5 and 104.2 MHz, respectively, for synthetic 2:1 clays. Spinning frequencies were 4–5 kHz. Cross-polarization was not used. The pulse width (PW), relaxation delay (RD) and number of scans (NS) are provided for each ^{29}Si spectrum; the PW for a 90° flip angle was 8 μs. For the ^{27}Al spectra PW = 3 μs, RD = 40 ms, NS = 1,024. The ^{29}Si spectra were calibrated using pyrophyllite with a chemical shift of −95 p.p.m. upfield from TMS[15]. The ^{27}Al chemical shifts are relative to $Al(H_2O)_6^{3+}$. The lines labelled S are spinning sidebands.

in samples (I) and (II). However, the intensities of the octahedral Al resonances are much lower than expected from the unit cell compositions given in Table 1. Experimental pulse widths and relaxation delay times were varied over the range 3–300 μs and 0.004–2.05 s, respectively, in an unproductive attempt to improve the strength of the octahedral signal.

An analysis of the ^{29}Si MAS–NMR data, presented below, shows that our clays contain tetrahedral Al in which the near-neighbour tetrahedral sites are occupied by Si, that is, all of the tetrahedral Al is in (0 Al) environments. It is possible, therefore, that the multiple tetrahedral ^{27}Al resonances arise from differences in the occupancy of second near-neighbour tetrahedral sites. Although the octahedral Al in pyrophyllite and other 2:1 layered silicates is readily observed by ^{27}Al MAS–NMR at high magnetic field strengths, the unusually weak resonance in our samples, which are tetrahedrally charged trioctahedral structures, may be associated with a large and non-uniform electric field gradient at the octahedral sites.

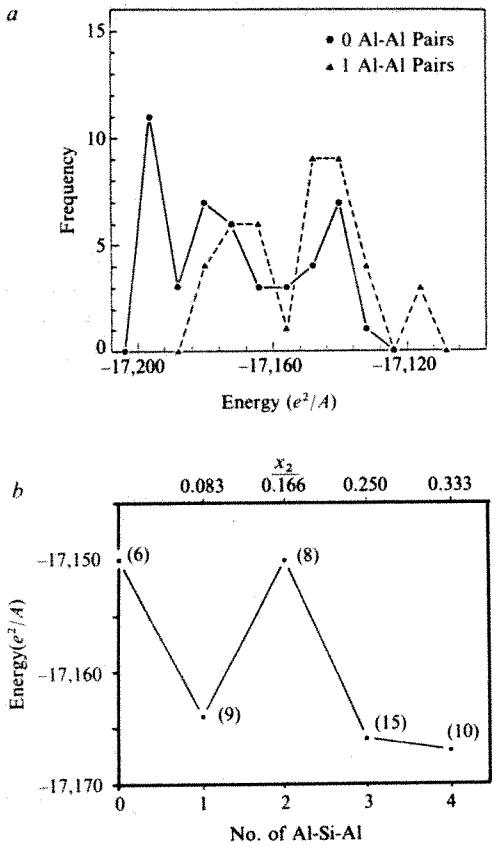

Fig. 2 *a*, The potential energy distribution obtained for 89 randomly generated mica-like structures ($x = 0.250$), grouped according to the presence of 0 (●) and 1 (▲) Al–Al linkages per unit cell [$e^2/A = 14.4$ eV]. *b*, The dependence of the average potential energies of those mica-like structures with $x_1 = 0$ on the number of Al–Si–Al linkages per unit cell. The numbers in parenthesis indicate the number of structures contributing to the average energies.

The tetrahedral site distribution in 2:1 layered silicates can be obtained from the ^{29}Si NMR intensities by an analysis similar to that made for zeolites[11]. The fraction of tetrahedral Al–Al linkages x_1, is given by $x_1 = 3x/2 - (1-x)M_1/2$, where x is the fraction of sites occupied by Al, $M_1 = (I_1 + 2I_2 + 3I_3)$, and the I_i are the normalized areas of the NMR lines due to ^{29}Si with $i = 0$, 1, 2, and 3 Al neighbours. If Loewenstein's rule holds, $x_1 = 0$, then the fraction of tetrahedral sites occupied by Al can be obtained from the NMR spectra through the expression $x = M_1/(M_1 + 3)$.

The fraction of Si sites involved in Al–Si–Al linkages, x_2, is given by the expression $x_2 = (1-x)M_2$, where $M_2 = (I_2 + 3I_3)$. For a random distribution of Si and Al in tetrahedral sites, subject to Loewenstein's rule, the probabilities of finding 0, 1, 2 or 3 Al tetrahedra adjacent to a Si can be calculated. If $(Si/Al)_{tetr} = 1/r$, the probabilities P_i, $i = 0$, 1, 2, or 3 Al, are given by the binomial distribution $P_0 = (1-r)^3$, $P_1 = 3r(1-r)^2$, $P_2 = 3r^2(1-r)$ and $P_3 = r^3$. The ^{29}Si NMR spectrum for this random distribution model consists of four lines with normalized intensities given by the P_i above.

The values of the experimental ^{29}Si-NMR line intensities and site distribution parameters defined above are given in Table 2. The values of x_1 are small and fluctuate about zero, showing that within experimental uncertainty, Loewenstein's rule is obeyed for this series of synthetic clays over the composition range $x = 0.115$–0.267. The agreement between the values of x determined by chemical analysis and by NMR analysis also is compatible with Loewenstein's rule. The experimental values of x_2 are always smaller than those predicted by the random distribution model which indicates there is some degree of short-range order in tetrahedral Al and Si sites in these structures.

Table 2 ^{29}Si MAS–NMR line intensities and tetrahedral site distribution parameters

Sample	I_0	I_1	I_2	x	x_1	x_2
(I)	0.61	0.39	—	0.115 (0.11)	0.00	0.00 (0.04)
(II)	0.52	0.44	0.04	0.170 (0.16)	0.04	0.04 (0.11)
(III)	0.35	0.55	0.10	0.186 (0.20)	−0.03	0.08 (0.12)
(IV)	0.19	0.57	0.24	0.267 (0.26)	0.02	0.18 (0.30)

The normalized integral line intensities (I_0, I_1, I_2) were obtained by fitting the observed spectra to a sum of three independent gaussian lines using a least-squares method. Values of x in parentheses were determined from the NMR line intensities, assuming Loewenstein's rule. Values of x_2 in parentheses were calculated from the random distribution model.

To understand the factors influencing the values of x_1 and x_2, particularly in the case of the mica-like sample (IV), we have carried out electrostatic potential energy calculations[12,13] on a mica structure ($x = 0.250$) with different tetrahedral Al and Si arrangements. The unit cell selected contained 16 tetrahedral sites filled by 12 Si and 4 Al. There are 1,820 different ways to fill the 16 sites. Of these, 100 were randomly selected and a crystal structure for each was derived by the DLS method[14]. Because the structural OH dipole is sensitive to cation distribution, OH was replaced by F in the model structures.

The distribution of energies for 89 of the 100 structures is shown in Fig. 2*a* where the structures are grouped according to the presence of 0 or 1 Al–Al linkages per unit cell. The remaining 11 structures, which include 2 Al–Al linkages per unit cell, have energies above $-17{,}090\ e^2/A$. There is a marked tendency for the potential energy to favour structures in which no such linkages are present (that is $x_1 = 0$). This suggests Al ions will occupy adjacent tetrahedra only rarely, in accord with Loewenstein's rule and the experimental ^{29}Si MAS–NMR results of the present work.

Figure 2*b* illustrates the dependence of the average potential energy of those structures for which $x_1 = 0$ (48 of the 89 structures) on the number of Al–Si–Al linkages per unit cell. These results show that the structures with one and four Al–Si–Al linkages (that is $x_2 = 0.083$ and 0.333) are more stable than structures containing zero and two Al–Si–Al linkages ($x_2 = 0$ and 0.166). Because of the small number of tetrahedra considered in the unit cell, the sampling of x_2 values is rather coarse. More extensive calculations with more sites per unit cell will be needed to predict accurately the most stable x_2 value.

We conclude that ^{29}Si MAS–NMR measurements on four synthetic 2:1 clays have shown that the Al tetrahedral occupancy follows Loewenstein's rule. Furthermore, by determining x_2, the number of Al–Si–Al linkages per Si, we have shown that the Al occupancy is not random, there must be short-range ordering. The calculations for a mica with $(Si/Al)_{tetr} = 3$ are consistent with this result as they show a stable configuration with an x_2 value considerably lower than that given by the random distribution model. We believe this is the first reliable demonstration of short-range ordering in 2:1 phyllosilicates.

We thank Bruker Instruments (USA) for the use of the AM-400 spectrometer and, especially, Dr Mark Matingly for assistance in obtaining spectra. M.L. thanks Dr A. J. Vega for helpful discussions concerning the ^{29}Si MAS–NMR analysis. The support of the NSF under grant CHE-8306583 (T.J.P.), EAR-780456, and EAR-8213888 (R.F.G. and P.M.C.) also is acknowledged.

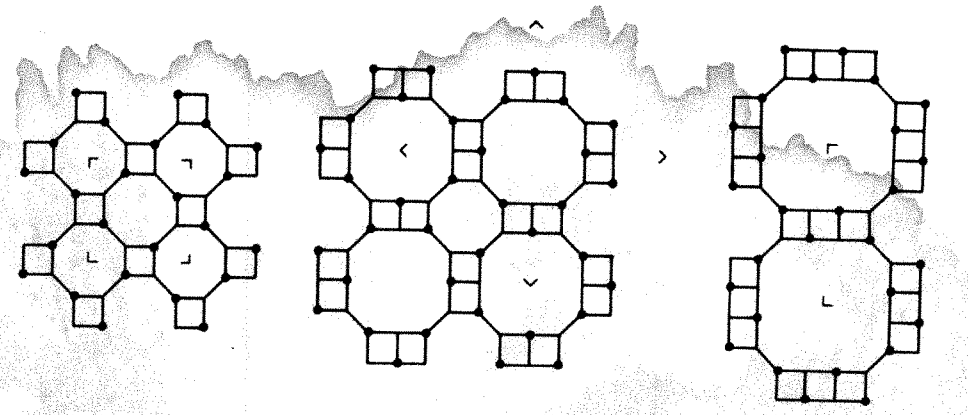
Nets with channels of unlimited diameter

J. V. Smith & W. J. Dytrych

Department of the Geophysical Sciences, University of Chicago, Chicago, Illinois 60637, USA

Three-dimensional nets and polyhedra[1,2] present an unlimited mathematical challenge, and systematic enumeration of the infinite series of four-connected nets is just developing[3–10] using selected algorithms. Several framework structures were solved and classified by invention of new nets (see refs 11–13). The four-connected nets of low density are of practical interest because their nodes may correspond with the tetrahedrally-coordinated atoms of aluminosilicate zeolites[14], some silica polymorphs[15], aluminophosphates[16,17] and other molecular sieves. The nets can be classified by circuit symbols[1–7] and coordination sequences[18,19]. Each oxygen atom of a zeolite and other tetrahedral frameworks lies near the midpoint of a branch connecting two tetrahedral nodes, and the empty volume between the close-packed oxygen atoms is important for molecular sorption. The largest ring in a natural zeolite or synthetic molecular sieve involves 12 tetrahedra[11,14], but larger rings and sphere packings of lower density are known[12,20–24]. We report here two new infinite series of four-connected three-dimensional nets which contain channels of unlimited diameter.



The four-connected three-dimensional net number 39 was obtained[4] from a stack of 4.8^2 three-connected two-dimensional nets by addition of alternating upward and downward branches. Figure 1*a* uses absence or presence of a dot at each three-connected node of the horizontal two-dimensional net to represent the colouring produced by the change of vertical direction of the fourth branch. Each single four-ring (or square) can be extended to an unlimited band of $(n+1)$ four-rings for which the simpler examples with $n = 1$ and 2 are shown in Fig. 1*b* and *c*. Correspondingly, the channel diameter in the three-dimensional net expands steadily as the limiting ring increases from eight nodes (*a*) to 12 (*b*), to (16) (*c*) and in general to $4(n+2)$. Relative rotation of adjacent bands of four-rings would allow an elliptical shape for the channels.

Similar alternation of vertical branches joining a stack of 4.6.12 three-connected two-dimensional nets[4] gave four-connected three-dimensional net number 81 (Fig. 2*a*) which is represented by the fifth member[17] of a series of aluminophosphate molecular sieves. Conversion of each four-ring into a band of four-rings produces a second infinite series for which the simpler examples with $n = 1$ and 2 are shown in Fig. 2*b* and *c*. As n increases, the limiting ring of the channel expands from 12 nodes for one four-ring to 18 ($n = 1$), to 24 ($n = 2$), and to $6(n+2)$ in general.

Strict alternation of the vertical branches is maintained in both series, and the highest symmetry is assumed for each value of n. Sub-series with lower symmetry, and with incongruent channels, can be developed by variation of n in different horizontal directions. The strict alternation of vertical branches converts each horizontal branch into a crankshaft chain[3]. Adjacent crankshaft chains around the surface of each near-cylindrical channel generate edge-shared hexagons (or six-rings) which form a 6^3 cylindrical net (stereoplot in Fig. 4 of ref. 17; CAN channel in Fig. 3 of ref. 25). Further infinite series with channels of unlimited diameter can be obtained by changing the sequence of vertical branches[4] and the type of vertical chain[5]; furthermore, complex cages are obtained by rotation of some branches as in net 83 of ref. 4. Another suite of infinite series can be obtained from the two-dimensional net (4.6.8)(4.8.12) found in mazzite and zeolite L. Full details will be published elsewhere.

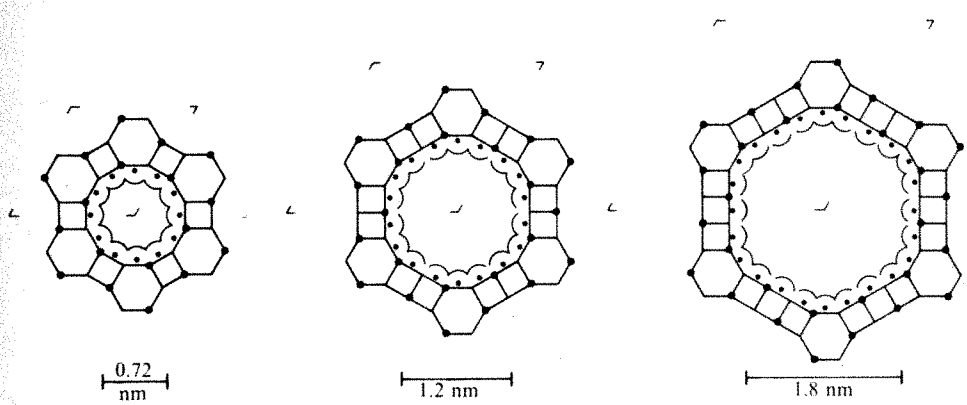
Table 1 lists the geometrical and numerical properties of the nets in Figs 1 and 2, based on the most regular geometry and an internodal distance near 0.31 nm. It is assumed that each crankshaft chain is flexed so that the repeat distance along the chain is 0.85 nm as in aluminophosphate no. 5 (ref. 17), and that the horizontal branches of the two-dimensional net are tilted. The free diameter of each near-cylindrical channel assumes that oxygen atoms (radius 0.14 nm) are placed in positions similar to those of aluminophosphate no. 5. In a real framework, for example, of Si_2O_4 composition, the geometrical details would depend on the chemical bonding, and there is some tolerance in the distances given in Table 1. For a framework of $AlPO_4$ composition with alternation of Al and P, the topochemical symmetry is lower than the topological symmetry, as in the fifth member of the $AlPO_4$ series[17].

Direct comparison with ideal sphere packings is difficult because the latter have constant distances between adjacent spheres in contrast to the considerable variation of O–O distances in the silica polymorphs and the aluminosilicate and aluminophosphate molecular sieves. Nevertheless, it is instructive to compare the density of the present series of open nets with the least dense sphere-packings in refs 20–24. First, the density of four-connected nodes decreases systematically towards zero as n increases towards infinity for each of the series based on nets 39 and 81. For T–T = 0.31 nm, the sequence of node density per nm^3 as n increases from 0 in nets 39(n) is

(*a*) 39 (*b*) 39 (1) (*c*) 39 (2)

Fig. 1 Two-dimensional projections of the first three members of an infinite series of three-dimensional nets based on strict alternation of the vertical direction (presence or absence of dot) of a fourth branch added to each node of the three-connected 4.8^2 net. Each net is shown with the most regular geometry and highest topological symmetry. The unit cell is shown by corner marks.

Table 1 Properties of three-dimensional nets in ideal expanded shape



Arbitrary no.	Z_t	Circuit symbol	Space group	Z_c	a (nm)	c (nm)	Free diameter (nm)
39	8	4.6^5	I4/mcm	16	1.0_0	0.8_5	0.3
39 (1)	24	$(4^26^4)_1(4.6^5)_2$	I4/mcm	48	1.8_7	0.8_5	0.6
39 (2)	32	$(4^26^4)_1(4.6^5)_1$	P4/mcc	32	1.6_0	0.8_5	0.9
39 (3)	40	$(4^26^4)_3(4.6^5)_2$	I4/mcm	80	2.7_1	0.8_5	1.2
39 (n)	$8(2+n)$	$(4^26^4)_n(4.6^5)_2$	*	*	*	0.8_5	$0.3(n+1)$
81	24	4.6^5	$P6_3/mcc$	24	1.37†	0.85†	0.72†
81 (1)	36	$(4^26^4)_1(4.6^5)_2$	$P6_3/mcm$	36	1.8_7	0.8_5	1.2
81 (2)	48	$(4^26^4)_1(4.6^5)_1$	$P6_3/mcc$	48	2.3_7	0.8_5	1.7
81 (n)	$12(2+n)$	$(4^26^4)_{n-2}(4.6^5)_2$	‡	$12(2+n)$	$(1.37+0.5n)$	0.8_5	$(0.72+0.5n)$

For ease of reference, each sequence of nets is given the arbitrary number of the prototype from ref. 4 plus a bracketed number for the added four-rings. All estimated distances are analogous to those observed for aluminophosphate no. 5, and a range of several percentage can be obtained by varying interatomic angles. Z_t and Z_c are the number of four-connected nodes in the unique unit and the unit cell, respectively.

* n even: P4/mcc, $8(2+n)$, $1.0+0.3n$; n odd: I4/mcm, $16(2+n)$, $1.4_{75}+0.4_{25}n$.

† Observed values for aluminophosphate no. 5. All other distances depend on assumptions about bond angles.

‡ n even: $P6_3/mcc$; n odd: $P6_3/mcm$.

(*a*) 81 (*b*) 81 (1) (*c*) 81 (2)

Fig. 2 Two-dimensional projections of the first three members of an infinite series of three-dimensional nets based on strict alternation of the vertical direction (presence or absence of large dot) of a fourth branch added to each node of the three-connected 4.6.12 net. The unit cell is shown by corner marks. Small dots show approximate positions of oxygen atoms expected for occupancy of the tetrahedral nodes by Si or by alternating Al and P, and the arcs represent an atomic radius of 0.14 nm. The approximate free diameter for a molecular sieve is shown below each net.

18.8, 16.1, 14.7, 13.0, 11.7, 10.5, 9.6.... Similarly for nets 81(n), the sequence is 17.4, 14.0, 11.6.... $16.3(2+n)/(1.37+0.5n)^2$. There is also no lower limit of density for the nets[24] constructed by the Heesch–Laves[20] procedure in which a sphere is replaced by a ring of three spheres in a sphere packing.

From the viewpoint of molecular-sieve technology, the new series of nets offer an opportunity of unlimited channel diameter if synthesis can be achieved, and the products are robust. Various large ions have proved useful as templates[26] (for example, tetrapropylammonium in the synthesis of fluoride–silicalite[27]), and further exploration of large organic species, including chains and helices, should be considered. Heteropoly and isopoly complexes of the transition metals of groups 5 and 6 (ref. 28) might also be considered if suitable conditions (including *p*H) can be found for crystallization and removal of the occluded species. The existence of large channels (1.5 nm free diameter) in the mineral cacoxenite[29] should be encouraging, even though iron (III) oxygen octahedra do not provide a suitable model for tetrahedra. The 81(n) series of nets is particularly rigid, and might prove useful in engineering design. Even if the new nets have no practical value, they extend the range of mathematical theory, and provide new opportunities for artistic development.

We thank J. M. Bennett, P. B. Moore and J. J. Pluth for discussion, N. Weber for technical help, and NSF for financial support (CHE 80-23444; DMR 82-16892).

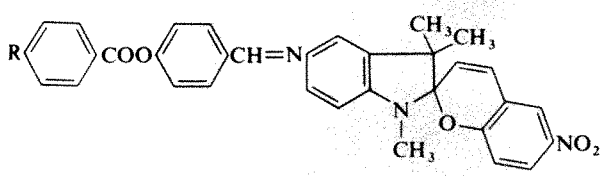
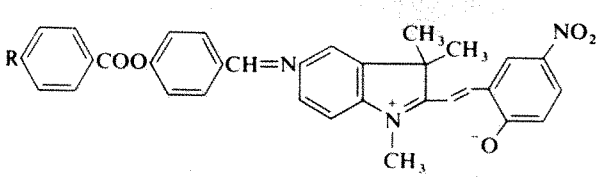
Quasi-liquid crystals



Felix Shvartsman & Valeri Krongauz

Department of Structural Chemistry, The Weizmann Institute of Science, Rehovot 76100, Israel

Photo- and thermochromic conversion of spiropyrans into merocyanines[1] is used to 'engineer' new types of molecular organizates[2–6], based on the capability of the merocyanine dyes to give giant molecular stacks[7]. One type of spiropyran–merocyanine organizate, the so-called quasi-crystal, is formed when the photochromic reaction occurs in an electrostatic field. The quasi-crystals are composed of assemblies of dipolar molecular stacks covered by amorphous materials and aligned along the field[2,3].



Quasi-crystals exhibit optical nonlinearity[4]. Other types of organizates occur in macromolecules bearing spiropyran side groups[5,6]. Both inter- and intramolecular stacking of merocyanine side groups have been disclosed. Here we describe a new spiropyran–merocyanine organizate obtained in spiropyrans containing mesogenic groups. These materials exhibit some features of liquid crystals (birefringence, orientation in an electric field), but have structures that are completely different from conventional liquid crystals. We propose that organic compounds with this novel form of organization be called quasi-liquid crystals (QLCs).

Spiropyrans of the general formula *A* (R = CH_3O—, *n*—$C_6H_{13}O$—, CN—, see below) were synthesized by a process that will be described elsewhere. The structures and purities (> 99%) of the spiropyrans were established by chemical analysis, NMR and mass-spectroscopy. The colour changes of these materials are associated with the following reversible reaction[1]:

A (spiropyran)

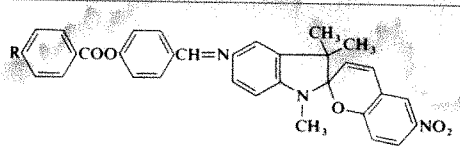
$h\nu, \Delta \rightleftarrows h\nu, \Delta$ (1)

B (merocyanine)

Crystals of these spiropyrans, obtained by slow crystallization from a suitable solvent, have sharp melting points (Table 1) and give isotropic melts.

The compounds can also be obtained as thin amorphous films by fast evaporation of the solvent from their solutions on a glass surface. In this way we prepared very viscous (grease-like) transparent films of ~0.5 μm thickness. They are metastable and remain in the amorphous state for between several hours and several days, depending on their thickness, temperature of preparation and the substituent R. The amorphous films obtained from mixtures of spiropyrans proved to be much more stable. We ascribe the formation of the amorphous films to the presence, at low concentrations, of merocyanine molecules. This merocyanine apparently acts as an impurity, retarding crystallization of the films.

Heating the amorphous films induces a change to an anisotropic structure, observable in the polarization microscope through its strong birefringent texture (Fig. 1*a*). The appearance of this texture coincides with a substantial change in the film colour, from pale yellow to bright green or greenish-blue. The change in colour is associated with a shift of the thermal equilibrium (1) to the right, with increasing temperatures. At a still higher temperature this texture disappears: above this clearing point total extinction of light is observed through cross polarizers. The temperature range in which the textured structure exists is much lower than the metling point (m.p.) of the crystals (Table 1). For example, for the spiropyran with R = CH_3O— the m.p. is 198–203 °C, while the temperature range for the birefringent texture is 50–130 °C. The material above 130 °C is an isotropic liquid; below the melting point of the crystal it is metastable. The texture disappears above 130 °C, and reappears on cooling below 130 °C. However, this process is not completely reversible due to the competitive crystallization process, which is slow at low temperatures but faster at higher temperatures. The beginning of this crystallization process is shown in Fig. 1*b*. The clusters of non-birefringent dark spots are microcrystals.



Films cooled to room temperature retain their anisotropic structure. It looks as if the mesophase is 'hidden' beneath the crystal phase and appears only when we destroy the crystal lattice by dissolving the crystalline spiropyrans. However, this is not the case, because the isotropic material obtained by heating spiropyran crystals above the melting point gives, on cooling, isotropic glass, which does not exhibit birefringence on being reheated from room temperature, that is the system does not exhibit properties of monotropic mesophases.

For orientation in an electric field a thin amorphous film was cast onto a glass slide with interdigital electrodes. The QLC were orientated in a constant electric field of $>0.5\ kV\ mm^{-1}$. For example, films of spiropyran with R = CH_3O— give at 90 °C and $E = 1.5\ kV\ mm^{-1}$ nearly homogeneous birefringence (Fig. 2). The higher the field and the temperature (below the clearing point) the better and more uniform was the orientation determined from the linear dichroism. Very thin films (<1 μm) are oriented much more slowly and less completely, probably due to an anchoring effect. Orientation in the field was also observed on the hydrophobic surface obtained by treating the glass with a solution of octadecyltrichlorosilane in bicyclohexyl.

The most remarkable effect of the electrostatic field is the stabilization of the quasi-liquid crystalline state which accompanies the orientation of the films. Spontaneous crystallization no longer occurs. In the supercooled conditions at room temperature the orientation and glass-like state were preserved without change for at least 3 months after the field was switched off. Both electron microscope results (to be published) and optical microscope observations showed the absence of crystals. However, at temperatures above the clearing point the electric field does not cause orientation but on recooling in the field the orientation is restored.

Stabilization of the oriented supercooled films allowed us to measure the absorption spectra of the QLC with polarized light (Fig. 3). The extinction coefficients of the spiropyrans (ε_{sp}) were measured in solution in benzene (Fig. 3). They are, at 370 nm, 2.23×10^4 and 1.75×10^4 for the compounds with R = CH_3O— and R = CN—, respectively. The extinction coefficients at the visible absorption maxima (ε_{mer}) of the merocyanines obtained from different spiropyrans lie in the rather narrow range $(3–5) \times 10^4\ l\ mol^{-1}\ cm^{-1}$ (refs 1, 2). Assuming these coefficients to be valid for the films we can estimate the ratio of the concentrations (C) of merocyanine and spiropyran in these films from the abosrption spectra: $C_{mer}/C_{sp} = (\varepsilon_{sp}/\varepsilon_{mer})\ (D_{mer}/D_{sp})$, where D_{mer} and D_{sp} are the absorptions of merocyanine and spiropyran, respectively. It is estimated that the extent of conversion of spiropyran into merocyanine on heating for different films is only 3–10%. A further, most surprising, fact is that the absorption spectra of the films are dichroic only in the region of the merocyanine absorption band ($\lambda_{max} \sim 600$ nm), while in the region of spiropyran absorption ($\lambda_{max} \sim 370$ nm) the degree of linear dichroism is vanishingly small. This means that only the merocyanine molecules are oriented in the electric field,

Table 1 Characteristics of spiropyrans

I R = CH_3O
II R = *n*—$C_6H_{13}O$—
III R = CN—

Compound and mixture	Melting point* (°C)	Temperature ranges of phases (°C) Amorphic → QLC	QLC → Isotropic

II	165–168	45	110
III	210–214	80	170
I : II = 3 : 1	—	50	135
I : III = 1 : 1	—	60	140

* Not corrected.

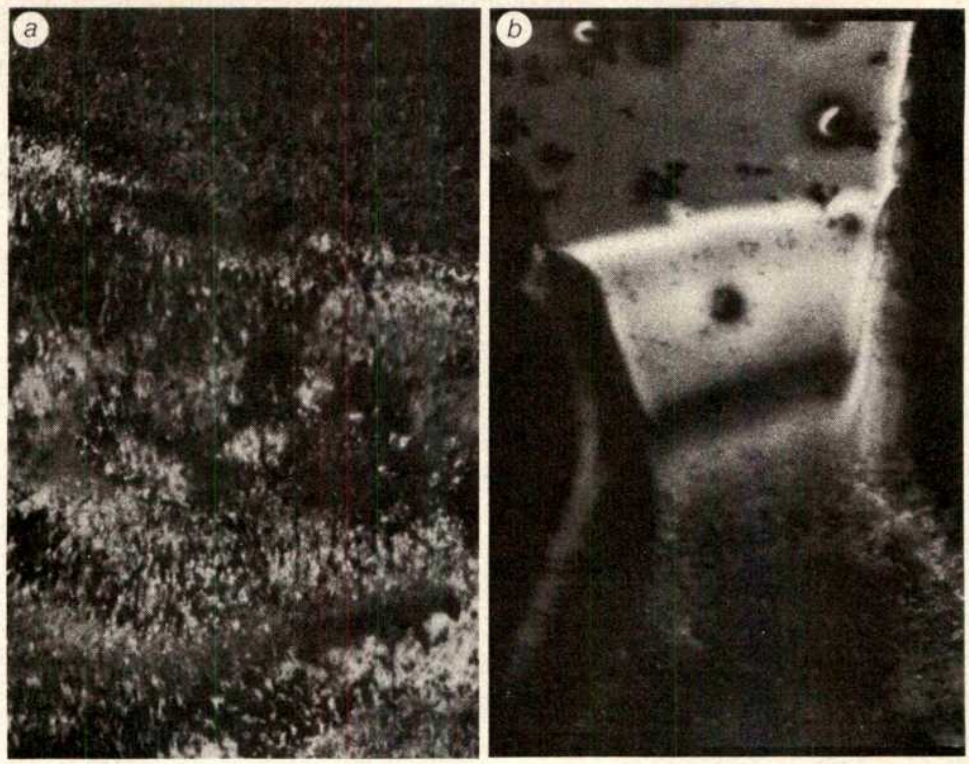

Fig. 1 Optical texture of unaligned QLC films viewed through crossed polarizers. *a*, Mixture of spiropyrans with R = CH_3O— and CN—, in the ratio 1:2, at 115 °C. *b*, Spiropyran with R = CH_3O—, at 90 °C; clusters of non-birefringent microcrystals are distinctly seen on the yellow and bluish-grey sections as shown on the front cover of this issue.

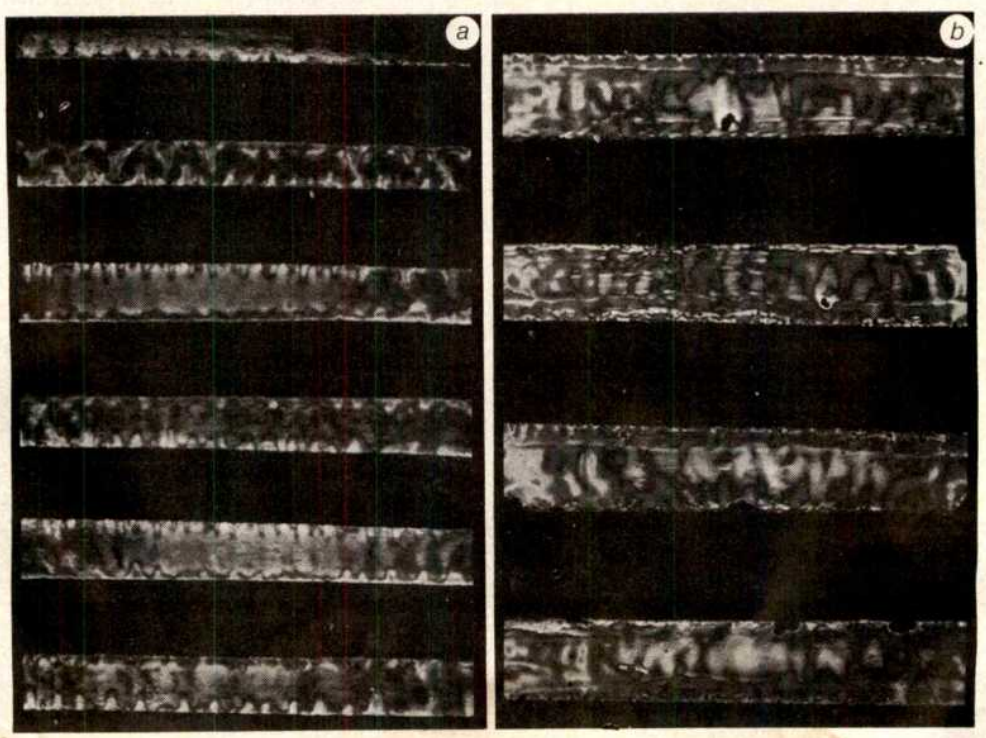

Fig. 2 Optical texture of QLC films aligned in an electrostatic field ($E = 1.5$ kV mm^{-1}, at 90 °C, distance between electrodes = 1 mm), viewed through crossed polarizers. The dark parallel stripes on the picture are areas of the interdigital electrodes. *a*, Mixture of spiropyrans with R = CH_3O— and CN—, in the ratio 1:2. *b*, Spiropyran with R = CH_3O—.

while the bulk of the material, which consists of spiropyran molecules, is unoriented.

The order parameter of the merocyanines is given by $S = (D_\parallel - D_\perp)/(2D_\perp + D_\parallel)$, where $D_\parallel$ and $D_\perp$ are, respectively, the absorptions parallel and perpendicular to the electric field. This parameter depends on the field strength, the temperature and the film thickness. For example, a 1:2 mixture of spiropyrans with R = CH_3O— and CN— gives $S \simeq 0.2$ at 90 °C and $E = 1.5$ kv mm^{-1}. The direction of the long molecular axis, coincident with the direction of maximum absorption of polarized light, is parallel to the field for all examined compounds and mixtures.

Orientation of the films in a low-frequency alternating field (~ 50 Hz) was also observed, but in this case the oriented QLC were not stable and crystallization occurred very rapidly.

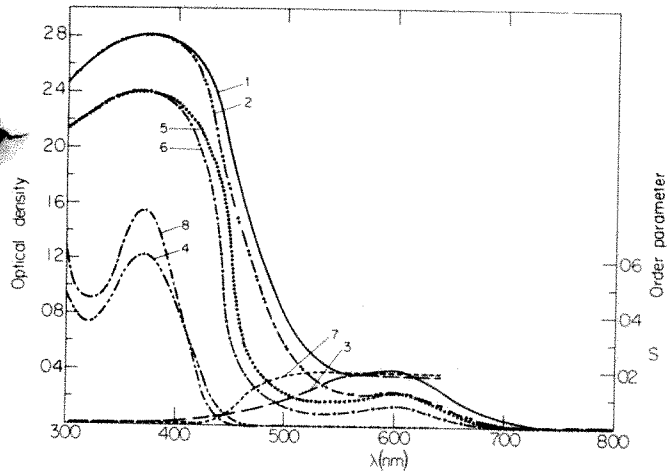

Fig. 3 1–4, Spiropryan with R = CN—: 1,2-absorption spectra of oriented QLC films, light polarized respectively parallel and perpendicular to the electric field; 3, order parameter, *S*, as a function of λ; 4, absorption spectrum in benzene solution. 5–8, As 1–4, but for spiropyran with R = CH_3O—.

Simple considerations, similar to those given in refs 2 and 3, lead us to conclude that orientation of separate merocyanine molecules is inconceivable in an electric field as weak as 1–1.5 kV mm^{-1}. Only assemblies of interacting molecules, having large net dipole moments, can be oriented in such a field. It is also inconceivable that the weak interactions, associated with the anisotropy of the polarizabilities of the mesogenic groups, and responsible for the occurrence of the liquid crystalline state of material, would keep together the merocyanine molecules in such assemblies. Indeed, the concentration of merocyanines in the isotropic spiropyran bulk is low (3–10%) and the existence of liquid crystalline domains of merocyanines in a predominantly isotropic phase is thermodynamically highly improbable.

Apparently the merocyanine molecules with the mesogenic groups somehow impose mesophase features on the bulk material: very intensive birefringence in the liquid phase, which indicates ordering of the material and characteristic temperature behaviour. These properties are not inherent in the spiropyran-merocyanines organizates that we studied previously. It is improbable that in the QLC the merocyanines or their complexes are organized in molecular stacks similar to those in quasi-crystals or in 'zipper' polymer crystals because the viscosity of the material is extremely high and stack formation by diffusion would be extremely slow. Rather, the interaction of the dipolar merocyanine molecules with the surrounding spiropyrans results in formation of small domains similar to solvating shells or to the asymmetric micelles in lyotropic systems[8]. If these domains interact with one other they may provide the material with QLC properties. On raising the temperature above the clearing point the ordering of the domains is presumably destroyed. The fact that QLCs appear only in the films cast from solution and never from spiropyran melt may indicate some kind of latent preorganization or complexation developing on evaporation of solvent.

We thank Professors M. D. Cohen and E. Fischer for reading the manuscript and valuable comments, and Mrs A. Yacov and Mr I. Cabrera for assistance.

Sapropelic deposits in a sediment from the Guinea Basin, South Atlantic

R. J. Morris, M. J. McCartney & P. P. E. Weaver

Institute of Oceanographic Sciences, Brook Road, Wormley, Godalming, Surrey GU8 5UB, UK

Until recently it has been generally thought that a stagnant water column is a prerequisite to the formation of organic-rich deposits in deep-water marine sediments, a belief best exemplified by studies on the eastern Mediterranean sapropels. Many workers have assumed that, following the hydrological isolation of the deep waters, stagnation of the eastern Mediterranean basins and the concomitant development of anoxic conditions occurred before the deposition of the sapropelic layers[1–10]. Opposing arguments suggesting a role for increased marine productivity have, however, been put forward, both specifically with respect to the eastern Mediterranean sapropels[11,12] and more generally regarding deep-water organic-rich deposits[13–15]. We report here the discovery of sapropelic layers (>0.5% organic carbon)[16] in a recent sediment core from a deep-water site in the Guinea Basin. It is thought most unlikely that stagnant conditions could prevail in the water column at this site, and preliminary analyses of the sediments suggest that the organic-rich deposits have been a direct result of increased productivity in the overlying water column, the most recent occurring about 18,000 yr ago and coinciding with the last glacial maximum.

The core (10529) was collected using a Kastenlot corer[17] equipped with a 4-m long 15 × 15 cm section barrel during RRS *Discovery* 128 cruise to the South Atlantic. The core site was on the flat abyssal plain of the Guinea Basin (4°56.8′ S 0°27.7′ E, water depth 4,735 m). The sediment core consisted of alternating marls and oozes. The oozes were grey to black in colour and distinct black-grey bands were found in each of the ooze deposits (Fig. 1).

A microscopic analysis indicated large numbers of Radiolaria and large amounts of siliceous (mainly diatom) debris in the oozes. There appeared to have been a considerable variation in the degree of carbonate dissolution throughout the core but no obvious relationship between dissolution and either the marl or ooze deposits, although particularly strong dissolution was seen at the base of the lowest ooze deposit (350 cm).

The results of a stratigraphical analysis based on coccolith distributions is shown in Fig. 2. Relative percentages of *Emiliania huxleyi* and *Gephyrocapsa* spp. have been used to determine ages. The reversal in dominance between *G. oceanica* and *E. huxleyi* is known to occur, in tropical areas, at about 85,000 yr whilst the first occurrence of *E. huxleyi* is dated at 270,000 yr (ref. 18). The peak abundance of *G. aperta* between these two dates has been recorded by Breheret[19] and Weaver[20] and it occurs in oxygen isotope stage 7. No evidence of any major sediment reworking, such as by turbidites, was found. Any such sediments would contain mixed young and old coccolith assemblages which were not present in the samples analysed in this work. The fact that the distributions closely match those found in other studies[18,20] suggests that the core is stratigraphically intact with an average sedimentation rate of 1.4 cm kyr^{-1}.

Organic carbon, carbonate and X-ray diffraction analyses[21] show the oozes to have considerably raised levels of organic carbon (Fig. 1) and opaline silica (Fig. 3*a*), but much reduced amounts of calcium carbonate. The calcium carbonate values were confirmed by X-ray emission analysis[11] for CaO (Fig. 1). The three major ooze deposite coincide with peaks in the organic carbon values with a double peak in the most recent ooze. The low carbonate values in the oozes could be caused either by dissolution or dilution of the carbonate fraction. Visually there appeared to be no consistent relationship between dissolution of carbonate tests and the ooze deposits. Furthermore plotting the organic carbon and opal values on a carbonate-free basis

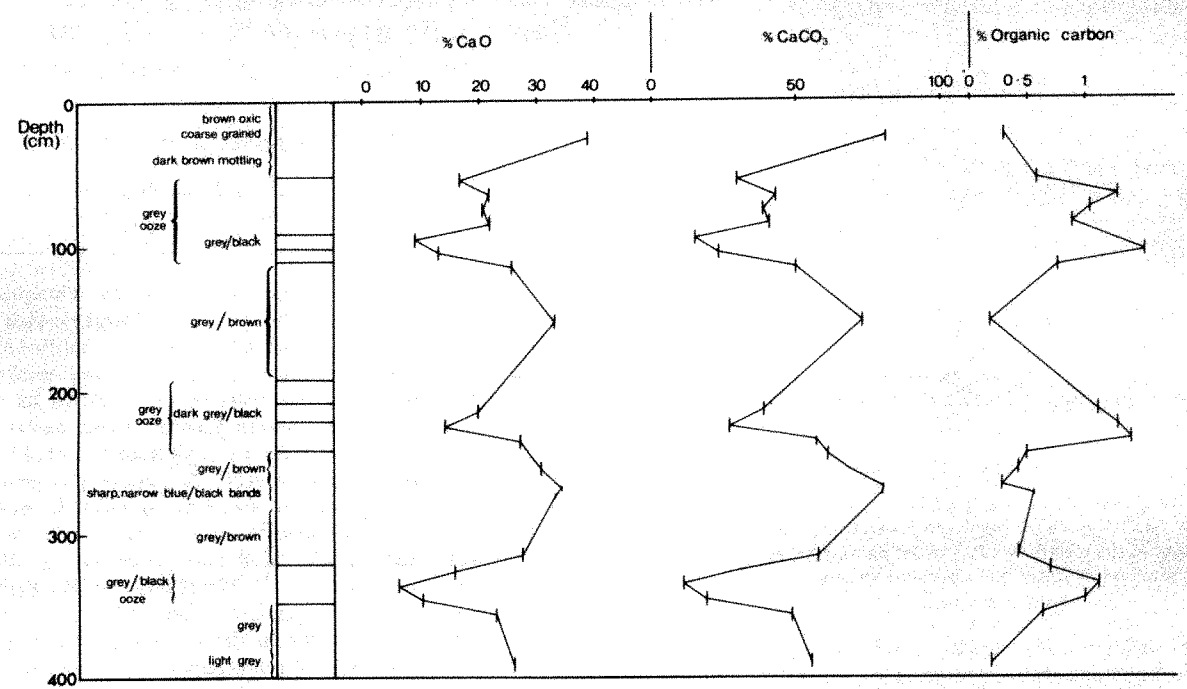

Fig. 1 Core description and content of organic carbon carbonate (% dry weight of sediment).

(Fig. 3*b*) indicates that the variation in these components are independent of variations in the carbonate content. The available evidence suggests that the increased levels in organic carbon and opaline silica reflect periods of increased inputs of biogenic silica to the sediments diluting the normal carbonate contribution.

Quartz levels in the core are generally low (<1%) but X-ray emission spectrometric analyses[11,12] indicate that there have been increased contributions of fine-grained alumino-silicate minerals to the sediment during ooze deposition (Fig. 3*a*). The origins of these inputs are at present unknown, but again there is no evidence of major post-depositional sediment transport (such as turbidites) in the core.

Some 10-cm horizons from the upper part of the core were taken for ^{14}C dating and $\delta^{13}C$ measurements (Table 1). Age data based on carbonate ^{14}C give no indications of any major contribution by turbidites in the upper 90 cm of the core, in agreement with the stratigraphical analysis (below 90 cm the age of the core is beyond the ^{14}C dating method). The ^{14}C carbonate ages give accumulation rates of between 0.8 and 3.4 cm kyr^{-1}.

Sufficient organic carbon was present in the 60–70 cm and 70–80 cm depth horizons for the determination of the component ^{14}C organic ages (Table 1). The most recent organic carbon enrichment (60–70 cm) coincides with the last (Stage 2) glacial maximum, taken here to be 14,000–19,000 yr BP. The determined organic carbon ages are considerably younger than the corresponding ^{14}C carbonate ages. This effect, though not normally to this extent, has been frequently noted[22] and has been attributed to the reworking of old carbonate particles into contemporaneous sediment[11]. In the present work, the coarseness of the sample horizon is thought to be another factor. The determined ages are an average of a 10-cm band, yet within these horizons a range of sedimentation could have occurred with the relatively steady carbonate sedimentation being periodically supplemented by shorter episodes of organic sedimentation. Turbidites are not thought to be an explanation for the discrepancy between the ^{14}C carbonate ages and ^{14}C organic ages; any turbidite action would have caused anomalies in both sets of age determinations.

The $\delta^{13}C$ measurements suggest that the organic material in the 60–70 cm and 70–80 cm horizons is derived overwhelmingly from marine planktonic sources[11,20]. This is further evidence against turbidite action; the continental shelves and slopes around the Niger delta are the most likely sources for turbidites

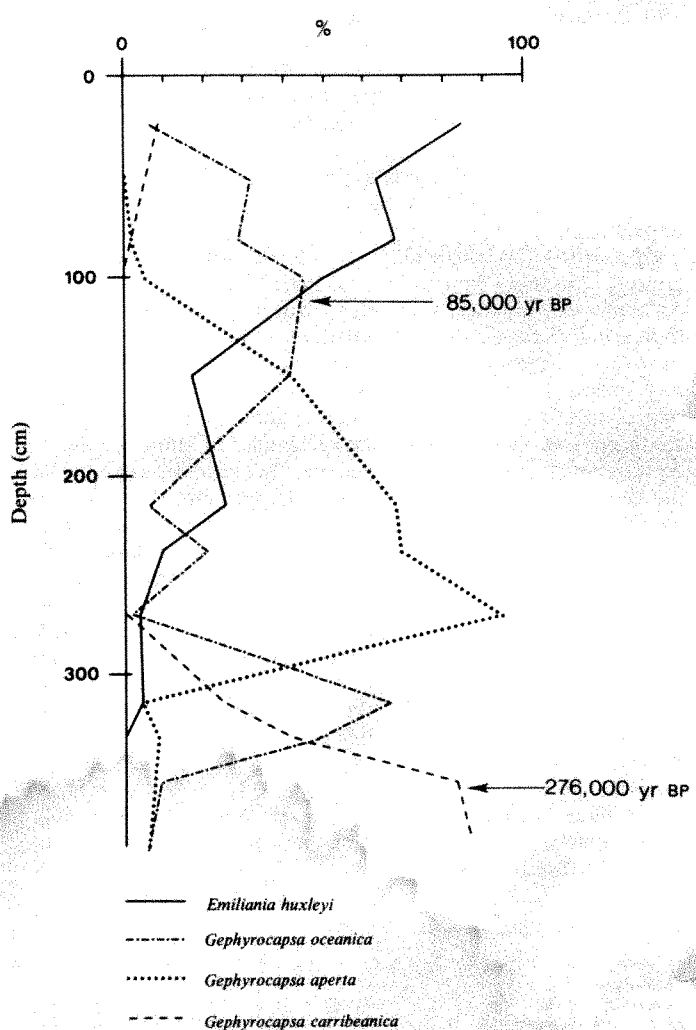

Fig. 2 Coccolith stratigraphy. The distributions suggest continuous deposition to beyond 276,000 yr. The two dates in the right hand column are derived from ref. 17.

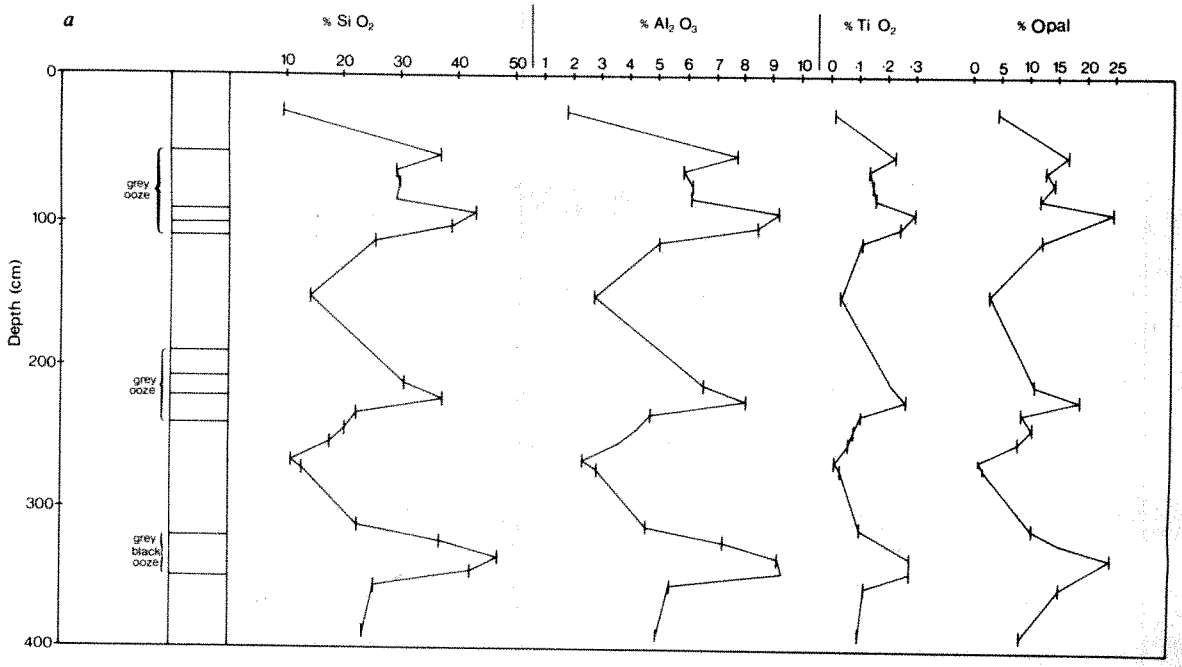

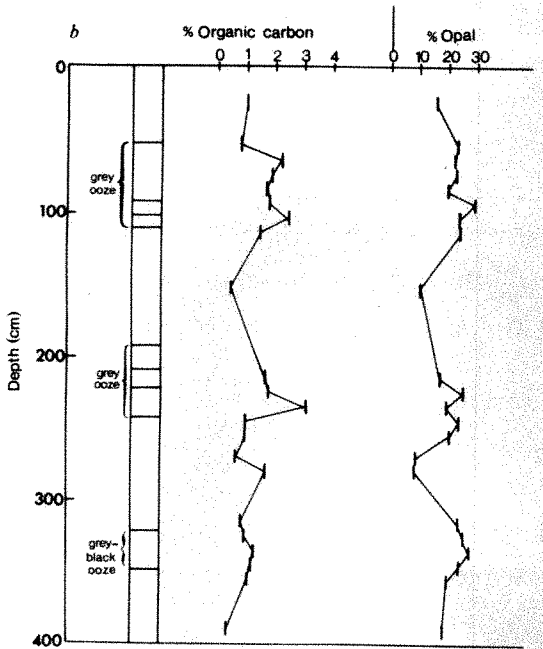

Fig. 3 *a*, Basic mineralogical composition (% dry weight of sediment). *b*, Organic carbon and opaline silica data expressed on a carbonate-free basis.

in this area and such sedimentary sites would be expected to receive a considerable contribution of organic matter from terrigenous sources resulting in greatly more negative $\delta^{13}C$ values.

Preliminary analyses on the component lipids from the dark band within the most recent ooze (97–102 cm) show a fatty acid profile dominated by C_{14}–C_{18} even chain acids (>85% total fatty acids). Long chain fatty acids (C_{26}–C_{30}), which are typical organic components of most terrigenous inputs, were only minor components (<6% total fatty acids). Such a fatty acid profile is taken to indicate that marine phytoplankton dominated the organic input during this period of the core's history with a minimal input of terrigenous organic material[23,24]. There was a considerable monounsaturated fatty acid component (11–12% total fatty acids) which is somewhat surprising for a sediment sample at least 30–40,000 yr old. We believe that for such good preservation of labile, unsaturated lipid the original organic source material must have been deposited rapidly in a relatively intact state.

Studies on some of the organic-rich oozes which underlie the present day highly productive areas of the ocean (the upwelling areas off Namibia and Peru) have indicated that in the relatively shallow continental shelf and slope areas the organic material in the sediments originates mainly from the rapid sedimentation of phytoplankton *blooms*[21,23–28]. It has been suggested that the sedimentation occurs in a series of discrete 'events', giving large pulses of biological material which sink rapidly blanketing the underlying sediment surface[25] and ensuring the burial of large quantities of the organic debris. In such conditions two processes occur which are thought to aid the preservation of the sedimented organic material. First, an increased flux of organic compounds to a sediment–water interface stimulates microbial activity with a concomitant development of anoxic conditions in the interfacial sediments. Thence bacterial degradation will be limited to all but the anaerobic species and auto-oxidative breakdown will be much reduced. Second, high molecular weight humic compounds are rapidly formed from the natural product organic molecules present in phytoplankton detrital material[26,29,30]. These high molecular weight moieties will be more resistant to chemical and biological attack than the initial natural product molecules.

Work on phytoplankton blooms occurring in experimental enclosed ecosystems has largely supported these hypotheses[29,30]. However, they only relate to geochemical processes which are

thought to occur in marine water columns of, at most, a few hundred metres.

The development of stagnant hydrographical conditions have normally been invoked as the primary process[1–10,31] for the preservation of organic material in sediments underlying water columns of several thousands of metres depth. However, peaks in the organic carbon profiles of recent deep-water sediments (2,700–3,500 m) from the eastern equatorial Pacific[15] has been taken as evidence for periods of significantly increased productivity in the area during the last glacial maximum. The sediment under present study is from a considerably deeper core site (4,735 m) in the middle of a flat abyssal plain interrupted only by a few isolated sea mounts. It is very difficult to imagine that stagnant conditions have prevailed in the overlying water columns at this site during the history of the core (~300,000 yr). Whilst conclusive evidence is not available to prove this point, there is strong evidence to support the hypothesis that the deep-water, organic-rich ooze deposits found in this core from the Guinea Basin were a direct result of periods of increased productivity in the surface layers of the overlying oceanic water column. First, the core mineralogy shows that the ooze deposits were associated with a considerable increase in the input of biogenic silica. Second, the most recent peak in organic carbon corresponds to a period of raised sedimentation. Third, the stratigraphical analysis, ^{14}C carbonate age profile, $^{13}\delta C$ measurements, quartz data and fatty acid analyses all show no major turbidite influence in the core. Fourth, the $^{13}\delta C$ and fatty acid data indicate that the organic matter in the most recent ooze deposits mostly originated in marine plankton.

The recent report of a seasonal pulse of organic detrital material to bathyal and abyssal depths being derived directly from the surface primary production[32] supports this theory.

We thank Dr D. D. Harkness of the Scottish Research Reactor Centre for providing $\delta^{13}C$ data and ^{14}C dates.

Isotope studies of insular phosphates explain atoll phosphatization

Paul Aharon

Carbonate apatite[1] with the general formula $Ca_{10}(PO_4, CO_3)_6(F, OH)_2$ is a major component of the phosphate deposits that occur on numerous coral reef islands[2–6]. Such insular pohsphates are generally accepted to be the result of chemical interaction between solutions leaching seabird guano and the underlying reef limestone[2,7]. Details of this process, however, and the specific environmental conditions which promote it, are not yet fully understood[8]. We present here oxygen and carbon isotope data from carbonate apatites which elucidate the process of phosphogenesis on the Pacific atolls and the palaeoclimatic conditions in which it occurs. We suggest that there were drier climates in the tropics during the Quaternary ice ages associated with an extension of equatorial upwelling in the Pacific.

In the expectation that the oxygen and carbon isotopic composition of CO_2 sources of structural carbonate in apatite may leave a characteristic fingerprint of the depositional environment[9,10], we have initiated an exploratory study of oxygen and carbon isotope abundances of insular phosphates from coral reef islands in the tropical Pacific (Fig. 1). Samples from Ebon Island (4°35′ N, 168°43′ E) and Nauru (0°25′ S, 166°57′ E) (see Table 1) were chosen as representative of minor phosphate rock deposits on low-lying atolls and major deposits on high islands respectively. Two samples from Ocean Island (0°53′ S, 169°35′ E) and Makatea (15°50′ S, 148°13′ W) are also included to augment the representation of high oceanic islands capped by phosphates and separated by wide stretches of ocean (Table 1, Fig. 1). The phosphate from Ebon Island is typical of atoll phosphate rock, or "crust guano"[2,11]. The material consists of coral rubble, mainly coral aragonite, bound together with thinly laminated collophane (cryptocrystalline apatite) cement, thought to be a primary precipitate which forms when phosphatic solutions leached from guano first come into contact with the limestone substrate. Minor aragonite micritic cement coexists with the apatite in the fine laminae. The phosphates from the high-lying atolls are of two distinct types (see Table 1). The first are typical of the unconsolidated phosphate ore *filling* the depressions between pinnacles (karst remnants). These samples are fine to medium-size pisolitic and oolitic pellets with a markedly concretionary structure and are thought to be formed by rapid interaction of the solutions leached from the guano with the directly underlying coral-sand[7]. The second are phosphatized reef rocks *in situ*, including: (1) pure apatite cast of reef-coral where the coral carbonate skeleton has been completely removed by subsequent dissolution; (2) banded phosphate layers overlying pinnacles; (3) translucent (agate-like) phosphate called nauruite[2] occurring in depressions and cracks of the pinnacles. Materials produced from the capping of phosphate on Ocean Island, similar to the two types above, are termed by Owen[7] as incoherent and coherent phosphates respectively. We also took samples from the black phosphatic soil which covers the phosphate ore on Nauru with a thin layer. To place constraints on the timing of the apatite emplacement in the respective deposits, U-series age estimates have been used[12].

Experimental procedures were similar to those described by Kolodny and Kaplan[9], but were designed to permit separate analysis of CO_2 derived from the apatite and associated components, that is carbonate and organic matter. Accordingly, any carbonate coexisting with the apatite was selectively removed in dilute acetic acid[13]. The remaining apatite, verified by X-ray

diffraction measurements to be free of any associated carbonate, was then dissolved at 25 °C in 100% H_3PO_4 for 72 h. The isotopic fractionation of oxygen in the evolved CO_2 was assumed to be the same as calcite[9]. The organic matter residue was filtered on silicon paper and combusted at 900 °C in pre-evacuated quartz tubes in the presence of CuO and silver wire[14]. The aragonite cement from the Ebon phosphate was chipped off under a microscope and analysed separately. The CO_2 evolved from the separate fractions was analysed in a gas-source mass spectrometer for $^{18}O/^{16}O$ and/or $^{13}C/^{12}C$ isotope ratios following standard procedures[15]. The results reported according to the conventional 'δ' notation are shown in Table 1. The $\delta^{18}O$ and the $\delta^{13}C$ values from Table 1 are plotted in Fig. 2 together with those from known or likely sources for the apatite-CO_2.

These data can be interpreted as follows: The $\delta^{18}O$ value of −1.5‰ for the apatite–CO_2 of Ebon Island phosphate closely approximates the $\delta^{18}O$ value of −1.6‰ in the coexisting aragonite cement and is compatible with a CO_2 source in isotopic equilibrium with seawater[16–18]. The difference of $\delta^{13}C$ observed between the aragonite and the apatite–CO_2 (2.5‰ and 0.7‰ respectively, Table 1, Fig. 2) implies that ~8% of the CO_2 could be attributed to contamination of the inorganic carbon pool by aerobic degradation products of guano. This interpretation is supported by the $\delta^{13}C$ of the organic matter associated with the apatite (−23.5‰, Table 1) which is near that of modern guano ($\delta^{13}C = -19.5$‰) from Heron Island—a typical lagoonal platform near the southern end of the Great Barrier Reef.

Although neither Ebon nor Nauru presently support seabird colonies, the high contents (up to 9%, Table 1) of organic matter associated with the apatite from Ebon is consistent with our interpretation of a guano source, as no other mechanism would introduce such high carbon contents. The carbon-isotopic composition and the high concentration of the phosphate organic fraction thus provide direct evidence for seabird guano as the most likely and direct precursor of insular phosphates in accordance with Hutchinson's proposals[2,19].

Involvement of seawater during apatite formation on Ebon Island, implied by the oxygen isotope data, is independently supported by the relatively high fluorine content of the apatite fraction, because neither guano nor reef limestone are adequate sources for this element[12]. In fact, the wide range of fluorine content exhibited by different insular phosphates[2] has been attributed to variable exposure of insular apatites to sea spray or seawash[20] which in the case of low island deposits is not difficult to envisage.

By contrast, the distinctly light $\delta^{18}O$ and $\delta^{13}C$ yielded by the phosphates from Nauru (Table 1) may indicate apatite deposition from meteoric waters presumably following emergence of Nauru more than 200,000 yr ago. This suggestion is supported by (1) the proximity of the $\delta^{18}O$ and $\delta^{13}C$ values to the field of coral-reef limestones recrystallized in subaerial environments on Pacific islands (Fig. 2); (2) petrographic evidence which indicates that some of the coherent apatites formed as casts that preserve coral textures and that subsequently the coral dissolved presumably on subaerial exposure; and (3) geological evidence[2] which indicates that phosphatization of the atoll evidently occurred when Nauru was even more elevated than it is today. The isotopic compositions of the apatites from Ocean Island and Makatea, which are within the range of values reported for the apatites from Nauru, suggest a strong similarity between the depositional environments of these phosphate deposits. Two additional points require further discussion.

First, the extreme light $\delta^{13}C$ compositions of the apatite–CO_2 from Nauru, averaging −12‰, is consistent with a source of carbon in the meteoric water formed by roughly equal amounts of CO_2 generated by guano aerobic decay ($\delta^{13}C = -19.5$‰) and dissolution of a reef limestone substrate of $\delta^{13}C = -4.5$‰ (ref. 21). Variability in the observed $\delta^{13}C$ compositions of the apatites could reflect either departure from a ratio of 1 between the two CO_2 endmember sources and/or limestone substrates of variable $\delta^{13}C$ compositions (Fig. 2).

Fig. 1 Distribution of guano phosphate deposits in the South Pacific Region and pertinent ocean chemistry and biology data (after ref. 32).

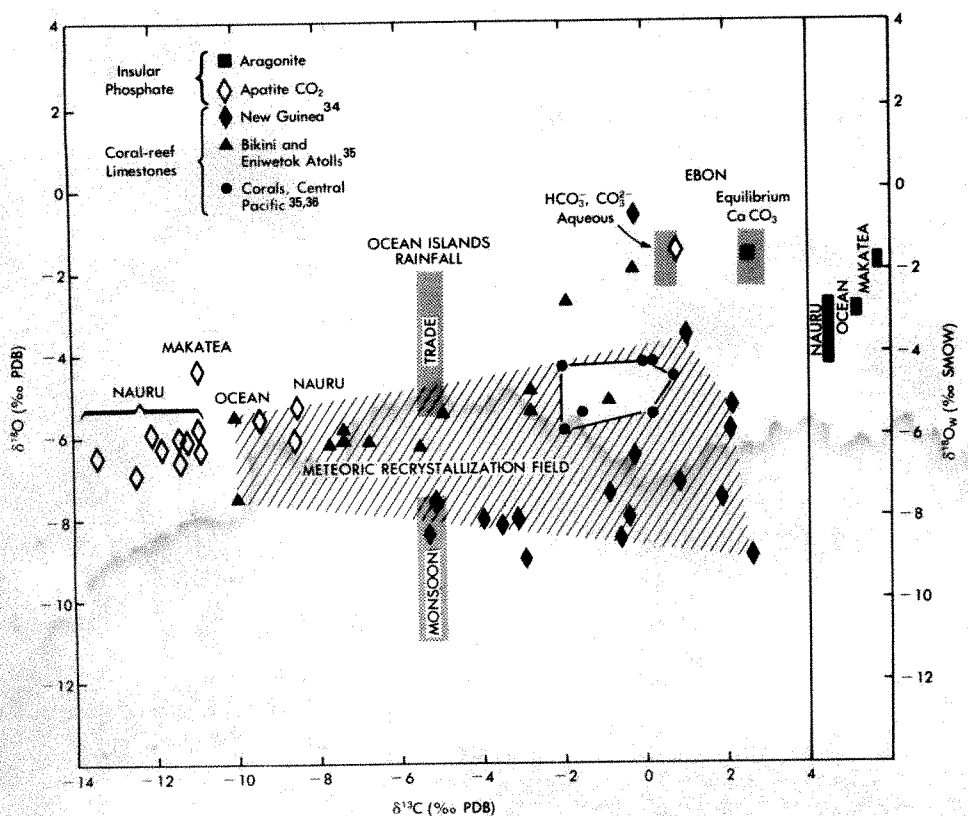

Fig. 2 $\delta^{18}O$ and $\delta^{13}C$ values of phosphatic material from low and high islands (Ebon and Nauru, Ocean Island, Makatea respectively) and the isotopic ranges of possible inorganic CO_2 sources. On the right column are the estimated $\delta^{18}O$ ranges of the palaeowaters from which the respective phosphates were deposited. Note that carbonate and phosphate $\delta^{18}O$ values are reported relative to the PDB standard while water is relative to SMOW standard. The relationship between the two reference standards is given by the expression[33]: $\delta^{18}O_{PDB} = 0.97\delta^{18}O_{SMOW} - 29.94$.

Second, groundwater which is abundant during subaerial diagenesis is a large reservoir and buffers the $\delta^{18}O$ of chemical precipitates in the vadose zone[21,22]. With one qualification to be discussed below, the narrow $\delta^{18}O$ range yielded by the subaerial phosphates reported here probably reflects the narrow $\delta^{18}O$ range of local rainfall during diagenesis[22]. In this context, the ^{18}O-enrichment of 2.5‰ observed in the apatite from Makatea relative to the apatites from Nauru (Fig. 2) is consistent with the documented $\delta^{18}O$ differences between the western and eastern tropical Pacific rainfalls[23].

If the apatite–CO_2 formed in isotopic equilibrium with the meteoric water, then the oxygen isotope composition of the phosphatizing solutions can be estimated using an ambient temperature of 28 °C, the present mean monsoonal temperature on tropical Pacific islands, and the calcite geothermometer[24]. The latter has been shown to be indistinguishable from the apatite–CO_2 geothermometer[25]. Viewed this way, $\delta^{18}O$ values of the phosphatizing solutions range between −4.3 to −2.7‰ SMOW on Nauru and Ocean Island and −1.8‰ SMOW on Makatea (Fig. 2).

Studies have shown that $\delta^{18}O$ values of groundwater reflect the isotopic composition of precipitation during the season of maximum infiltration[26]. Thus abundant monsoonal rainfalls, unusually depleted in ^{18}O relative to the trade precipitation (Fig. 2), must provide the main source of meteoric water at tropical Pacific sites affected by the monsoonal circulation[27,28]. For example, the ^{18}O-depleted meteoric water is well imprinted in the $\delta^{18}O$ compositions of late Pleistocene coral-reef limestones from New Guinea shown in Fig. 2. As isotopic modelling[29] indicates that Nauru and Ocean Island presently pertain to the same province of light $\delta^{18}O$ rainfall as New Guinea ($\delta^{18}O = -6$ to −8‰ SMOW), this reasoning would suggest that phosphates on these islands were formed from meteoric waters with ^{18}O contents appreciably different from present precipitation in the region. The apparent ^{18}O-enrichment may be attributed to the effect of monsoon failure, increased evaporation, or both, and in either case mean that major phosphate deposits of Pleistocene or earlier ages on high islands were formed in much drier climatic conditions than those now prevailing.

According to Hutchinson[2,19], the distribution pattern of islands with modern guano deposits suggests that organic productivity caused by upwelling, coupled with low rainfall, favour the net accumulation of guano and hence should provide an adequate source of phosphorus for the formation of insular phosphate deposits (Fig. 1). However, the distribution pattern of ancient insular phosphate is quite different from that of modern guano deposits and cannot readily be explained in terms of present climatic conditions.

The results of this study tentatively support Hutchinson's explanations of these differences, namely that they are related to shifts in frequency and abundance of tropical rainfall during the ice ages—factors which also affect the temporal and spatial distribution of guano phosphate deposits. Our suggestion of drier climates in the tropics during the Quaternary ice ages is quite consistent with an intensified Hadley circulation[30] and a strong development and extension of equatorial upwelling in the Pacific[31].

This study was initiated during a Queen's Fellowship tenure at the Australian National University and completed at LSU (P.A.). H.H.V. was supported by the Australian Research Grants Scheme. We thank Dr J. M. McArthur for constructive criticism and Dr D. Z. Piper from USGS for sharing with us samples from Nauru.

An extraordinary peat-forming community on the Falkland Islands

R. I. Lewis Smith

British Antarctic Survey, Natural Environment Research Council, Madingley Road, Cambridge CB3 0ET, UK

R. S. Clymo

School of Biological Sciences, Queen Mary College, London E1 4NS, UK

Most of Beauchêne Island in the South Atlantic is covered by tussac, the tussock-forming grass *Poa flabellata* (Lam.) Rasp., which has produced a deep accumulation of exceptionally dense peat during ~ 12,500 yr. The basal peat is lignitic, yet it is several hundred times too young to be a true *lignite*. During an ecological survey of the island in December 1980[1], one of us (R.I.L.S.) sampled an 11-m high peat face. The age against depth profile in the peat is consistent with a constant proportional rate of decay of $1.1–2.2 \times 10^{-4}$ yr^{-1} and a constant rate of addition of dry matter to the peat of 430–720 g m^{-2} yr^{-1}. This rate of decay is within the range recorded for peats in corresponding latitudes in the Northern Hemisphere, but the rate of addition of dry matter is about 10 times as great. This is not easy to accommodate within current hypotheses about peat formation. An unusual combination of biological, physical and chemical circumstances may be the cause. As the island is difficult to visit and no more information can be obtained in the near future, we now report these results, incomplete though they are.

Beauchêne Island[1,2] (lat. 52°54′ S, long. 59°04′ W) is the most southerly and isolated of the Falkland Islands in the South Atlantic Ocean. It is ~187 hectares in area, rises to 82 m altitude and is 60% covered by continuous closed tussac grassland. Individual plants, at a density of 600–700 per hectare, reach 3.5 m in height, including a peaty pedestal 1.0–1.5 m tall, and 2 m in diameter, and have a canopy up to 4.5 m across; a skirt of dead foliage extends from the side of the pedestal and interlaces with the skirts of adjacent plants. This is an almost truly monospecific plant community with almost no ground flora.

A further 35 hectares are occupied by dense mixed colonies of about 300,000 pairs of rockhopper penguins (*Eudyptes chrysocome*) and 160,000 pairs of black-browed albatrosses (*Diomedea melanophrys*).

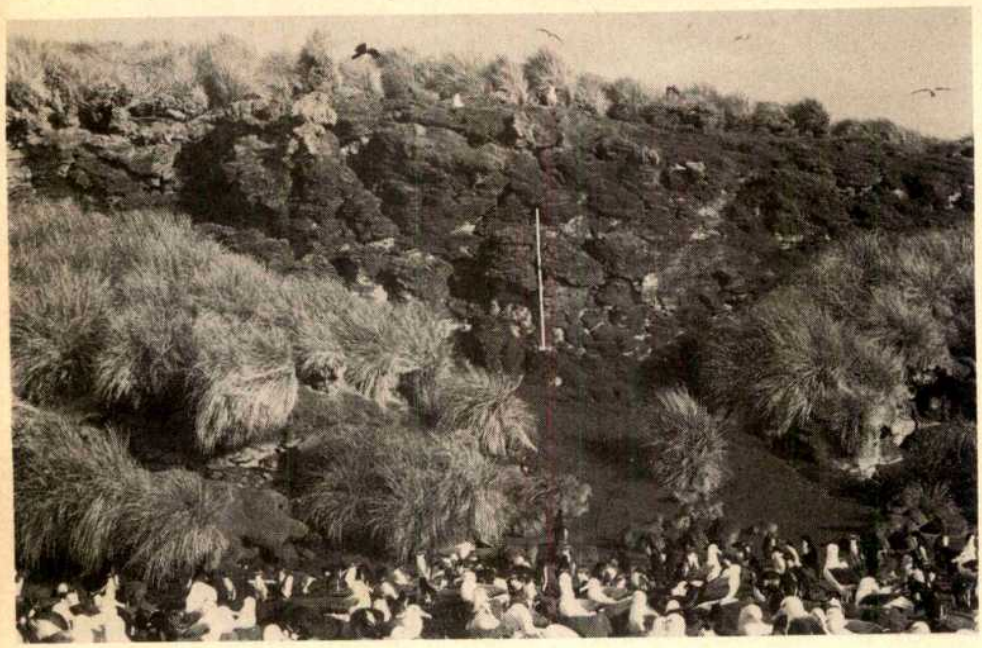

Fig. 1 An eroded cliff in the western edge of peat formed by tussac (*Poa flabellata*) grassland on Beauchêne Island in the South Atlantic. The birds in the foreground are part of a breeding colony of rockhopper penguins and black browed albatrosses. This is the site where our samples were taken. The white stake is 2.80 m long and the depth of peat from the base of the grass tussocks to the bedrock is 11.3 m. At the north-east edge of the island is a similar cliff in 5 m of peat.

The grassland grows on a deep mantle of peat composed of *Poa flabellata* litter. Along about one-third of the main bird colony the western edge of the tussac grassland is eroded into a steep and often near-vertical peat cliff (Fig. 1) along which the maximum recorded depth was 13.3 m.

Beauchêne Island has a cool temperate oceanic climate similar to, but probably cooler, drier and windier than, that of Port Stanley (Fig. 2) on the east side of East Falkland Island. It is similar to that of Tierra del Fuego. Compared with Moor House in the North Pennines of England, which has extensive blanket bog, the temperature regime is more equable with little frost, and the precipitation is much lower. Other regions of the Northern Hemisphere, such as Ireland, have extensive peat bogs with as equable a temperature regime as Beauchêne Island but even larger precipitation than Moor House. Yet others, such as continental Europe, North America and north Eurasia, have peat bogs with a much less equable temperature regime and similar precipitation.

The concentrations of inorganic species in leaves of one *Poa flabellata* plant and in three samples of surface peat from Beauchêne Island were determined[2]. These values are compared with some for North German surface peats (Table 1). The influence of sea spray is clear in the values for Na, but not in Mg. The cation exchange and chelating capacities of the Beauchêne Island peat are smaller than those of the North German peats, and this may reduce selectivity for higher valence ions. The absence of soil dust may partly account for the lower values of Ca, Fe and Al: the island rock is quartzite. Inorganic and total N are high in the Beauchêne Island peat, probably a consequence of the close proximity of so many nesting birds, but PO_4 concentrations are not very high. In the live plant there are higher concentrations (than in the peat) of NH_4 and especially of K. In general there seem to be no obvious deficiencies in the live plants, but the concentration of K in the peat may perhaps limit the activities of microorganisms, particularly at *p*H 3.7 which now prevails near the surface (Fig. 3).

The physical properties of the peat are unusual. The water content was measured on samples of peat stored for about 2 weeks in sealed polythene bags. The dry bulk density of air-dried peat was measured much later, but the results showed that during air-drying the peat had shrunk considerably. The dry bulk density of fresh peat was therefore measured indirectly by two methods. A sample was heated in water at 98 °C for 24 h. The peat was strongly coherent. Its volume was determined by displacement. The surface was blotted and the rehydrated fresh mass measured. Then the sample was put into a 'specific gravity' bottle whose mass was measured. Finally the sample was dried at 105 °C for 24 h and its mass measured. From the 'specific gravity' measurement the dry matter density, and then the volume of dry matter, were calculated. This, together with the fresh and dry mass, gave the wet volume of the rehydrated peat. The results agreed to within 5% with the direct measurements of volume. Next it was assumed that the difference in water content of the rehydrated sample and of the original wet peat gave a direct measure of the loss of volume from the peat in the fresh state and so, finally, the dry bulk density. The second method used the fact that the density of the dry matter (not the dry bulk density) changed approximately exponentially from 1.44 g cm^{-3} at 75 cm depth to 1.62 at 1,100 cm depth. With this information and the water content of the original wet peat, assumed water saturated, the minimum value of the dry bulk density was calculated. For nine samples below 125 cm deep, this calculation gave results within 3% of those obtained by the first method. This close agreement probably indicates that the dry bulk density values are sufficiently accurate and that the peat below 125 cm depth is water-saturated and hence probably anaerobic. The first method gave higher values than the second for the two topmost samples: 0.29 compared with 0.25 g cm^{-3} at 75 cm; 0.34 compared with 0.30 at 125 cm. This is consistent with some gas in the fresh peat at these depths, or with bias in the first method applied to these markedly less-coherent peats. Whatever the explanation it does not seriously affect the use of the dry bulk density values for the assessment of the peat

Table 1 Concentration of some inorganic species (μmol g^{-1}) and loss on ignition (%) on a dry mass basis

	Beauchêne Island		North Germany[9]
	Poa flabellata green leaf mid-lamina	Surface tussac peat: range of three values	Surface peat inter-quartile range
Na	160	120–150	2–10
K	490	2–10	10–60
½Ca	60	110–490	200–500
½Mg	70	83–130	160–800
⅓Fe	10	80–90	100–300
⅓Al	10	80–90	170–1,100
PO_4-P	180	6–120	30–650
NO_2+NO_3-N	0.5	0.8–5.4	<0.01–0.01
NH_4-N	240	9–27	1–15
Total − N	1,700	2,500–4,900	700–1,800
Loss on ignition	95	78–85	50–95

accumulation process (Fig. 3). In the absence of measurements of redox potential, however, we do not know the extent to which the surface layers are aerobic, and this is crucial in any attempt to understand the decay processes[3].

The bulk density of dry matter is unusually high for bog peat and the loss in mass on ignition was high (89–95%) so the high bulk density cannot be attributed to the presence of large amounts of inorganic matter. The bottom 150 cm of the peat are lignitic. Where this peat is exposed to the air it becomes black, rock-like, and breaks with a conchoidal fracture[2]. The field water content of this material is ~30% (of the dry mass) but about 1m in from the peat face the water content is ~200% and the peat has a very hard cheesy texture. True lignite is chemically altered by geothermal heat and is $>10^6$ yr old, yet ^{14}C dating shows that the lignitic peat is younger by several hundred-fold. The compressive stress at the base of a water-saturated peat may be quite small, because the effective weight is produced only by that part of the dry matter with density greater than that of water. Thus for a 10-m depth of water-saturated peat of dry bulk density 0.3 g cm^{-3} and with dry matter density 1.5 g cm^{-3}, the pressure will be $(1.5–1.0)\times0.3\times1{,}000 = 150$ g cm^{-2}.

The ^{14}C-age of 10 samples spaced down the peat profile was measured (Fig. 3) and is consistent with a rate of addition of dry matter of $p = 520–720$ (95% confidence limits) g m^{-2} yr^{-1} and of proportional rate of decay of $\alpha = 1.2\times10^{-4} – 2.2\times10^{-4}$ yr^{-1}. The asymptotic limiting depth, p/α, is 360 g cm^{-2} (there is ~330 g cm^{-2} at present). If the dry bulk density of this matter were ~0.35 g cm^{-3} then the limiting depth would be ~14 m. The position of the lowest two points may be seriously inaccurate because of the ^{14}C calibration extrapolation, and because they are in the lignitic peat which may affect the assumption of no more than two constant processes. So the topmost eight points alone were fitted too. They gave $p = 430–630$ g m^{-2} yr^{-1}, $\alpha = 1.1\times10^{-4} – 1.7\times10^{-4}$ yr^{-1}, and an asymptotic depth of 15 m.

These results are similar to those found for Fennoscandian peats[4] in that (1) depth, as cumulative mass, versus age curves appear to fit the single component, constant rate of addition, constant proportional rate of decay hypothesis surprisingly well; (2) independent of assumptions about the rate of decay, the rate of addition of dry matter has been nearly constant over thousands of years in spite of probable climatic changes; (3) the rate of decay of Beauchêne Island peat is within the range $(0.7–5)\times10^{-4}$ yr^{-1} for Fennoscandian peats; (4) the rate of addition, p, of dry matter to Beauchêne Island peat is about 10 times as great as the rate (35–78 g m^{-1} yr^{-1}) for Fennoscandian peats[4] (Fig. 3). The quoted Fennoscandian values of p are the rate of addition to the anaerobic peat and are ~10% of the net productivity of the vegation there. If the same were true on Beauchêne Island then net productivity would be about 5,500 g m^{-2} yr^{-1} which is an implausibly (but not impossibly) large value: the relative growth rate of *Poa flabellata* tillers in experiments[5,6] over the 24-week austral summer was 0.13 g g^{-1}, and a capital of 240 g m^{-2} invested with this growth rate would be sufficient to produce 5,500 g m^{-2} in 24 weeks. The dry green biomass in a site close to a seal wallow on South Georgia was 16,000 g m^{-2}.

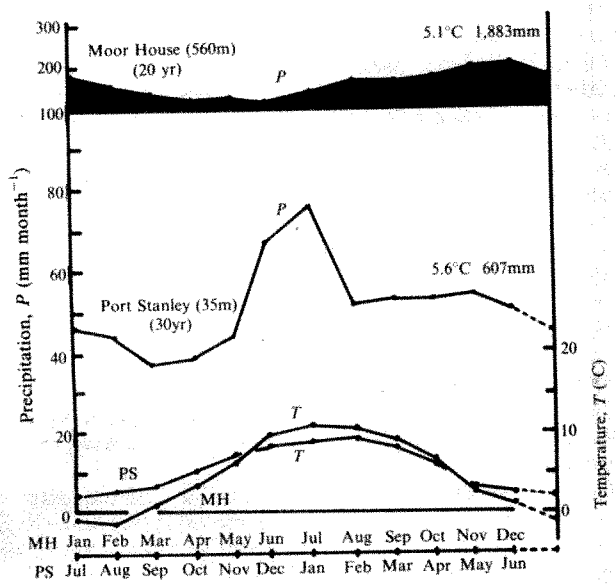

Fig. 2 Klimadiagramms (superimposed) for Port Stanley (PS), East Falkland Island and Moor House (MH), North Pennines, England.

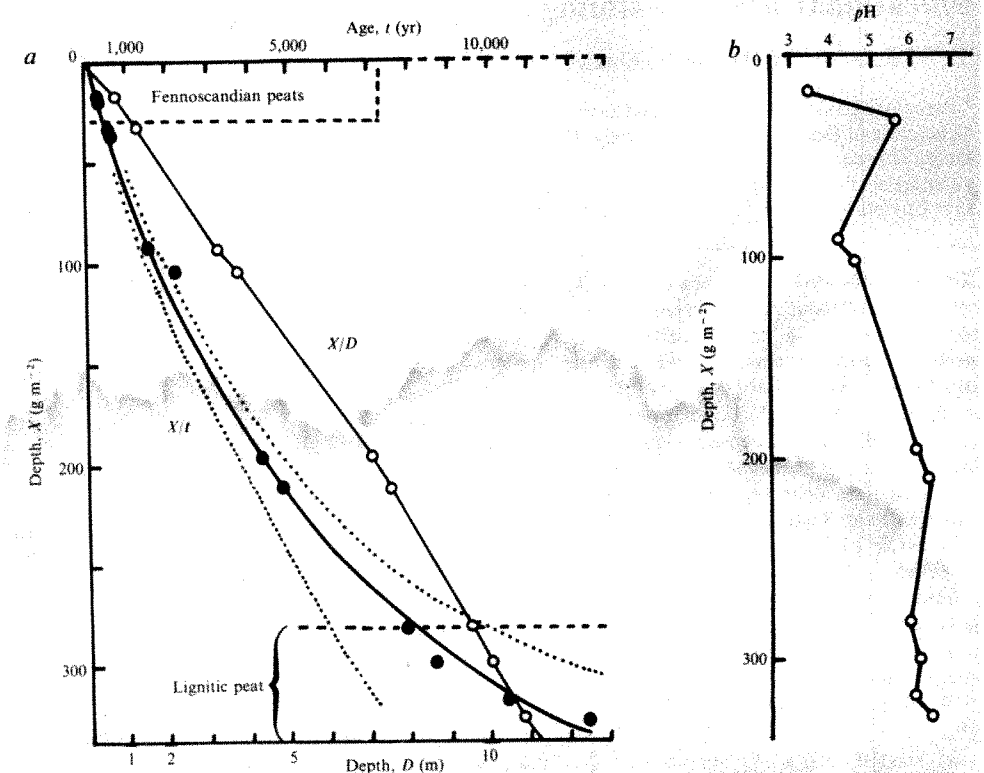

Fig. 3 *a*, Age, t, against depth as cumulative mass, X, and depth as distance, D, against depth as cumulative mass for a *Poa flabellata* peat profile on Beauchêne Island, South Atlantic. The 'true' age, t, of samples with ^{14}C age up to 6,500 yr was calculated using a dendrochronological calibration[10]. For the oldest thousand years of this calibration the deviation between ^{14}C and dendrochronological age is approximately constant and this deviation has been assumed to hold for older samples also. On this plot a constant rate, p, of addition of plant mass to the peat would give a straight line, and if there is decay in the peat a hollow curve results[3,4]. If the proportional rate of decay, α, is constant, and the peat is formed of a single component, then $X = (p/\alpha)(1-e^{-\alpha t})$. The fitted curve[4] is for $p = 620$ g m^{-2} yr^{-1} and $\alpha = 0.00017$ yr^{-1}. The estimated value of p is largely determined by the general slope of the line, and of α by the concavity. Dotted lines show 95% confidence limits. The box at the top left shows the approximate region occupied by peats in Fennoscandia[4]. *b*, *p*H against depth.

It is difficult to account for the Beauchêne Island peat. The concentration of inorganic elements in the plants reveals little about what limits the productivity of *Poa flabellata*. The species favours organic soils and is highly tolerant of sea-spray and biotic disturbance. Its luxuriance and productivity are enhanced wherever there are breeding populations of seals and seabirds. It is not known why the plant matter does not decay as rapidly as it forms. Populations of bacteria, yeasts and other fungi in the peat are high[2]. The temperature is not so low as to restrict decay in general. At the much colder sub-Antarctic South Georgia tussac peat accumulates to several metres in depth[7] yet decomposition of other organic matter proceeds quite rapidly[8]. Why then does peat accumulate on Beauchêne Island at all? And why is the rate of input to it so high at the same time as the decay rate is low? Part of the reason must be that the large input of volatilized nitrogenous compounds from the adjacent massive seabird colonies promotes rapid growth of the grass. In contrast, decomposition may be slow because of the low rainfall and high evaporation rates, caused by the almost perpetual strong winds, which together maintain a fairly dry substrate moisture regime in the surface layer of peat. In Arctic tundra peats a moisture content $<300\%$ inhibits microbial activity and decomposition rates. The water content of surface peat on Beauchêne Island is 250–350%. Potassium may also be deficient. The Beauchêne Island *Poa flabellata* peat raises fundamental issues about how peat forms, and would repay detailed study.

Heredity and familial environment in intelligence and educational level—a sibling study

T. W. Teasdale* & David R. Owen†

* Psykologisk Institut, Kommunehospitalet, 1399 Copenhagen K, Denmark and Department of Psychology, University of Lund, Lund, Sweden
† Department of Psychology, Brooklyn College, City University of New York, Brooklyn, New York 11210, USA

Although it is well established that family members resemble each other in intelligence[1], the extent to which this results from either shared genes or a shared environment remains controversial[2], perhaps especially since the relevant evidence presented by Burt has been shown probably to have been fabricated[3]. The influence of heredity and familial environment may be distinguished by studying adoptees. Here we present correlations in intelligence and educational level between genetically related pairs of adult adoptees who have been reared separately, and, conversely, between genetically unrelated pairs of adult adoptees who have been reared together. We are unaware of any previous study of adults which has reported on both of these types of relationship. The results for intelligence conform closely to what would be predicted by a simple polygenic model of genetic transmission whereas those for educational attainment imply both genetic and familial environmental components.

From a Danish adoption register[4,5] we have identified four groups of sibling pairs. The first three groups comprise genetically related pairs who were adopted and reared apart in separate families: full siblings reared apart (FA, 34 pairs), maternal half-siblings reared apart (MA, 52 pairs) and paternal half-siblings reared apart (PA, 41 pairs). The fourth group comprises genetically unrelated pairs who were adopted and reared together in the same families (UT, 27 pairs). All of these adoptees were male, born between 1938 and 1947. Their median age at transfer to their adoptive homes was 5 months, and 86% had been transferred by 2 years of age.

Intelligence and education data for these adoptees were obtained from draft board records. Danish conscription law requires males, on attaining the age of 18 (or shortly thereafter, and not later than 26 years old), to appear before a draft board. A medical examination is performed, educational level (EL) is recorded on a 9-point scale from 1 = minimum years of grade school (that is, 7) to 9 = university degree, and an intelligence test, the Børge Prien Prøve (BPP)[6], is administered.

The BPP is a 45-min group test consisting of four subtests covering broad areas of cognitive functioning: letter matrices (similar to Raven's progressive matrices), verbal analogies, number series, and geometric figure analysis. Each subtest comprises approximately 20 items arranged in order of increasing difficulty. The BPP score is the total number of correct answers.

BPP and EL scores, together with height, were traced in the draft board archives for 28 FA pairs, 34 MA pairs, 30 PA pairs and 24 UT pairs.

We have also identified a fifth group comprising 73 pairs of non-adopted brothers, that is, full siblings reared together by their biological parents (FT). These pairs, for whom height and BPP and EL scores were also available, are derived from a large sample of males used in another study[7] and differ somewhat from the adoptees. They were born between 1944 and 1947, they were almost all reared in Copenhagen rather than, as were the adoptees, distributed across Denmark, and they were at least 184 cm tall.

Quantitative predictions from a familial environmental or genetic hypothesis, regarding the degree of resemblance to be expected between such pairs of adopted and non-adopted siblings on any given measure, will to some extent depend on the parameters included and on the assumptions made. Heuristically, however, the following simplification may be proposed in terms of expected intraclass correlations (ρ): a strictly environmental hypothesis would predict zero correlations among all separately reared pairs and a positive correlation between those reared together corresponding to that found in intact families, for example, usually about 0.5 for IQ[1]; a strictly genetic hypothesis of polygenic transmission, by contrast, would predict correlations corresponding to the average proportion of shared genes, that is, 0.5 for full siblings, 0.25 for half-siblings, and 0.0 for unrelated individuals. These two hypotheses are extremes, and intermediate results would indicate the presence of both environmental and genetic influences.

The most fundamental assumption of an adoption study is that genetic and familial environmental factors are independent of each other in adoptees. We have no evidence to the contrary in the present study. The genetically related adoptee sibling pairs (FA, MA and PA) were reared in familial environments which, as measured by paternal income and social class, were uncorrelated (see Table 1); correspondingly, the absence of a correlation in social class between the biological fathers of the unrelated pairs (UT) fails to suggest that the pair members are genetically correlated.

The intraclass correlations ($\hat{\rho}$) for height, BPP and EL for each of the five groups, and for the two half-sibling groups combined, are shown in Table 2. We included height on the expectation that, whatever relationships emerged for BPP and EL, this variable would show a clear pattern of heritability. Although some genetic influence is evident, it appears anomalous that the correlation for the MA group should lie, albeit non-significantly, above that for the FA group while that for the PA group should be effectively zero. This may probably be attributed to the small group sizes and necessitates caution in interpreting our other findings.

Table 1 Means and intraclass correlations ($\hat{\rho}$) for adoptive and biological fathers' income and social class

	Annual income (×1,000 kroner)					Social class				
Adoptive fathers	No. of pairs	Mean	MS_b	MS_w	$\hat{\rho}$	No. of pairs	Mean	MS_b	MS_w	$\hat{\rho}$
Full sibs apart (FA)	25	5.587	7.611	11.014	−0.22	27	2.37	2.523	2.704	−0.07
Maternal half-sibs apart (MA)	32	4.524	6.397	5.377	0.05	32	2.41	2.788	1.781	0.19
Paternal half-sibs apart (PA)	26	5.073	7.361	7.980	−0.08	29	2.62	2.523	3.690	−0.22
Half-siblings apart (MA and PA)	58	4.770	6.860	6.544	0.01	61	2.51	2.642	2.689	−0.03
Unrelated reared together (UT)	22	7.202				24	4.21			
Biological fathers										
Unrelated reared together						15	1.33	1.405	1.933	−0.23

The intraclass correlation coefficient (ρ) is estimated as $\hat{\rho} = (MS_b - cMS_w)/(MS_b + cMS_w)$ where $c = \text{d.f.}_w/(\text{d.f.}_w - 2)$. $\text{d.f.}_w = N$ pairs. Being an estimate of a ratio of variances, a negative intraclass correlation is not meaningful. The negative values in the table are those obtained from the unbiased estimator and the best estimate in the range would be $\hat{\rho} = 0$. Details of paternal income and social class were obtained from the adoption records. Income was not recorded for the biological fathers. Social class is based on a rating scale of occupation in which 0 = low and 7 = high[4]. Both income and social class are missing in some cases and the values given are derived from all available complete pairs. The mean values are for all included fathers, that is, twice the number of pairs, except for the adoptive fathers for the UT group for whom the two potentially different values, one relating to each adoption, have been averaged. Analysis of variance (ANOVA) of the adoptive fathers' means for the FA, MA, PA and UT groups yielded $F(3,184) = 4.00$, $P < 0.009$ for income, and $F(3,196) = 8.38$, $P < 0.001$ for social class. Multiple range tests (Newman–Keuls, $\alpha = 0.05$) show, for income, UT > MA and UT > PA, and, for social class, UT > FA, UT > MA, and UT > PA. Note also that we have reported elsewhere[13], for a different but comparable sample from the adoption register, that the paternal social class of adoptees, while being on average above that of the general population, does not display a smaller variance, that is, adoptees in general were raised in a representative range of social class environments.

The correlations for the BPP form a pattern conforming closely to the proposed genetic hypothesis. There are no reported studies of separately-reared adult full or half- siblings with which these results may be compared, but the only previous study of genetically unrelated adults reared together has also reported a negligible correlation (−0.03)[8].

Studies of adoptive children have usually shown a lesser degree of genetic influence, and a correspondingly stronger familial environmental influence, on intelligence[1]; perhaps both vary with age. In particular, one might expect that not all genetic effects would yet be manifested by the still-developing brain of a child[9].

The correlations for educational level in the FA, MA and PA groups suggest a lesser degree of genetic influence on this variable and, conversely, the correlation for the UT group demonstrates a marked familial environmental effect. The latter correlation may reflect influences on scholastic aspirations and diligence. The high correlation for the FT group could thus be a result of the additive effect of both genetic and familial environmental influences.

Although the intraclass correlation remains a familiar statistic, it yields less information than a direct consideration of the within- and between-group mean squares, MS_w and MS_b respectively, from which it is derived. We have therefore also fitted biometrical genetic models to MS_w and MS_b, using maximum likelihood[11,14]. In a restricted model, the total variance consists of genetic variance, G, and environmental variance, E. For each sibling pair type, total variation (σ_t^2) is partitioned into 'within' and 'between' components: $\sigma_t^2 = \sigma_w^2 + \sigma_b^2$. The expectations for these components may be derived in terms of additive genetic variance, D_R, within-family environment, E_1, and between-family environment, E_2 (ref. 11). Expected values for the observed mean squares may be readily obtained as $E(MS_w) = \sigma_w^2$ and $E(MS_b) = \sigma_w^2 + 2\sigma_b^2$ for sibships of size = 2. Table 3 gives the expected values. Assumptions in the model are: (1) no genotype–environment interaction, (2) no genotype–environment covariance, (3) $G = 1/2\ D_R$, and (4) E_1 and E_2 values are the same for all types of sibship. We have no direct test of assumption (1) in these sibships. Assumptions (2)–(4) are jointly tested by the homogeneity of the total variances across sibling types (height $F_{max}(4, 56) = 1.38$, not significant (NS); BPP $F_{max}(5, 64) = 1.59$, NS; EL $F_{max}(5, 64) = 1.64$, NS), and also by the goodness of fit of the models ($P > 0.34$). Assumption (2) can also be tested by the equality of the total variance of biological siblings reared together and the pooled variance of the siblings reared apart (BPP $F_{max}(2, 161) = 1.16$, NS; EL $F_{max}(2,161) = 1.10$, NS).

For all three variables the model provides an adequate fit with additive genetic variance significant in all cases (see Table 4). Between-family environmental variance is significant for EL

Table 2 Means and intraclass correlations ($\hat{\rho}$) for siblings' height, intelligence (BPP) and educational level (EL)

		Height (cm)				BPP				EL			
	No. of pairs	Mean	MS_b	MS_w	$\hat{\rho}$	Mean	MS_b	MS_w	$\hat{\rho}$	Mean	MS_b	MS_w	$\hat{\rho}$
Full sibs apart	28	174.7	43.87	23.66	0.27	33.38	257.50	85.16	0.47‡	3.91	7.335	3.089	0.38*
Maternal half-sibs apart	34	175.3	63.67	28.12	0.36*	32.47	122.57	91.71	0.11	3.65	2.380	3.912	−0.27
Paternal half-sibs apart	30	175.7	31.23	34.67	−0.09	35.17	154.53	77.97	0.30*	4.13	4.446	2.667	0.22
Half-sibs apart	64	175.5	48.09	31.13	0.20*	33.73	139.02	85.27	0.22*	3.88	3.413	3.328	0.00
Unrelated reared together	24	177.0	36.69	31.42	0.03	37.75	157.22	138.88	0.02	4.96	6.214	2.292	0.43†

Being an estimate of a ratio of variances, a negative intraclass correlation is not meaningful. The negative values in the table are those obtained from the unbiased estimator (see Table 1), and the best estimate in the range would be $\hat{\rho} = 0$. The PA and MA & PA values for height are based on 29 and 63 pairs, respectively. Height was not recorded for one of the adoptees in the PA group; $\hat{\rho}$ is not calculated for the FT group because of the range restriction—all individuals were ≥184 cm. ANOVA for the four adoptee groups (FA, MA, PA and UT) yielded $F(3,228) = 4.32$, $P < 0.006$ for EL, and a multiple range test (Newman–Keuls, $\alpha = 0.05$) shows UT > FA, UT > MA and UT > PA. For BPP the overall comparison is not significant, $F(3,228) = 2.22$, $P > 0.09$, but an *a priori* comparison shows that the UT group is higher than the FA, MA and PA groups combined: $t(228) = 2.18$, $P < 0.03$.

* $P < 0.05$; † $P < 0.01$; ‡ $P < 0.005$; § $P < 0.001$.

only. Biometrical genetic modelling allows estimates of the effects of dominance deviation and assortative mating[10,11,14]; the results of the goodness-of-fit tests imply non-significance for both parameters in these data.

Some degree of familial environmental effect on intelligence and educational level can be detected in the means of the four adoptee groups. The adoptees in the UT group were reared in homes that were significantly wealthier and of a higher social class than those in the other three adoptee groups (see Table 1). Parents adopting more than one child were better situated than adoptive parents in general; this has elevated the intelligence and educational level of their adoptive children. Compared with the FA, MA and PA groups, the UT group adoptees have a significantly higher BPP and EL, the latter effect being more marked than the former (see Table 2). The mean differences in EL and BPP between the adoptees taken together (FA, MA, PA and UT) and the non-adopted siblings (FT) are not easily interpreted as either or both groups may deviate from the general population, and genetic or environmental differences may be involved.

The correlation between BPP and EL is 0.65 for all adoptees and 0.71 for the non-adopted siblings; this replicates the strong relationship usually found between intelligence and educational level[12]. These two variables are generally thought to interact with each other. As our findings suggest stronger genetic effects on intelligence than on educational level, it could be that genetic influences on educational level are indirect and operate primarily through genetic effects on intelligence. Conversely, however, the effects of familial environment on educational level appear stronger than the effects on intelligence. Therefore, the effect of familial environment on intelligence might be the indirect result of a direct influence of education itself on intelligence. In view of the comparatively small sample sizes used in the present study, and the (perhaps consequent) paradoxical findings for height, this interpretation must only be tentative.

We thank Drs S. S. Kety, D. Rosenthal, P. H. Wender and F. Schulsinger for permission to use the adoption register, and permission from the Danish Ministry of Defence, Centre for Leadership, and the Danish Ministry of the Interior, Department of Military Conscription, to collect the height, intelligence and education data (the assistance and advice of Majors Bendt Petersen and Erik Kousgaard, and Niels Jacobsen and Kitty Hansen were especially appreciated). Drs L. Kamin, S. S. Kety and T. I. A. Sørensen provided valuable discussion and comments.

Vertical disparity pooling and the induced effect

S. P. Stenton, J. P. Frisby & J. E. W. Mayhew

Department of Psychology, University of Sheffield, Sheffield S10 2TN, UK

If the image received by one eye is vertically magnified by a small amount then an illusory tilt is perceived around the vertical axis through the fixation point. This is known as the induced effect[1] and it can be explained by a recent computational theory of binocular vision[2–4] which treats it as a side-effect of the use of vertical disparities to recover information about the distance to the fixation point and the angle of gaze. We have investigated the consequences of introducing vertical magnifications of some parts of a scene and not others and report here that there is a simple linear relationship between the size of the induced effect and the average vertical magnification. This suggests that a pooling strategy is adopted in the measurement of vertical disparities, a result which fits in well with expectations of the theory.

The computational theory of binocular vision[2–4], which demonstrates how vertical disparities can be used to discover the distance to the fixation point (d) and the angle of gaze (g) with which the fixation point is being viewed, is introduced in ref. 5. One prediction of the theory is that vertical disparities produced by a monocular vertical magnification will lead the system to compute an incorrect angle of gaze[3]. Since this inappropriate value of g is then used to scale the horizontal disparities an erroneous left/right tilt of the entire field of view will result. This explanation of the induced effect will be called the 'd/g hypothesis'.

We have investigated how vertical disparity information is integrated from various parts of the field of view. We wished to know whether a mixture of vertical disparities that was incoherent, in the sense that it would not arise in normal viewing of natural scenes, would destroy the induced effect because it would then be difficult to compute the correct d and g from the conflicting information[3]. Alternatively, since the vertical disparities observed in normal viewing are quite small and perhaps difficult to measure accurately, the visual system might adopt a pooling strategy that would be reflected in an orderly relationship between the average magnification and the size of the induced effect created.

The experimental stimulus was an array of dots seen by binocular fusion of a pair of computer-controlled high-resolution x–y displays (Hewlett-Packard 1332A) that formed

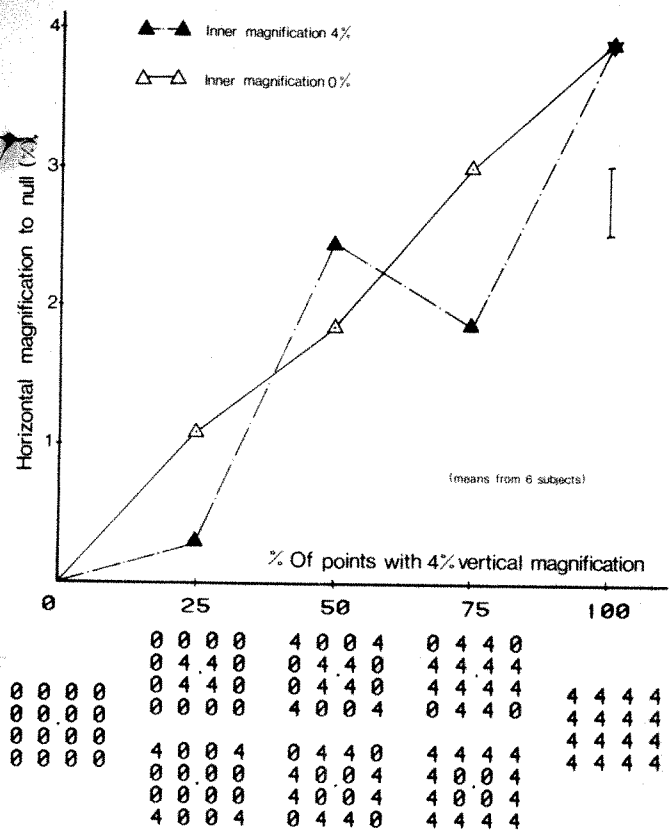

Fig. 1 Relationship between the size of the induced effect and the percentage of dots adjusted in position by a 4% monocular vertical magnification. Diagrams below the abscissa show the spatial distribution of dots whose positions were adjusted by 0% and 4% vertical magnifications. For the purposes of this graph (but not for the statistical analyses) each subject's mean setting for the 0% condition, which measured his subjective fronto-parallel plane, was subtracted from all points so that the plots illustrate directly the size of the induced effects. Solid triangles show means for the conditions where the four innermost dot positions were magnified (top row of diagrams); open triangles show means for conditions where the four innermost dot positions were unaltered (bottom row). The vertical bar on the right of the figure shows the mean standard error.

Methods: The dots had diameters of ~2.6 arc min, luminance of ~13.1 cd m^{-1} and could be positioned to an accuracy of ±0.2 arc min. They were arranged in a regular lattice except that the position of each dot was randomly displaced by up to ±8.5 arc min in both the x and y axis to avoid easily detectable shape cues associated with the various stimulus conditions. The overall size of the array was 7.2×7.2 deg visual angle.

the left and right fields of a Wheatstone stereoscope. Induced effects were created by altering the positions of selected dots in the right field. This simulates the effect of a meridional size lens, and gives a monocular magnification of the vertical projections of dots from the horizontal meridian through the fixation point[1]. Measurement of the induced effect was by a nulling technique which cancelled the induced effect with an opposite tilt illusion called the 'geometric effect'. The latter is also an illusory tilt around the vertical axis, but in the opposite direction, and is produced when the image received by only one eye is horizontally expanded by a small amount. This illusion was produced by simulating the effect of a meridional size lens with its axis vertical.

The subject was seated in a completely dark room, with his head position fixed by a forehead and chin rest. He saw about 40 cm away from him at eye level a 4×4 array of small bright dots with a fixation point at its centre (see Fig. 1 for details). At the start of each trial the display possessed some randomly-sized left/right tilt by virtue of the induced effect being measured having superimposed upon it an initial geometric effect, randomly selected within the range ±4.5%. Subjects were not informed of the source of the tilt they saw at any one time, whether it was induced effect, geometric effect or a mixture of the two. Their task was to press a pair of buttons until the array of dots appeared to lie in a fronto-parallel plane through the fixation point. A press on one button increased the nulling horizontal magnification by 0.5%, the other decreased it by 0.5%. Subjects were allowed to track to and fro over their null region before deciding on a setting, but training sessions ensured that they were able to make each setting within ~15 s.

Six subjects were used, each providing 10 settings per condition but with the largest and smallest eliminated to reduce experimental noise. Each block of 10 settings required about 3–5 min and to reduce fatigue successive blocks were separated by breaks of ~5 min during which subjects left the experimental room. A fuller account of the experimental design will be presented elsewhere[6].

All eight experimental stimuli are shown schematically below the abscissa in Fig. 1, where 0s and 4s indicate dots whose positions were adjusted by 0% and 4% magnification respectively. These 'mixed magnification' stimuli comprised two groups, distinguished by whether the vertical projections of the inner four dots of the array were 4% magnified or left unaltered. The two types permitted a preliminary exploration of the importance of the distribution of magnified points.

The results shown in Fig. 1 indicate that the induced effect created with uniform 4% vertical magnification was nulled by an opposing horizontal magnification of almost exactly equal size. This result replicates a well attested result regarding the relationship between induced and geometric effects[1] and suggests that the novel technique used here to measure the induced effect was satisfactory. The two types of mixed magnification stimuli did not produce significantly different tilts ($F[1, 5] = 1.258$, not significant), nor was there a significant interaction between that factor and the percentage of magnified points ($F[2, 10] = 3.036$, not significant). On the other hand, the magnitude of the induced effect increased with the percentage of magnified points ($F[4, 20] = 13.63$, $P < 0.0001$), with a trend analysis incorporating data pooled over the two types of mixed magnification stimuli showing only the linear trend to be significant ($F[1, 20] = 91.916$, $P < 0.0001$); slope of linear regression = 0.924).

This simple linear relationship suggests that the size of the induced effect is determined by the 'average vertical magnification' and implies that vertical disparity information from different parts of the field of view is pooled. The similarity between the two types of mixed magnification stimuli indicates that there is no significant difference in weighting between relatively central regions and peripheral ones. Pooling fits in well with the d/g hypothesis because viewing system parameters are intrinsically whole-field in character: as only one d and one g can exist at any one time, it makes sense to pool information about them, particularly if that information is delivered by vertical disparities which are inevitably small. The fact that vertical disparities are scaled by retinal eccentricity but unaffected by local variations in depth[3] would be compatible with a pooling mechanism that allows data to be pooled over relatively large areas.

There are a variety of ways in which vertical disparity information might be pooled. These might be divided into two broad classes distinguished by whether locally computed values of d and g are averaged or whether vertical disparity information is pooled before the computation of d and g. Whatever the particular scheme adopted by the human visual system, the result reported here suggests that an orderly pooling of vertical disparity information does occur.

Antibodies to heavy neurofilament subunit detect a subpopulation of damaged ganglion cells in retina

Ursula C. Dräger & Alois Hofbauer*

Department of Neurobiology, Harvard Medical School, Boston, Massachusetts 02115, USA

Neurofilaments (NFs) consist of three protein subunits with apparent molecular weights of 68,000 (68K), 145K and 200K, which are found closely associated in most but not all locations in the nervous system[1–4]. One of these exceptions is the inner retina of the mouse, where antibodies to 145K NFs label large ganglion cells throughout the extent of the cells, while antibodies to 200K NFs label only more distal portions of the optic axons but usually fail to label the ganglion cell somata and proximal axons[5,6]. Very rarely, however, and more often in old mice, anti-200K NF antibodies do label a ganglion cell completely[5]. To determine whether these rare, completely labelled cells reflect a pathological alteration, we cut the optic axons, and report here that after a few days some of the axotomized cells could be labelled completely, in a Golgi-like fashion, by anti-200K NF antibodies. These cells seem to represent the population that forms the projection to the bulk of the lateral geniculate nucleus, as suggested by their size, distribution and projection pattern. Hence, antibodies to the heavy NF subunit in combination with lesions may allow selective retrograde tracing of a subpopulation of ganglion cells, and such antibodies can be used to detect damage in NF-rich neurones at a very early stage, long before they eventually degenerate.

Neurones respond to axonal injury with the retrograde cell reaction—chromatolysis and displacement of the nucleus—which may be followed by recovery, or, for centrally projecting neurones in mammals, often by degeneration of the entire cell[7,8]. Lesions of optic axons cause retrograde degeneration of retinal ganglion cells in mammals, which in adults is a rather slow process that may take months to years[9,10]. The change in affinity to NF antibodies in response to axotomy described here for the retina represents another feature of the retrograde reaction that is pronounced only in the largest ganglion cells. A similar abnormal neurofilament labelling has been observed in lesioned peripherally projecting neurones, where it was attributed to neurofibrillar hypertrophy[11]. The abnormality in the retina, however, reflects primarily an antigenic change rather than an increase in neurofilaments.

The binocular visual field in the mouse is largely located above the head, and is seen by the lower temporal retina. Some of the ganglion cells in this retinal region project to the brain on the same side, where they join the projection from the opposite eye, a convergence that forms the substrate for binocular vision[12]. Thus, when the optic tract on one side is lesioned, the effect of axotomy can be compared with the normal condition in the same retina, ipsilateral to the lesion. In the nasal retina, representing normal conditions (Fig. 1*b*), optic axons labelled by anti-200K NF antibodies can be followed from the optic disk for only a limited distance; ganglion cell somata and proximal stretches of axons remain invisible. In contrast, in the lesioned cells in the lower temporal retina (Fig. 1*a*) the reaction with the antibodies extends to the proximal axons, cell somata and dendrites, as also seen at higher power in Fig. 2. The labelled cell bodies were large (17.2 ± 1.8 μm mean diameter, $n = 207$), rather regularly spaced, and were probably identical to the large, NF-rich ganglion cells seen in normal mouse retina using methods that detect NF subunits of lower molecular weight[6,13,14]. Camera lucida drawings of all labelled ganglion cells ipsilateral to the optic tract lesion (Fig. 3*a*) showed about 300 cells (312 ± 14, $n = 6$), representing about one-third of all ipsilaterally projecting cells in the mouse[12].

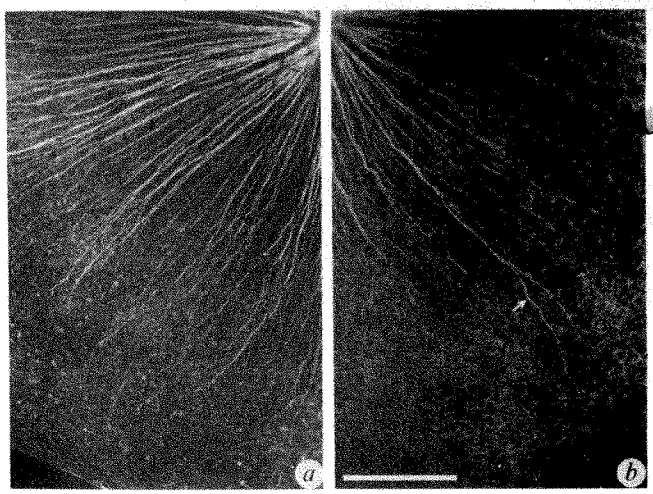

Fig. 1 Whole-mount of mouse retina showing effect of axotomy. A young adult C57BL/6J mouse was anaesthetized with Nembutal, and one optic tract was exposed and sectioned. After 10 days the mouse was perfused with paraformaldehyde and the retinas were reacted with an anti-200K NF antibody; here RT97 was applied[21], which gave results similar to the anti-200K NF antibodies R3 (ref. 5), 06-17 (ref. 22), 4.3F9 and 2.2F3 (ref. 23) used in other preparations. Antibody binding was visualized with a fluorescein isothiocyanate-labelled secondary antibody (Boehringer-Mannheim). Shown here are sectors from the retina ipsilateral to the optic tract lesion. *a* Includes part of the retinal representation of the binocular visual field which sends a projection to the ipsilateral side of the brain. *b*, Retinal sector corresponding to the monocular field represented only in the contralateral brain; hence the ganglion cells here were not affected by the optic tract lesion. The position of the optic disk, just above the upper margin in both views, can be inferred from the converging optic axons; the ciliary edge of the retina is visible in the lower corners of the figure. The textured background of the entire retina is due to labelling of the NF-rich axonless horizontal cells in the outer retina[24]. Note that in the unaffected retinal sector (*b*) the labelling of optic axons increases in intensity towards the optic disk, and even the longest axon segments visible cannot be traced much further than about half-way through the extent of the retina. In the sector containing axotomized ganglion cells (*a*), however, some optic axons can be followed all the way to their cell bodies, which are barely visible at this magnification in the peripheral retina. The increasing affinity of anti-200K NF antibodies for more distal portions of axons in normal conditions is further illustrated by the fibre indicated by an arrow in *b*: for this fibre the segment in the retina was the distal portion of the axon; it entered the retina through the optic disk and gave off branches on its course, a characteristic of efferent fibres (called efferent with respect to the brain[25]). It is unknown where the cell bodies of such efferent fibres in the mouse are located. Scale bar 500 μm.

In contrast to the limited retinal region giving rise to the ipsilateral retinofugal projection, contralaterally projecting ganglion cells are known to originate from the entire retina, and to outnumber the ipsilateral projection by about 60 to 1 in the mouse[12]. After the induction of optic tract lesions, however, the ganglion cells that assumed Golgi-like affinity to 200 K NF antibodies in the retina contralateral to the lesion formed a small subpopulation: about 1,000 cells were labelled, representing ~2% of the contralateral projection. The labelled cells were large and regularly distributed throughout the retina except for the lower temporal region which consistently contained only a scattered few labelled cells; this sparsely labelled region corresponded to the ipsilaterally projecting region in the other retina (Fig. 3*b*). Hence, a lesion of optic axons caused abnormal affinity for anti-200K NF antibodies in a subpopulation of ganglion cells which cover the retina more or less evenly and which have a line of decussation in their projections to one or the other side of the brain.

Such a pattern of projections is compatible with retinal inputs to the geniculo-cortical system but not to the optic tectum, as

* Present address: Max-Planck-Institut für Psychiatrie, München, FRG.

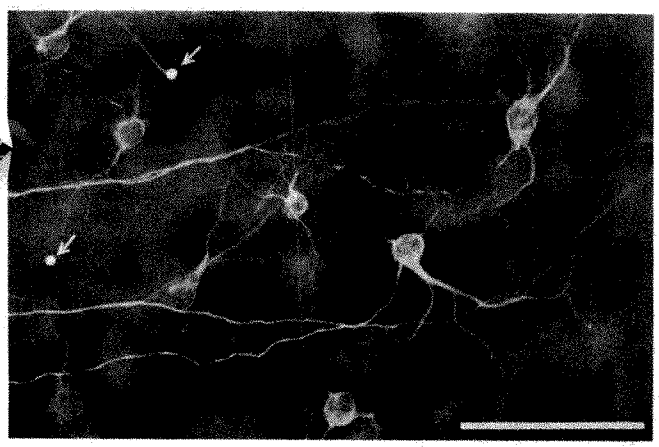

Fig. 2 Ganglion cells in retina ipsilateral to an optic tract lesion made 15 days previously, labelled for 200K neurofilaments with RT97 (ref. 21). These cells were the largest ganglion cells and formed about one-third of the entire ipsilateral projection[12]. Arrows indicate neurofilamentous clubs[8] that may represent the axons of some of the smaller axotomized ganglion cells. Such neurofilamentous clubs appeared a few days after the optic tract lesion and increased in frequency with time. They are also visible as bright specks in Fig. 1*a*. Scale bar, 100 μm.

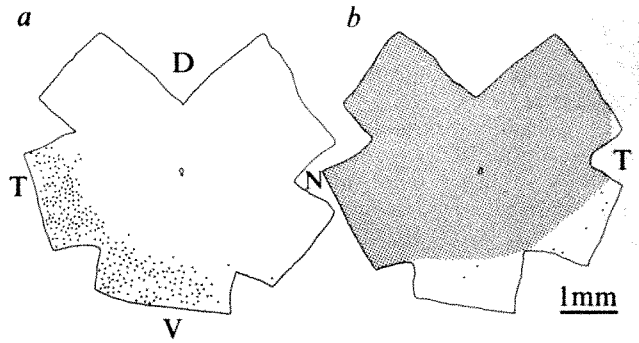

Fig. 3 Camera lucida tracings of ganglion cells labelled by anti-200K NF antibodies after optic tract section 6 days previously. Ipsilateral to the lesion (*a*) the labelled ganglion cells were regularly spaced within a crescent-shaped area in the ventral and temporal retina. The inner border of this crescent corresponds to the zero vertical meridian of the visual field[12]. Contralateral to the lesion (*b*) the bulk of the labelled cells were located in the shaded area. Their number could only be estimated (~1,000) because in more central retinal regions they were frequently obscured by heavily labelled bundles of optic axons. A crescent-shaped area corresponding to the ipsilateral projection was largely free of labelled ganglion cell bodies except for a scattered few. This region did, however, contain neurofilamentous clubs like those described in Fig. 2. V, ventral; D, dorsal; N, nasal; T, temporal.

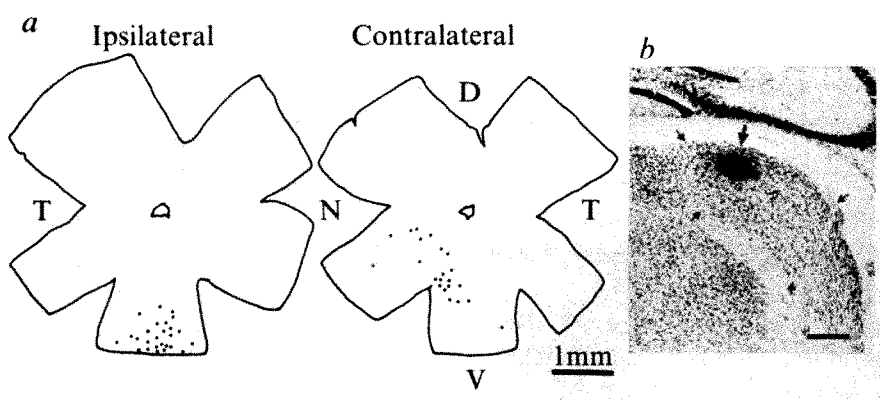

Fig. 4 Identification of ganglion cells projecting to the geniculate, using horseradish peroxidase (HRP) injections. Mice were anaesthetized with Nembutal, and visual responses were recorded from the lateral geniculate nucleus, using standard electrophysiological techniques with KCl-filled glass pipettes[26]. When a desired location within the geniculate was identified, the electrolyte was exchanged *in situ* against a solution of HRP, a tiny amount of which was then ejected electrophoretically. After 2 days the mice were perfused and the brains and retinas reacted for HRP. *a*, Camera lucida tracings of retinal whole-mounts showing positions of ganglion cells back-filled with HRP from a location in the lateral geniculate nucleus representing the upper binocular field of vision. *b*, Coronal section through the geniculate, reacted for HRP and counterstained with cresyl violet; the injection site is indicated by the large arrow, the geniculate borders by small arrows; scale bar, 200 μm. The labelled cells were from the largest population: 17.9 μm mean diameter ($n = 53$) ipsilateral to the injection and 15.6 μm ($n = 176$) contralaterally, and they were regularly spaced with comparable density and cell numbers in the two retinas. All injections into the main body of the lateral geniculate resulted in similar retinal labelling patterns, but it is possible that a population of smaller ganglion cells project to the outer shell of this nucleus. Comparable small injections into the most superficial layer of the superior colliculus label tight clusters of small ganglion cells, and deeper regions of the visual collicular layers receive a sparse and divergent input from large ganglion cells, which may be a collateral projection from the same cells that supply the lateral geniculate nucleus[26].

judged from physiological recordings. Each tectum contains a map of the entire contralateral retina, and the ipsilateral eye influence is very sparse[15,16]. The visual field representation in cortex, however, does not include the ipsilateral field (except for some infringement at the midline), and within the binocular field the influence of the ipsilateral eye is comparable with that of the contralateral eye[17]. However, although physiological observations point to a line of decussation in retinogeniculate projections, such a dividing line has never been observed anatomically in adult rodents (ref. 18 but see ref. 19). To identify the ganglion cells projecting to the geniculate, we injected horseradish peroxidase (HRP) into this nucleus. All injections confined to the main part of the geniculate labelled a population of largest ganglion cells that were spaced widely and rather regularly. When HRP was injected into the representation of the binocular field, populations of ganglion cells similar in size and spacing were labelled in both eyes (Fig. 4). In spacing, cell size and comparable bilateral distributions, the projections to the geniculate were indistinguishable from the cells that expressed the NF abnormality following optic tract lesions. This makes it likely that the line of decussation in the projections of the NF-rich ganglion cells is the anatomical substrate that accounts for the physiologically observed absence of ipsilateral field representation in visual cortex.

The time lapse to the appearance in the cell bodies of the antigenic change in response to lesions depended on the distance of the axotomy from the eye; it took about 6 days following optic tract lesions, and about 3 days after optic nerve cuts, suggesting the retrograde transmission of an injury message at ~1.5 mm per day. The antigenic change persisted for several weeks, but seemed to reverse gradually; 60 days after the lesions only a few cell bodies were still labelled, but the labelled axon segments were still extended, indicating that the cells had probably not degenerated yet but were undergoing some temporary recovery.

Here we have shown that antibodies to the heavy NF subunit which normally fail to label proximal neuronal regions, do so following lesions of the axons. The inability to label proximal cells normally may reflect the absence of the heavy NF subunit from this location, or, more likely, an affinity of the antibodies for a modified site that is slowly created as the neurofilaments are transported down the axon. The latter explanation was suggested by the Sternbergers, who showed that several anti-200K NF antibodies are directed against phosphorylated sites

not present in cell bodies[20]. Thus, one possible explanation is that the pathological changes observed here indicate atopic phosphorylation of neurofilaments in response to injury.

We thank Drs V. Lee, L. Sternberger and J. Wood for gifts of anti-NF antibodies, and S. Cinsavich and S. Hardy for technical assistance. This work was supported by NIH grant EY 01938, a Milton fund grant and a fellowship from the Deutsche Forschungsgemeinschaft.

Amplification of specific DNA sequences correlates with multi-drug resistance in Chinese hamster cells

Igor B. Roninson*, Herbert T. Abelson†, David E. Housman*, Neil Howell† & Alexander Varshavsky*

* Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA
† Dana-Farber Cancer Institute, Boston, Massachusetts 02115, USA

Mammalian cells selected for resistance to certain cytotoxic drugs frequently develop cross-resistance to a broad spectrum of other drugs unrelated in structure to the original selective agent[1,2]. This phenomenon constitutes a major problem in cancer chemotherapy. Multi-drug resistance arises from decreased intracellular drug accumulation[1–4], apparently due to an alteration of the plasma membrane[2,5–7]. The observation of double minute chromosomes or homogeneously staining regions in some of the multi-drug-resistant cell lines[8–12] suggests that gene amplification underlies this phenomenon. We have used the technique of DNA renaturation in agarose gels[13] to detect, compare and clone amplified DNA sequences in Adriamycin- and colchicine-resistant sublines of Chinese hamster cells[3,12]. We show that both Adriamycin- and colchicine-resistant cells contain amplified DNA fragments, some of which are amplified in both of these independently derived cell lines. Furthermore, loss of the multi-drug resistance phenotype on growth in the absence of drugs correlates with the loss of amplified DNA. These results strongly suggest that the DNA sequences which are amplified in common in multi-drug-resistant cell lines include the gene(s) responsible for a common mechanism of multi-drug resistance in these cells. We have cloned one of the commonly amplified DNA fragments and show that the degree of amplification of this fragment in the cells correlates with the degree of their drug resistance.

Table 1 Multi-drug resistance and 1.1-kb fragment amplification in different cell lines

Cell line	Relative resistance to: Adriamycin	Colcemid	Degree of 1.1-kb fragment amplification
V79	1	1	1
77A	5	7	5
LZ	3,000	436	60
LZ revertant	7		10
CHO Aux Bl	1	1	1
C5	150	280	20

Isolation and characterization of the Adriamycin-resistant sublines of V79 cells, 77A and LZ, have been described previously[12,23]. Cell lines CHO Aux B1 and C5 (ref. 3) were gifts from Dr V. Ling (University of Toronto). LZ revertant cells were obtained by growing LZ cells for 130 cumulative doublings in the absence of drug selection[12]. The degree of drug resistance of C5 cells was determined as described[23]. The degree of amplification of the 1.1-kb fragment I in different cell lines was determined from Southern blots (Fig. 2*a*) and from slot-blots (Fig. 2*b*) by cutting out and counting the bands of ^{32}P-labelled DNA.

The Chinese hamster cell lines used here are listed in Table 1. LZ, a highly Adriamycin-resistant subline of V79 cells, was obtained from a weakly resistant line 77A by multistep selection with increasing concentrations of Adriamycin[13]. The 3,000-fold degree of Adriamycin resistance in the LZ line is unstable, as LZ cells revert to an ~7-fold degree of Adriamycin resistance after prolonged growth in the absence of the drug[12]. In addition to Adriamycin, LZ cells are cross-resistant to several other drugs, including colcemid, a close analogue of colchicine[12]. C5, an independently derived subline of CHO cells selected for resistance to colchicine, is also resistant to multiple cytotoxic drugs[3]. LZ cells are relatively more resistant to Adriamycin than to colcemid (Table 1), whereas C5 cells are more resistant to colcemid than to Adriamycin. Indeed, it has been frequently observed that multi-drug-resistant cell lines are relatively more resistant to the drug used for their selection[1,2,8,10]. Such specificity suggests that while a common genetic alteration may have led to multi-drug resistance in different cases, additional genetic events may have further modified the pattern of drug resistance in different lines.

DNA from different cell lines was digested with *Bam*HI, and a portion of each DNA preparation (tracer DNA) was ^{32}P-labelled with T4 DNA polymerase[13]. Tracer DNA was mixed with an excess of unlabelled (driver) DNA and electrophoresed in an agarose gel. Following electrophoresis, DNA in the gel was subjected to two cycles of denaturation, renaturation and *in situ* digestion with S_1 nuclease to enhance selectively the signal from reiterated DNA fragments[13]. When both tracer and driver DNA derive from the same DNA preparation, this treatment produces a series of bands corresponding to the *Bam*HI restriction fragments that are reiterated at least 15–30 times per haploid mammalian genome. When tracer and driver DNA are from different DNA preparations, only those DNA fragments that are reiterated both in the tracer and in the driver are detected[13]. As the amplified chromosomal domains are known to contain varying amounts of flanking sequences that have been co-amplified together with the essential gene[14,15], identification of the commonly amplified sequences in different independently derived cell lines by the above procedure allows one to delineate the region which is likely to contain the gene of interest.

Figure 1 shows the results of experiments in which DNA was electrophoresed and then subjected to the treatment described above in either a 1% (Fig. 1*a–l*, *u–x*) or 0.7% (Fig. 1*m–t*) agarose gel. Several bands corresponding to repeated *Bam*HI fragments of hamster DNA are observed in the digest of parental V79 DNA (Fig. 1*a*, *m*, *u*). DNA from the weakly resistant line 77A (Fig. 1*b*, *n*) gives a pattern which is indistinguishable from that of V79. However, in the digest of LZ DNA (Fig. 1*c*, *o*, *v*)

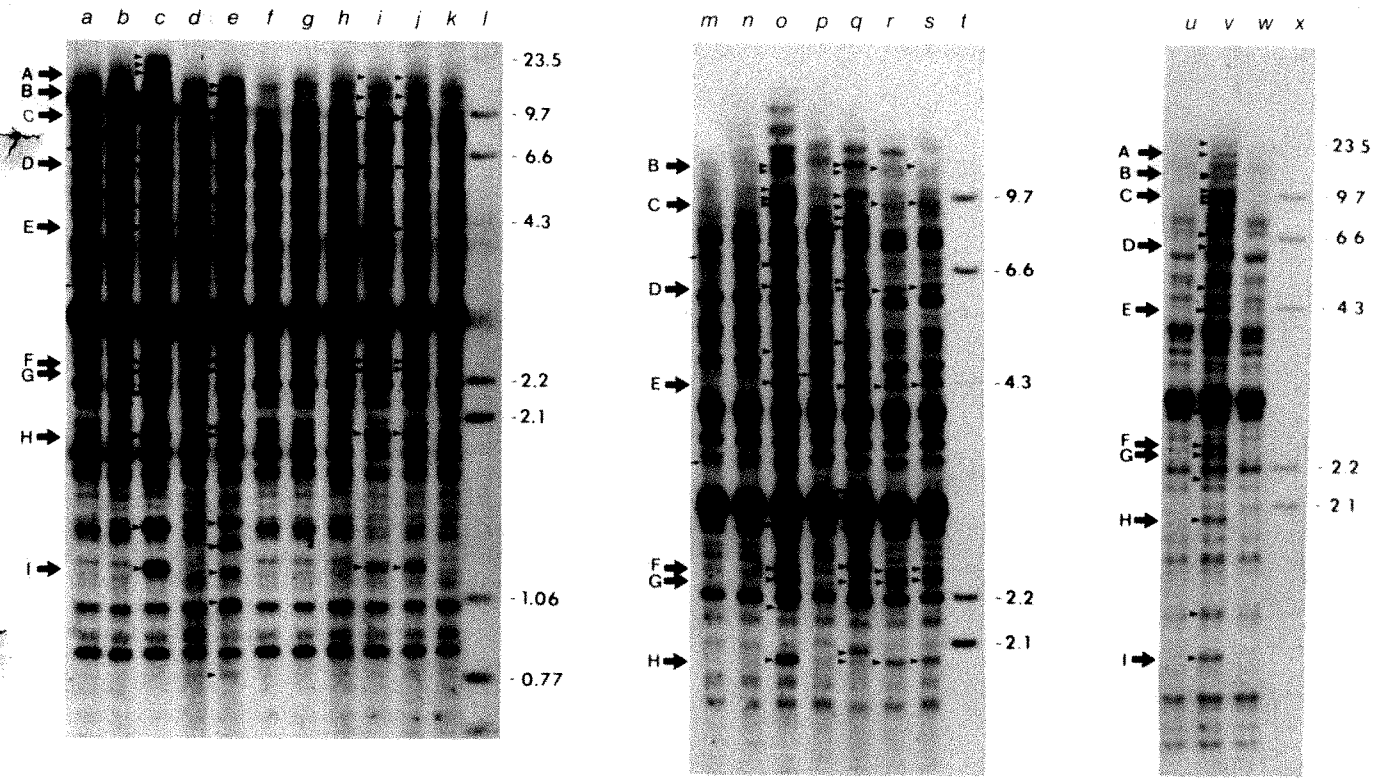

Fig. 1 Identification of amplified DNA fragments by in-gel DNA renaturation. Lanes *a–l*, *v–x*: 1% agarose gel; lanes *m–u*: 0.7% agarose. Each lane contains *Bam*HI digests of the following DNA samples: *a*, *m*, *u*, V79 (tracer and driver); *b*, *n*, 77A (tracer and driver); *c*, *o*, *v*, LZ (tracer and driver); *d*, *p*, CHO Aux Bl (tracer and driver); *e*, *q*, C5 (tracer and driver); *f*, LZ (tracer), V79 (driver); *g*, *γ*, hLZ (tracer), 77A (driver); *h*, 77A (tracer), LZ (driver); *i*, *r*, LZ (tracer), C5 (driver); *j*, *s*, C5 (tracer), LZ (driver); *k*, C5 (tracer), CHO Aux Bl (criver); *w*, LZ revertant (tracer and driver). *Hin*dIII fragments of λ phage DNA (*l*, *t*, *x*) and *Hin*cII fragments of ΦX174 RF DNA were used as size standards (*l*, *t*, *x*). Amplified DNA fragments are indicated by arrowheads. A subset of DNA fragments amplified in both LZ and C5 cells (A–I) are marked by arrows. Small arrows indicate the differences between the V79 and CHO DNA patterns (*a*, *d*, *m*, *p*). Several bands at the top of lanes *m–t* are missing because of gel breakage in this experiment.

Methods: DNAs from the different cell lines were extracted by the procedure of Blin and Stafford[24]. DNA was digested with *Bam*HI and tracer DNA was labelled with ^{32}P using T4 DNA polymerase and [α-^{32}P]dCTP (3,000 Ci mmol^{-1}) in conditions where an average of ~100 nucleotides were excised from each 3′ end in the exonuclease reaction before resynthesis[13]. DNA was separated in a 30.5 × 24 × 0.4 cm agarose gel. After electrophoresis, the gel slab was cut to 28.5 × 16.3 cm, placed in a flat-bottomed plastic box and subjected to two cycles of in-gel renaturation and S_1 nuclease digestion as described[13] with the following modifications. The composition of the hybridization buffer was 0.9 M NaCl, 0.5 mM EDTA, 50% formamide, 0.05 M Na-phosphate (*p*H 7.0). The buffer volume used for washes was 350 ml, and S_1 nuclease digestion was done in 250 ml of digestion buffer[13] containing 20,000 units of S_1 nuclease, after five 15-min washes with the digestion buffer. Each lane was loaded with either 1.36×10^7 d.p.m. in 0.35 μg (*a–k*, *m–t*) or 1.0×10^7 d.p.m. in 0.5 μg (*u–x*) of tracer DNA and 15 μg of unlabelled driver DNA.

a large number of additional bands can be detected, indicating the presence of amplified DNA in these highly drug-resistant cells. These bands were undetectable when V79 or 77A DNA was used either as a tracer or as a driver in hybridization with LZ DNA (Fig. 1*f*, *g*, *h*). The sizes of the amplified DNA fragments in the LZ DNA are ~150 kilobases (kb) in total, which should be considered the minimum estimate for the size of the amplified chromosomal domain in LZ cells (assuming that all of the amplified fragments are contiguous in the genome). In contrast, the amplified fragments were not detected in the DNA of the LZ cells that have reverted to a low degree of drug resistance after prolonged growth in the absence of Adriamycin (Fig. 1*w*). The loss of the amplified DNA fragments thus occurred concurrently with the loss of drug resistance in these cells, strongly suggesting that amplification of these DNA sequences underlies the drug resistance phenotype in LZ cells.

Comparison of the in-gel renaturation patterns produced by DNA from colchicine-resistant C5 cells (Fig. 1*e*, *q*) and from parental CHO DNA (Fig. 1*d*, *p*) reveals the presence of several amplified *Bam*HI fragments in C5 DNA; these fragments were not detected when CHO DNA was used as a driver (Fig. 1*k*). The amplified fragments in LZ and C5 DNA were compared in experiments in which LZ DNA was used as a tracer and C5 DNA as a driver (Fig. 1*i*, *r*) and vice versa (Fig. 1*j*, *s*); from the results we identified nine fragments (A–I) of total size ~55 kb that have been amplified in both LZ and C5 genomes. Amplification of the same DNA sequences in two cell lines that had been independently selected for resistance to different drugs strongly suggests a common mechanism for multi-drug resistance in these two cell lines. The gene(s) responsible for this mechanism is probably contained in these commonly amplified DNA sequences.

While the DNA fragments that are amplified in both LZ and C5 cells appear as a subset of strong bands in LZ DNA (Fig. 1*c*, *o*), the corresponding bands in C5 DNA (Fig. 1*e*, *q*) are barely detectable against the background. On the other hand, the digest of C5 DNA contains several strong bands of amplified DNA with a total size of ~70 kb, none of which is also amplified in LZ DNA. The result suggests that C5 DNA contains at least two different sets of amplified DNA fragments, which may correspond to two different amplified chromosomal domains. The domain that overlaps with the amplified domain in LZ DNA is amplified weakly in C5 cells, while the other set which is unique to C5 DNA is amplified to a greater degree. The latter sequences may carry the gene(s) specifying an additional mechanism for drug resistance in C5 cells, possibly specific for cells selected for colchicine resistance.

To address the nature of the gene(s) contained in amplified DNA, we have cloned one of the *Bam*HI fragments that have been commonly amplified in LZ and C5 DNA (the 1.1-kb fragment I in Fig. 1). LZ DNA (100 μg) was digested with *Bam*HI and separated in a 1% agarose gel. Positions of the

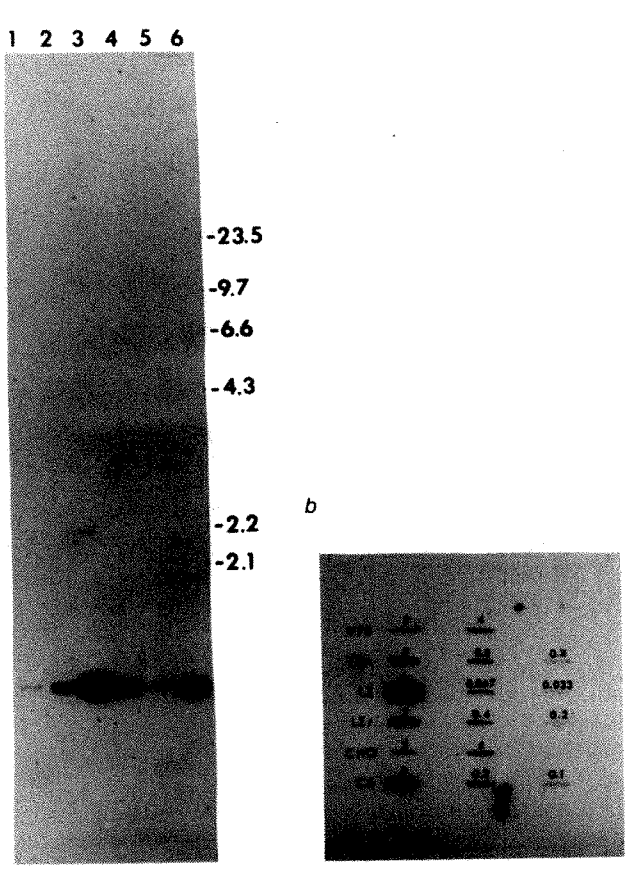

Fig. 2 Southern blot (*a*) and slot-blot (*b*) hybridization of the plasmid pDR1.1 with genomic DNA. *a*, DNA was extracted from V79, 77A, LZ, LZ revertant, CHO Aux B1 and C5 cells (lanes 1–6, respectively) and digested with *Bam*HI. Positions of the size standards are indicated. *b*, The source and amount (in μg) of DNA in each slot are indicated.

Methods: *a*, Cellular DNA (5 μg) was digested with *Bam*HI, electrophoresed in a 1% agarose gel and transferred to a nitrocellulose filter[18], then hybridized with 3×10^7 d.p.m. of pDR1.1 plasmid DNA (specific activity 2×10^8 d.p.m. μg^{-1}) that was labelled with ^{32}P by nick-translation[25]. Hybridization was done at 65 °C in 5× SSC, 2× Denhardt's, 0.1% SDS, 100 μg ml^{-1} denatured salmon sperm DNA. After hybridization the filter was washed with 0.1× SSC, 0.5% SDS at 65 °C and autoradiographed. *b*, DNA was bound to nitrocellulose filters as described[19]. The blot was hybridized with 3×10^7 d.p.m. of the pDR1.1 probe. Hybridization and washing were as described for *a*.

amplified fragments were established by in-gel renaturation[13] of the lanes containing ^{32}P-labelled V79 and LZ DNA digests separated in the same gel. A narrow strip of the gel containing fragment I was cut out and subjected to two cycles of denaturation and renaturation. S_1 nuclease was not used in this protocol so that the reannealed fragments would retain the cohesive ends generated by *Bam*HI. The mixture of single-stranded and double-stranded DNA (the latter enriched in repeated DNA fragments after renaturation) was eluted from the gel and ligated to the *Bam*HI-cleaved pBR322 plasmid. Only double-stranded DNA could be ligated at this step. The recombinant plasmids were used to transform *Escherichia coli* HB101 (ref. 16), and plasmid DNA from the resulting ampicillin-resistant/tetracycline-sensitive colonies was analysed by mini-scale DNA extraction[17] and digestion with *Bam*HI and *Hin*fI. Of 35 samples of the recombinant plasmids, seven produced identical restriction patterns, indicating that the corresponding clones contained DNA inserts that were reiterated in the genome (data not shown). DNA from one of these clones, designated pDR1.1, was used as a probe for Southern hybridization[18] with *Bam*HI-digested genomic DNA. Figure 2*a* shows that the cloned 1.1-kb fragment is amplified in all drug-resistant cell lines relative to the parental lines, and that pDR1.1 does not hybridize to any bands other than the 1.1-kb fragment and therefore does not contain interspersed DNA repeats. The degree of amplification of the 1.1-kb fragment was quantitated using both Southern blot[18] (Fig. 2*a*) and slot-blot[19] (Fig. 2*b*) hydbridization procedures. The results of these assays, summarized in Table 1, indicate an approximately linear correlation between the degree of amplification of the 1.1-kb fragment and the degree of Adriamycin resistance in the weakly resistant cell lines, while in the highly resistant lines LZ and C5, the relative increase in drug resistance strongly exceeds the relative increase in the copy number of the 1.1-kb fragment. The latter result may be due either to additional genetic changes in the highly resistant cell lines (such as the amplification of the second set of DNA fragments in C5 cells discussed above), or to changes in transcriptional regulation of the amplified gene(s) at a high degree of amplification, or to the saturable nature of a biological process regulated by the product of the amplified gene(s).

The finding that gene amplification underlies the multi-drug resistance phenotype is of particular interest as this type of drug resistance does not result from overproduction of the drug targets[3], which is the case in all the other known instances of drug resistance due to gene amplification[20,21]. The nature of the protein(s) encoded by the amplified gene(s) is unknown, although the 170,000-molecular weight membrane glycoprotein and the 19,000-molecular weight cytosol protein that are frequently overproduced in multi-drug-resistant cells[1,2,6,10,22,26,27] are likely candidates. Recently, we have isolated several phage clones containing the sequences of pDR1.1 from a genomic library of LZ DNA (P. Gros and D.E.H., unpublished). These clones are being analysed for the presence of transcribed DNA sequences and for the ability to transfer multi-drug resistance via DNA transfection. Once the specific DNA segments containing the gene(s) responsible for multi-drug resistance are identified, they will be used to isolate the corresponding protein(s). Understanding the phenomenon of multi-drug resistance in tumour cells may help in the design of treatments that would be selectively cytotoxic for the resistant cells.

We thank Carolyn Gorka for technical assistance and Cathy Thurmond for typing the manuscript. This work was supported by NIH grants CA33297 (A.V.), CA18662 (H.T.A.), CA17575 (D.E.H.) and CA28608 (N.H.). I.B.R. is the recipient of a post-doctoral fellowship from the American Cancer Society.

Bone marrow cells give rise to distinct cell clones within the thymus

Sophie Ezine, Irving L. Weissman & Robert V. Rouse

Laboratory of Experimental Oncology, Department of Pathology, Stanford University School of Medicine, Stanford, California 94305, USA

The thymus is the major, if not the sole site of maturation of T lymphocytes from their haematopoietic precursors[1]. During embryonic life (at a few well-defined intervals, at least in birds[2]) the thymus receives thymus-homing haematopoietic precursors that give rise to antigen-specific functional T lymphocytes[3–10]. Although the number and thymic location of distinct T-cell lineages destined to form the peripheral T-cell pool are not yet well defined, at least two independent pathways have been proposed. First, thymic subcapsular lymphoblasts divide and differentiate to give rise to small deep cortical thymic lymphocytes, medullary lymphocytes[11,12] and thymus emigrants (I.W., unpublished data) and second, the medulla contains an independent self-renewing population that contains the precursors of the peripheral T-cell pool[13]. Following irradiation the thymus may be repopulated by injected haematopoietic cells presumably related to the thymus-homing haematopoietic cells of the embryo[14,15]. Here we have reconstituted irradiated mice with limiting numbers of bone marrow cells from Thy-1 congeneic donors and have found distinct clones of cells within the thymus. The pattern of reconstitution by the precursor cells indicates that two independent thymus lineages exist: cortex plus medulla, and medulla alone.

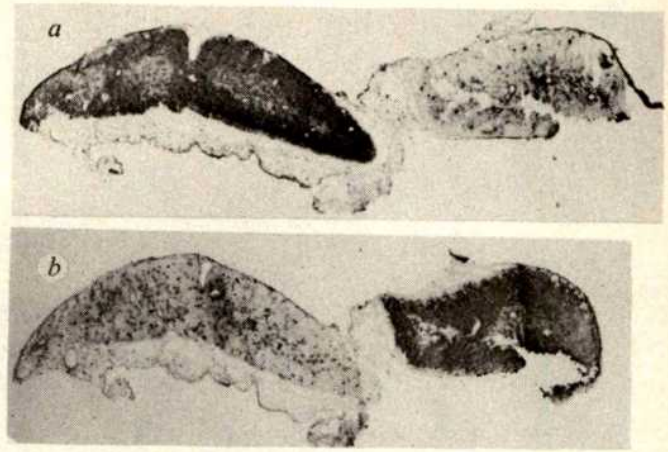

Fig. 1 Thymus from an irradiated (850 rad) C57BL/6$H\text{-}2^k$ (Thy-1.2) mouse 1 month post-reconstitution with 5×10^6 bone marrow cells (twice treated with anti-Thy-1 + complement) from a C57BL/KaThy-1.1 ($H\text{-}2^b$) donor stained with *a*, anti-Thy-1.1 and *b*, anti-Thy-1.2. Immunoperoxidase stains of frozen sections[20] were performed with monoclonal rat anti-Thy-1.2 (clone 30-H12, Becton-Dickinson) and biotin conjugated monoclonal mouse anti-Thy-1.1 (clone 19xE5) (gift of R. Nowinski) followed by rabbit anti-rat and peroxidase conjugated swine anti-rabbit (Dako) or peroxidase conjugated avidin (Vector). The left lobe is virtually entirely repopulated by donor type cells and the right lobe is virtually entirely repopulated by host type cells. Only infrequent individual cells of the opposite type are seen in each lobe.

While analysing thymic repopulation in allogeneic bone marrow chimaeras we noted one chimaera[16]—in which the allogeneic bone marrow cells differed from the host for both major histocompatibility complex (MHC) encoded antigens and Thy-1 type—that showed one lobe of the thymus entirely reconstituted with donor type Thy-1 cells, whereas the other lobe was entirely reconstituted with host-type Thy-1 cells (Fig. 1). Wallis *et al.*[17] observed that in radiation chimaeras only a few chromosomally-marked cells are needed to reconstitute an entire thymus and we were concerned that a selection process based on MHC allogenicity could have accounted for this remarkable reconstitution of two thymic lobes by two distinct stem cells. Therefore, we undertook a series of studies in which mixtures of bone marrow cells depleted of mature Thy-1^+ cells (by extensive anti-Thy-1 + complement treatment) were injected intravenously into lethally irradiated Thy-1 congeneic hosts. Mice were reconstituted with bone marrow cells varying in the ratio of donor to host Thy-1 type from 1:10 to 1:100, and thymuses were taken from hosts 2–10 weeks post-irradiation. The patterns of thymocyte repopulation were examined immunohistochemically on frozen sections using monoclonal anti-Thy-1.1 and anti-Thy-1.2 antibodies.

We have examined 80 thymus lobes among which 35 contained either extremely rare or no donor cells. The following analysis is based on the 45 lobes containing significant repopulation by donor type cells. In 5 of these lobes, discrete confluent foci of the minority population in the bone marrow mixture (the donor type) were present and ranged in size from 20 to 30 cells

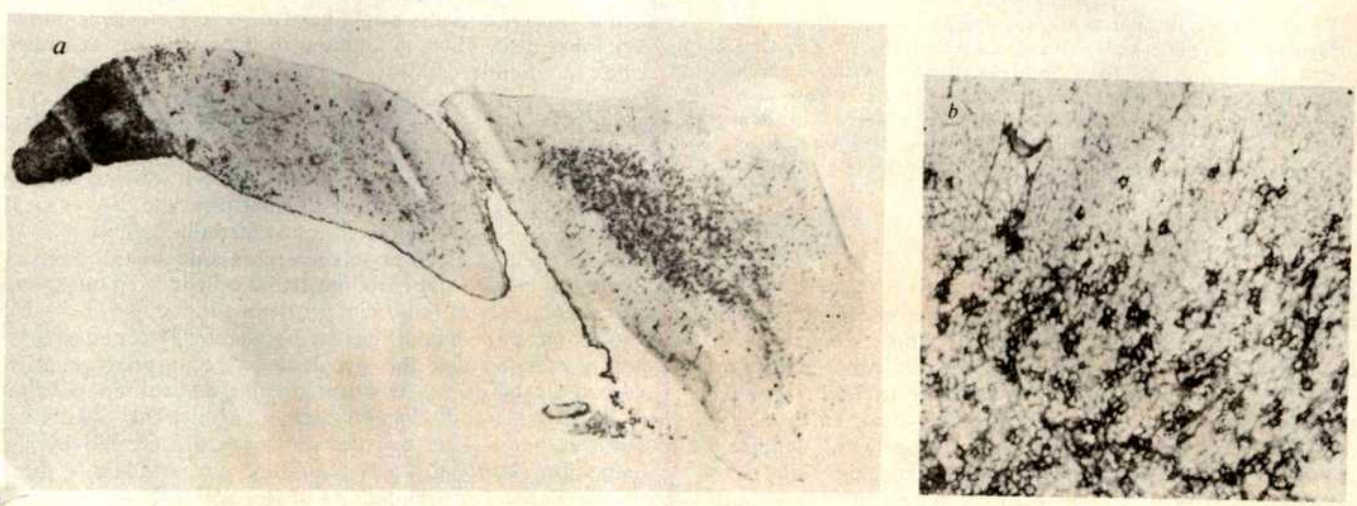

Fig. 2 Thymus of an irradiated (850 rad) C57BL/KaThy-1.1 mouse reconstituted with a mixture of anti-Thy-1 + complement treated bone marrow cells from identical and congenic (C57BL/Ka, Thy-1.2) mice, total dose 2.5×10^6 cells, Thy-1.2:Thy-1.1 (1:50), 4 weeks after reconstitution and stained here with anti-Thy-1.2 as described in Fig. 1. In this experiment and all others less than 1% of the remaining viable cells were Thy-1 positive. *a*, The left lobe contains a discrete confluent focus of donor type cells while the right lobe contains large numbers of donor type cells in the medulla with only very rare cells in the cortex. *b*, High-power view of cortex (top edge) and medulla (bottom) of right lobe, illustrating donor type (Thy-1.2) cells only in medulla.

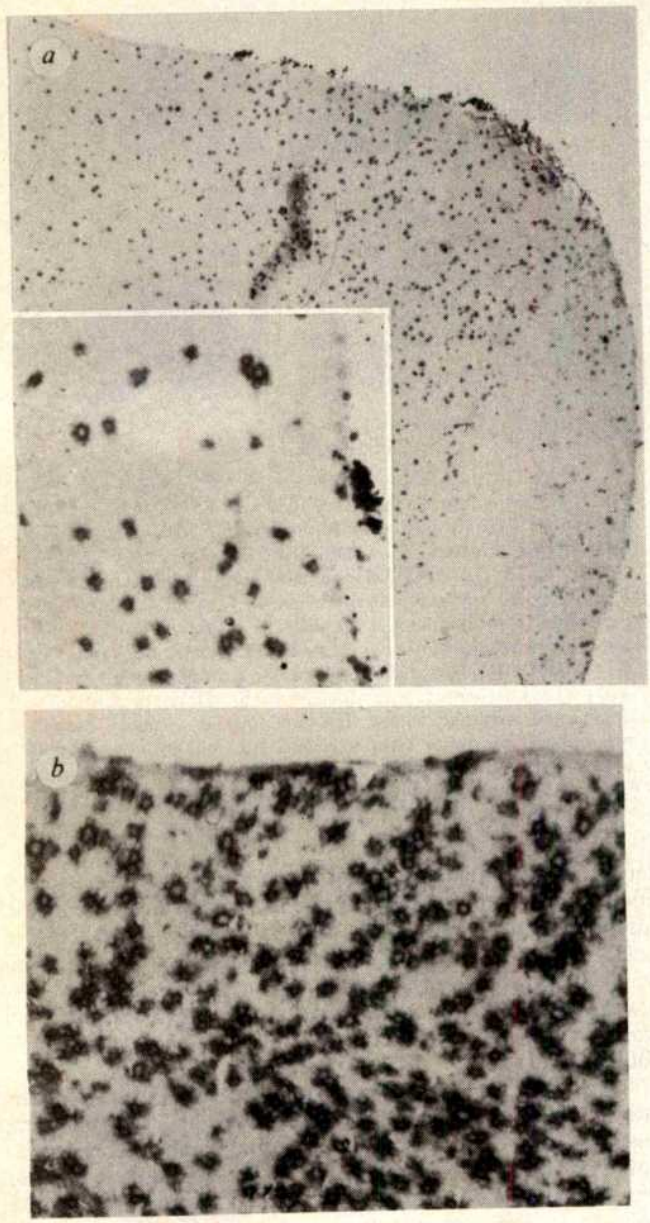

Fig. 3 Thymus of same mouse strain and reconstituted with the same total number of cells as Fig. 2, but with *a*, Thy-1.2:Thy-1.1 = 1:10, stained with anti-Thy-1.2 6 weeks after reconstitution and *b*, Thy-1.2:Thy-1.1 = 1:100, stained with anti-Thy-1.2 28 days after reconstitution. In *a* focal repopulation with scattered individual cells can be seen (cortex in lower right is negative). Inset: high-power view of individual cells. *b*, Scattered clusters of cells.

in diameter to areas of repopulation which occupied half a thymic lobe. Such foci always involved the subcapsular region, and larger foci extended to the cortico-medullary junction (Fig. 2*a*); in such cases, donor type cells were always present in the underlying medulla. In 2 of 45 thymus lobes a striking repopulation was seen: a complete reconstitution of an entire thymic lobe by the minority repopulation of donor Thy-1 type cells (1:10 ratio, 2.5×10^6 total cells transferred), with only infrequent scattered individual cells of the host Thy-1 type. This type of reconstitution is identical to that seen in the allochimaeric thymus shown in Fig. 1. The data in Figs 1 and 2 demonstrate that one or a few cells can reconstitute an entire thymic lobe.

The most frequently observed pattern of donor type cells was that of focal accumulations of scattered cells present either individually (19 of 45 thymus lobes), or as a cluster of 2–5 cells each (13 of 45 thymus lobes), generally present in both the outer and the deep cortex (Fig. 3); the medulla underlying areas of cortex containing these scattered cells also contained scattered donor type cells. We interpret these clusters and individual cells as representing the progeny of thymus homing cells of more limited proliferation potential, and perhaps of greater frequency than the fully reconstitutive thymic repopulating cells.

These various repopulation patterns could be seen as early as 13 days and as late as 10 weeks following irradiation and reconstitution. Thus we believe that we are seeing fundamental types of thymic reconstitution by incoming bone marrow cell types, and not a chance observation.

While it is possible that reconstitution occurred from multiple Thy-1 identical precursors by Thy-1 specific recruitment, preliminary experiments using bone marrow cells expressing Lyt-1 allotypic differentiation antigens also resulted in focal repopulations in three independent cases out of eight tested. We therefore conclude that these foci do not result from a Thy-1-allotype-specific congregation of cells but derive from single precursor cells.

A striking and entirely unexpected type of reconstitution occurred in 6 of the 45 thymus lobes examined: donor type thymocytes were identified only in the medulla (Fig. 2*a*, lobe on the right, and Fig. 2*b*). Multiple levels cut through these thymuses failed to demonstrate more than rare individual donor type thymocytes in the cortex. The donor type thymocytes comprised 40–60% of medullary thymocytes, and were scattered individually without clustering or localization to any specific region of the medulla. Host type thymus lymphocytes, present in abundant numbers in the cortex of these thymus lobes, made up the remainder of medullary thymic lymphocytes. While it is conceivable that medullary reconstitution could derive from recirculating mature T cells, the presence of medullary reconstitution in only one of two lobes (Fig. 2*a*) is not consistent with this pattern. All six lobes which exhibited this pattern of medullary reconstitution were from mice which had received relatively low absolute numbers of donor type bone marrow cells (1:50 ratio, 2.5×10^6 total cells transferred), and, like most thymuses, were examined 4 weeks after the transfer. Repopulation restricted to the medulla can be discerned only if there is no cortical repopulation in the same lobe by donor cells; its occurrence at higher doses of bone marrow cells may be obscured by concomitant cortical repopulations.

These findings support the proposition that the medulla may contain a separate lineage of cells which are capable of self-renewal over long intervals[13,18,19]. However, it is not possible to rule out their derivation from cortical precursors although such cortical precursors would have to be very transient and/or very infrequent. Thus, in addition to the previously described cortex to medulla pathways of development of medullary thymocytes[11,12], there could be a separate lineage of medullary cells which does not involve substantial contribution from cortical precursors in mice. Such a pathway has been reported in birds[18]. It is not clear from these experiments if the cell which is capable of repopulating the medulla is different from the cell which is capable of repopulating the cortex to medulla pathway.

The peripheral T-cell population represents the full diversity of antigen-specific and MHC-restricted cells in each functional subclass, and it is important to define the stage of thymic maturation at which such diversity is generated. We[1] and others[17] have postulated that this event could occur pre-thymically. However, experiments demonstrating oligoclonal repopulation of the thymus would seem to speak out against that possibility. However, most bone marrow chimaeras are created by the injection of 2×10^6 to 2×10^7 cells; by our calculations, these inocula would contain hundreds of clonogenic thymus-repopulation cells. Whether the full diversity of the T-cell repertoire, as well as its commitment to different functional lines, could be realized pre-thymically even with a few hundred clones is still in question.

Accumulation of a heat shock-like protein during differentiation of human erythroid cell line K562

Mandaleshwar K. Singh & John Yu

Department of Molecular Biology, Research Institute of Scripps Clinic, La Jolla, California 92037, USA

The human erythroid cell line K562 provides a model system for studying erythroid differentiation and eukaryotic gene regulation. These cells express glycophorin A, spectrin and i antigen[1–4]. They accumulate embryonic and fetal haemoglobins on induction of erythroid differentiation with haemin, sodium butyrate or hydroxyurea[5,6]. In the present study, the protein composition of K562 cells during haemin-mediated induction of erythroid maturation was analysed by two-dimensional gel electrophoresis. Under conditions in which haemin did not affect cell viability and proliferation[7], a protein of ~70,000 molecular weight (MW) accumulated in the differentiated K562 cells. The accumulation appears to be due to an increase in the rate of RNA synthesis for this protein. The protein is related in sequence to a 70,000-MW heat shock protein. An antigenically related protein was also demonstrated in human bone marrow and accumulates at particular stages of human erythroid maturation.

The total protein composition and rates of protein synthesis before and after haemin induction of K562 cells were examined (Fig. 1). After 40 h of incubation with 25 μM haemin, approximately 95% of the K562 cells stained positively with benzidine. The two-dimensional electrophoretic analyses (Fig. 1) indicate that a 70,000-MW protein(s) (p70) accumulated in the haemin-induced sample (*b*), but not in the uninduced cells (*a*). Most other proteins were similar in both induced and uninduced cells. The similarity between isoelectric variants of p70 was demonstrated by two-dimensional peptide mapping analysis (data not shown). Figure 1*d*, *e* also shows that when cells were labelled with ^{35}S-methionine after induction with haemin, an enhanced labelling of the p70 occurred. We also used a cell-free system containing mRNA from haemin-treated K562 cells to show that the p70 protein represented a predominant peptide product which was not detectable among the translation products of control mRNA from untreated cells (Fig. 2). Therefore, the induction of this protein seems to be due to an accumulation of its mRNA over other cellular mRNAs.

As some heat shock stress proteins have been recently assigned a developmental role[8–10], the response of K562 cells to heat shock was investigated. Figure 1*c* shows that after exposure to 43 °C, K562 cells accumulated a series of 70,000-MW heat shock protein(s). In addition to the similarity of molecular weight and appearance in a two-dimensional gel, the heat shock p70 and the haemin-induced p70 show similarity in sequence as deduced from their similar peptide mappings described in Fig. 3 and from the digestion patterns of the two ^{35}S-labelled proteins by *Staphylococcus* protease[11].

An antigenic similarity between haemin-induced p70 and HeLa cell heat shock p70 was discovered by using antiserum to the HeLa cell proteins (given by J. Nevins). Cell extracts from control and haemin-induced K562 cells were separated by SDS-polyacrylamide gel electrophoresis (PAGE) and the proteins electro-blotted to nitrocellulose paper[12]. Using these blots, antiserum against HeLa heat shock p70 reacted with 70,000-MW protein(s) from the K562 cells and these protein(s) were accumulated more than 10-fold in the induced cells compared with uninduced cells (Fig. 4*c*, *d*). The cross-reactive p70 in the haemin-induced K562 constituted approximately 6% of the total Coomassie-stained proteins (Fig. 4*b*). Given the immunological relatedness of haemin p70 to heat shock p70, we used a cDNA clone encoding the heat shock p70 in HeLa cells (a gift from J. Nevins) to assay the transcription rate of nascent RNA synthesis for its related protein. By using an *in vitro* nuclear transcription assay[13], it was estimated that there was a ~5-fold increase in the rate of transcription for p70 protein(s) in haemin-induced cells (data not shown). Therefore, transcriptional stimulation seems to be responsible for the accumulation of mRNA for haemin p70 in the induced K562 cells.

An antigenically cross-reactive protein was detected in extracts of human bone marrow, but not in mature erythrocytes (see Fig. *e*, *f*). Specific immunoprecipitation of a 70,000-MW protein(s) was found (Fig. 4*g*, *h*) when extracts of ^{35}S-labelled bone marrow cells were precipitated with the same antiserum against heat shock p70, but not with control serum. Furthermore, when erythrocytes and late erythroblasts in bone marrow samples were lysed by hypotonic shock[14], the 70,000-MW antigen reactive with anti-heat shock p70 was found only in the lysate and not in the pellet. This indicates that the antigen is present only in these relatively mature and lysable erythroid cells. In addition, when bone marrow cells were fractionated in a Percoll density gradient[15], the ^{35}S-labelled p70 was present in the fraction, containing predominantly erythroblasts. Therefore, human bone marrow cells, probably the late erythroblasts, have protein(s) of molecular weight 70,000 that cross-react with anti-heat shock p70.

As haemin-induced p70 accumulated in the differentiated erythroblasts of both K562 and bone marrow, its induction in K562 cells may reflect a differentiation event, rather than being a general response to stress conditions. The inducer, haemin, is a normal cellular metabolite, important for normal regulation of protein synthesis and erythroid differentiation[16,17]. The induction conditions applied did not affect cellular viability and proliferation[7], and other stress conditions such as glucose starvation did not induce accumulation of the protein in K562 cells (unpublished data). Furthermore, haemin induction of the p70 exhibits tissue specificity, as incubation of HeLa cells with haemin did not result in production of a similar protein (unpublished observation). Recently, other heat shock proteins have been found to have a developmental role. Heat shock proteins 22 and 26 of *Drosophila* are differentially transcribed during normal development[8]. The expression of four small heat shock proteins in *Drosophila* marginal disk is stimulated by ecdysterone hormone[9]. Moreover, several genes in *Drosophila* and yeast, which are related to heat shock p70, but present at different chromosomal loci, are normally expressed during development but not induced by heat shock (the heat shock–cognate genes[10]). The haemin-induced p70 protein may represent a selective activation of gene(s) 'cognate' to the heat shock genes during erythroid maturation and independent of heat shock treatment.

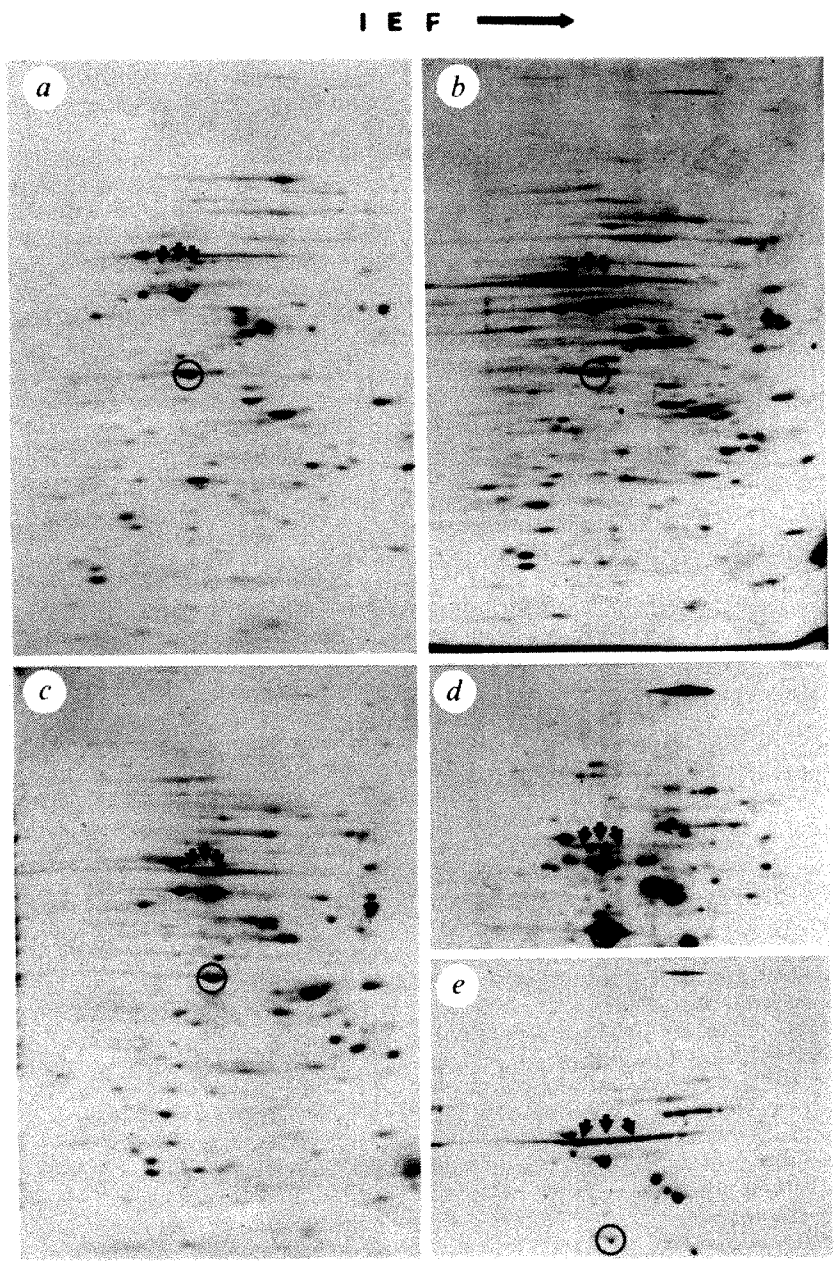

Fig. 1 Protein composition of: *a*, control; *b*, haemin- and *c*, heat shock-induced K562 cells analysed by two-dimensional gel electrophoresis. Arrows indicate the position of the 70,000-MW protein(s) and circles indicate actin. *d*, *e*, Fluorographs of the two-dimensional gels from samples of ^{35}S-labelled control and haemin-induced K562 cell, respectively. The cells were washed with Hank's balanced salt solution and labelled for 30 min in methionine-free RPMI (Gibco) medium containing 5% dialysed fetal calf serum and 50 μCi ml^{-1} ^{35}S-methionine. The fluorograph for haemin-induced cells was underexposed to show the enhanced synthesis of protein(s) indicated by arrows. Only those portions of the fluorographs with molecular weights larger than actin (indicated by circles) are shown.
Methods: K562 cells were grown in minimum essential medium containing 15% fetal calf serum and induced with 25 μM haemin for 40 h. Heat shock treatment included incubation of K562 cells at 43 °C for 1 h. The two-dimensional gel electrophoresis was done according to O'Farrell[18]. Briefly, 10^8 cells were washed with phosphate-buffered saline (PBS) and solubilized in 250 μl of lysis buffer (9.5 M urea, 2% Nonidet P-40, 4% *p*H 5–7 ampholine, 1% *p*H 3–10 ampholine and 5% 2-mercaptoethanol) and 50-μl aliquots were applied to isoelectric focusing (IEF) gel containing the same ampholine concentrations. SDS-PAGE in the second dimension was carried out on a 7.5–15% acrylamide gradient gel[19]. The gels were stained with Coomassie blue as described elsewhere[20].

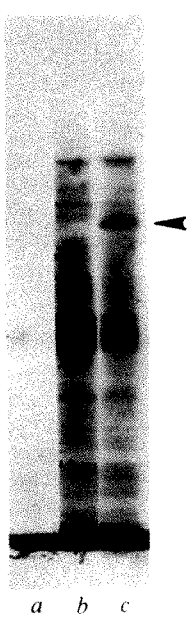

Fig. 2 *In vitro* protein synthesis directed by mRNA isolated from haemin-induced and uninduced K562 cells. RNA was isolated from uninduced K562 cells or cells induced in the presence of 25 μM haemin for 48 h. After washing with PBS, the cells were solubilized in 4 M guanidine thiocyanate and RNA prepared by pelleting through a CsCl gradient as described[21]. The poly(A)-containing RNA was isolated by oligo(dT)–cellulose chromatography, translated in a rabbit reticulocyte lysate system and analysed by electrophoresis and fluorography. The sources of mRNA used in the *in vitro* translation are as follows: *a*, no mRNA; *b*, uninduced K562 cells; *c*, haemin-induced K562 cells.

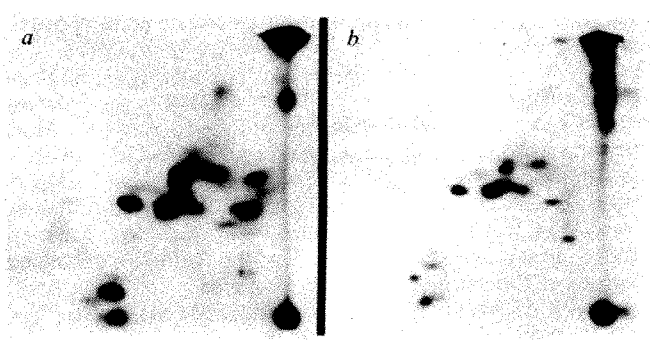

Fig. 3 Comparison of ^{125}I-labelled tryptic peptides of the haemin(*a*) and heat shock(*b*)-induced p70 of K562 cells. Gel slices were excised from the two-dimensional gel in Fig. 1*b* and *c* containing the p70 proteins and radioiodinated as described[22]. After extensive washings, the proteins were cleaved with 5 μg trypsin. Peptide analysis was performed by loading approximately 1 × 10^6 c.p.m. onto each cellulose-coated TLC plate. The samples were electrophoresed and chromatographed as described elsewhere[22]. Finally, the plates were dried and analysed by autoradiography.

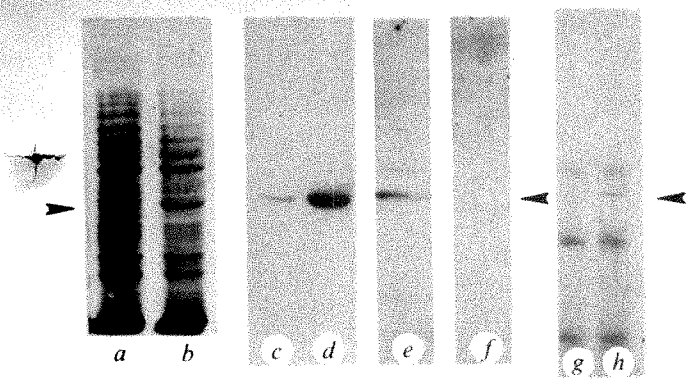

Fig. 4 Cross-reaction of a 70,000-MW protein in K562 cells and human bone marrow with antiserum against HeLa cell heat shock p70. K562 cells were induced with haemin as described in Fig. 1 legend. Equivalent aliquots of control (*a*, *c*) and induced (*b*, *d*) cells were washed extensively, solubilized by boiling in SDS-lysis buffer (62.5 mM Tris-HCl *p*H 6.8, 2% SDS, 10% glycerol, 5% β-mercaptoethanol and 0.001% pyronin Y), then analysed on a 7.5% acrylamide gel. Samples for *e* and *f* contained approximately 50 μg of SDS-solubilized proteins from human bone marrow and adult erythrocytes, respectively. After electrophoresis, lanes *a* and *b* were stained with Coomassie blue and lanes *c*–*f* were electroblotted to nitrocellulose paper[11] and probed sequentially with antiserum against HeLa cell heat shock p70 and ^{125}I-labelled protein A. In other experiments, equal aliquots of the same cell extracts from the ^{35}S-labelled human bone marrow cells were immunoprecipitated (*g*, with control serum; *h*, with antiserum against heat shock p70). They were then electrophoresed in a 7.5–15% gradient gel containing 1% SDS. Arrows indicate the position corresponding to the 70,000-MW protein.

Glycoprotein C of herpes simplex virus 1 acts as a receptor for the C3b complement component on infected cells

Harvey M. Friedman*, Gary H. Cohen†, Roselyn J. Eisenberg‡, Cynthia A. Seidel* & Douglas B. Cines§

* The Joseph Stokes Jr Research Institute, The Children's Hospital of Philadelphia, 34th Street, Philadelphia, Pennsylvania 19104, USA
† School of Dentistry, ‡ School of Veterinary Medicine and
§ Department of Medicine, School of Medicine, University of Pennsylvania, Philadelphia, Pennsylvania 19104, USA

Receptors for the Fc portion of immunoglobulins or for the third component of complement (C3) are present on a variety of circulating and fixed tissue cells including granulocytes, monocytes, lymphocytes and glomerular epithelial cells[1–4]. Cells which lack Fc receptors may express them after infection by herpes simplex virus (HSV)-1, HSV-2, cytomegalovirus or varicella zoster virus[5–8]. We recently reported that infection by HSV-1 induces both Fc and C3 receptors on human endothelial cells[9]. Glycoprotein E of HSV-1 has been shown to function as an Fc receptor[10]. We now demonstrate that glycoprotein C (gC) of HSV-1 functions as a C3b receptor. This receptor appears following HSV-1, but not HSV-2, infection. Detection of the C3b receptor is blocked by monoclonal antibodies to glycoprotein C (gC) of HSV-1, but not by monoclonal antibodies to other HSV-1 glycoproteins. In addition, the MP mutant of HSV-1, which lacks gC, fails to express a C3b receptor. These results assign a new function of gC of HSV-1 and demonstrate potentially important differences between HSV-1 and HSV-2 glycoproteins.

Figure 1*a* shows the binding of C3b-coated erythrocytes to HSV-1 infected endothelial cells by light microscopy. Rosettes (>4 erythrocytes per endothelial cell) were found with 70% of infected endothelial cells: no rosettes formed around uninfected cells, nor around infected cells incubated with IgM- coated erythrocytes or with erythrocytes coated with complement components (C142) but not C3 (Fig. 1*b*). The specificity of the C3b-coated erythrocytes for C3b receptors was demonstrated by the ability of purified C3b fragments totally to inhibit rosetting. In contrast, purified C3 failed to block rosettes.

A second assay system was used to detect C3 receptors on infected endothelial cells (Fig. 1*c*). Complement-coated bacteria were prepared as indicator cells by incubating *Salmonella typhi* with antibody-negative fresh human serum[11]. Extensive attachment of bacteria occurred to HSV-1 infected endothelial cells. No attachment occurred to uninfected cells. Similarly no attachment occurred to infected cells when bacteria were incubated with heat-inactivated serum rather than fresh serum as the source of complement.

These results suggested that the receptor might be a viral glycoprotein. To test this, endothelial cells were infected with HSV-1 in the presence of tunicamycin to inhibit glycoprotein expression[12,13]. 3 μg ml^{-1} of tunicamycin added 1 h post-infection decreased from 70% to 5% the number of infected cells showing rosettes of C3b-coated erythrocytes at 24 h. Figure 2*a* shows the results expressed as the % binding of ^{51}Cr-labelled, C3b-coated erythrocytes.

Experiments were performed with several different HSV-1 and HSV-2 strains. Four low passage clinical isolates of HSV-1 all induced C3b receptors (Fig. 2*b*). Light microscopy revealed rosettes of C3b coated erthrocytes around 70–75% of the infected endothelial cells following infection with each HSV − 1 strain but no rosettes were found with clinical isolates of HSV-2 by either the ^{51}Cr-erythrocyte binding assay (Fig. 2*c*) or microscopic examination. All HSV-1 and HSV-2 strains induced IgG Fc receptors as measured by binding and rosetting of IgG-coated, ^{51}Cr-labelled erythrocytes (results not shown).

Glycoproteins A/B, D and E of HSV-1 have antigenic determinants in common with the equivalent glycoproteins of HSV-2 but gC of HSV-1 is predominantly type-specific[14–16]. To examine whether gC acts as the C3b receptor, we looked for expression of the receptor in cells infected with the MP mutant of HSV-1, which fails to express gC[17]. No C3b receptor activity was detected in these cells, as measured by the ^{51}Cr-erythrocyte binding assay (Fig. 2*c*) or by rosetting. In contrast, expression of Fc receptors by the MP mutant was normal, as detected both by the ^{51}Cr-binding assay and by rosetting of IgG-coated erythrocytes (results not shown).

To define further the role of gC of HSV-1 as a C3b receptor, blocking assays were performed using a series of anti-herpes antibodies as described in the legend to Fig. 3. When HSV-1 infected endothelial cells were incubated with antiserum against HSV-1 envelope antigens[15], binding of ^{51}Cr-labelled, C3b-coated erythrocytes to infected cells was markedly reduced (Fig. 3). Monoclonal antibodies to gA/B, gD and gE had no effect on binding of these erythrocytes when antibodies were tested at a 1 : 10 dilution (Fig. 3) or undiluted (results not shown). In contrast, monoclonal antibody to gC reduced markedly the binding of ^{51}Cr-labelled, C3b-coated erythrocytes. This reduction

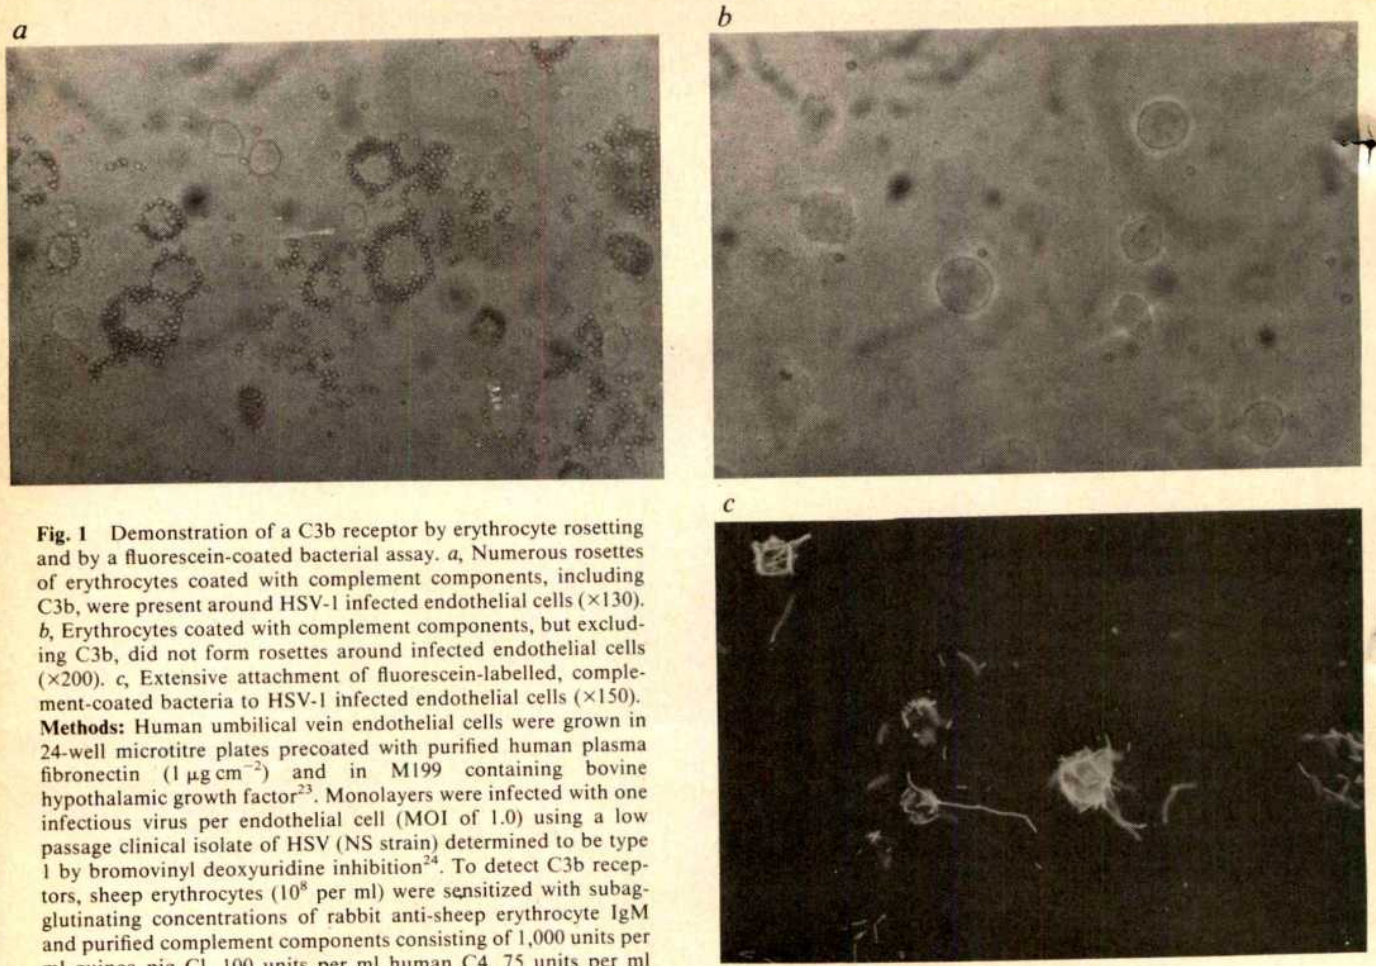

Fig. 1 Demonstration of a C3b receptor by erythrocyte rosetting and by a fluorescein-coated bacterial assay. *a*, Numerous rosettes of erythrocytes coated with complement components, including C3b, were present around HSV-1 infected endothelial cells (×130). *b*, Erythrocytes coated with complement components, but excluding C3b, did not form rosettes around infected endothelial cells (×200). *c*, Extensive attachment of fluorescein-labelled, complement-coated bacteria to HSV-1 infected endothelial cells (×150). **Methods:** Human umbilical vein endothelial cells were grown in 24-well microtitre plates precoated with purified human plasma fibronectin (1 $\mu g\,cm^{-2}$) and in M199 containing bovine hypothalamic growth factor[23]. Monolayers were infected with one infectious virus per endothelial cell (MOI of 1.0) using a low passage clinical isolate of HSV (NS strain) determined to be type 1 by bromovinyl deoxyuridine inhibition[24]. To detect C3b receptors, sheep erythrocytes (10^8 per ml) were sensitized with subagglutinating concentrations of rabbit anti-sheep erythrocyte IgM and purified complement components consisting of 1,000 units per ml guinea pig C1, 100 units per ml human C4, 75 units per ml guinea pig C2 and 100 units per ml human C3 (Cordis Labs)[9,25]. Sheep erythrocytes were also prepared as above but C3 was omitted. Sheep erythrocytes without complement components were used in some experiments and prepared as described previously[9]. Erythrocyte rosetting assays[9] were performed 24 h post-infection using a ratio of 100 erythrocytes per endothelial cell. Heat-killed *Salmonella typhi* were fluoresceinated and incubated for 15 min with human serum as a source of complement from a donor lacking antibodies to *Salmonella*.[11] 24 h after HSV-1 infection, endothelial cells were removed by scraping and were incubated for 30 min with complement-coated bacteria.

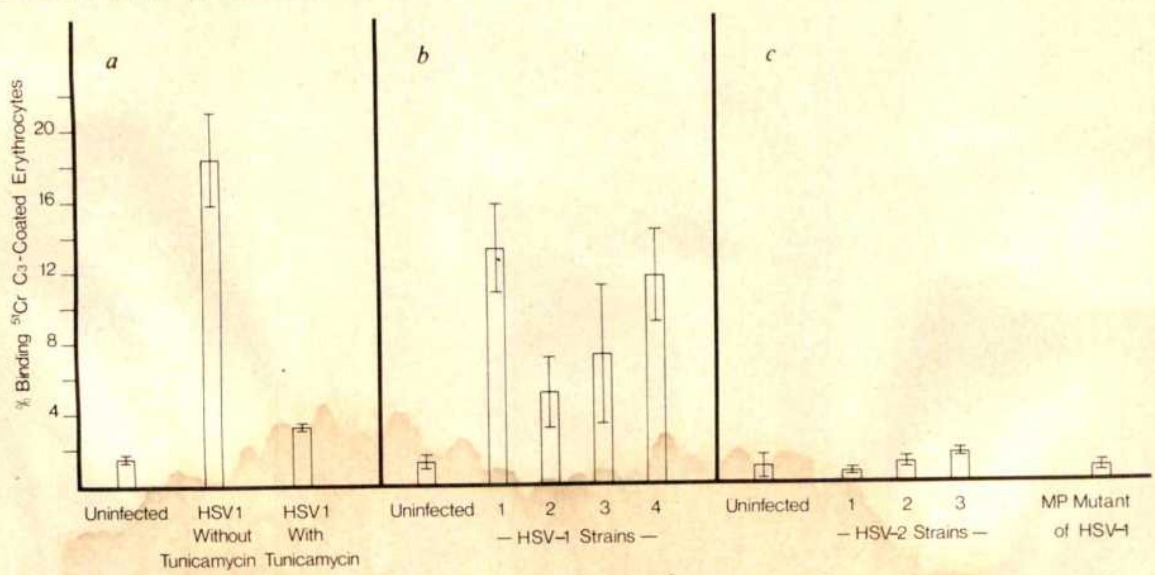

Fig. 2 Binding of coated erythrocytes to infected endothelial cells. *a*, Endothelial cells were infected with HSV 1 (NS strain) at an MOI of 1.0. One hour after infection, tunicamycin, 3 $\mu g\,ml^{-1}$, was added to some cultures and 24 h after infection sheep erythrocytes coated with IgM and C1, 2, 3, 4 were added to detect C3b receptors. *b*, 24 h after infection of endothelial cells at an MOI of 1.0 with 4 HSV-1 low passage, clinical isolates, sheep erythrocytes coated as above were added to detect the C3b receptor. *c*, Three low passage HSV-2 strains and the MP mutant of HSV-1 were used at an MOI of 1.0 to infect endothelial cells. 24 h later, sheep erythrocytes coated as above were added to detect C3b receptors. At this time cytopathic changes were present in 100% of cells and 10^6–10^7 $TCID_{50}$ infectious viruses were being produced per culture well. Erythrocytes were radiolabelled with 100 μCi ^{51}Cr (Na_2CrO_4,) per 10^9 cells and prepared as described in the legend to Fig. 1. Binding assays were performed as described previously[9] and expressed as the ratio of ^{51}Cr-labelled erythrocytes bound to the monolayer to the total ^{51}Cr-labelled erythrocytes added to the monolayer ×100%. Each bar is the mean of two experiments.

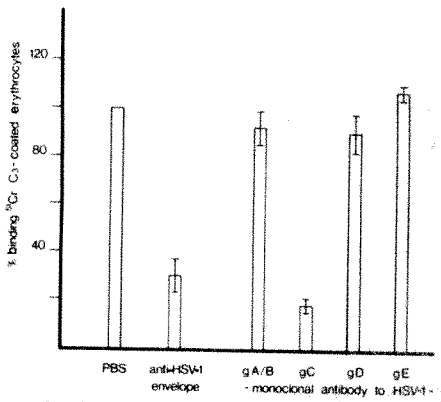

Fig. 3 Herpes antisera block the binding of C3b-coated erythrocytes to HSV-1 infected endothelial cells. Endothelial cells were infected with HSV-1 (NS strain) at an MOI 0f 1.0. 24 h later the monolayers were incubated for 30 min with 0.1 ml of either phosphate-buffered saline (PBS), antisera to HSV-1 envelope glycoproteins, or monoclonal antibodies to HSV-1 gA/B, gC, gD or gE. Unbound antiserum was removed by washing and ^{51}Cr-labelled erythrocytes, coated as described in the legend to Fig. 1, were added to detect HSV-1 induced C3b receptors. Binding of erythrocytes to infected cells in the presence of PBS was assigned a value of 100%. To calculate the effect of immune serum on blocking erythrocyte binding, the following formula was used:

$$\frac{^{51}\text{Cr-erythrocyte binding in presence of immune serum}}{^{51}\text{Cr-erythrocyte binding in presence of PBS}} \times 100\%$$

Monoclonal IgG antibodies to HSV-1, gA/B (24S), gC (5S, 17S, 19S, 27S) and gD (1S, HD1) were kindly provided by Drs B. Hamper, M. Zweig and L. Pereira. The specificity, neutralization titre, immunofluorescence activity and immunoglobulin subtypes of these monoclonal antibodies have been described elsewhere[26,27]. Additional monoclonal antibodies were prepared by the method of Holland *et al.*[14] against the low passage clinical isolate of HSV-1 (NS strain) used in these studies. Characterization of these antibodies as IgG2a anti-HSV-1 gC (1C8), gD (1D3) and gE (1E3) will be presented elsewhere (H.M.F. *et al.*, manuscript in preparation). Briefly, each of the monoclonal antibodies has neutralizing activity against HSV-1; the 1C8 antibody, however, requires complement for viral neutralization. The specificity of the monoclonal antibodies was demonstrated by radioimmunoprecipitation[15] and SDS-polyacrylamide gel analysis of cytoplasmic extracts[28] prepared from HSV-1 infected Hep-2 cells labelled with ^{35}S-methionine 5–10 h post-infection. Each monoclonal antibody immunoprecipitated proteins corresponding in size to those published for precursor and processed forms of specific HSV glycoproteins[10,28,29]. These were as follows: 1C8 anti-gC, 130,000 molecular weight (MW) and 105,000 MW; 1D3 anti-gD, 60,000 MW and 53,000 MW; 1E3 anti-gE, 80,000 MW and 68,000 MW. To block the binding of C3b-coated erythrocytes, a 1:10 dilution of ascites fluid was used. To demonstrate that binding to surface proteins occurs at this concentration, immunofluorescence studies were performed on unfixed HSV-1 infected and uninfected endothelial cells. The end-point titre was calculated as the highest dilution of antibody producing intense fluorescence on infected cells. The fluorescent antibody titres were as follows: anti-gB: 24S, 1:10; anti-gC: 17S, 1:1,000, 1C8, 1:1,000; anti-gD: HD1, 1:1,000, 1D3, 1:1,000; anti-gE: 1E3, 1:10. Each bar is the mean of two experiments except for the gC and gD monoclonal antibody experiments which are the mean of nine experiments.

occurred with each of the five anti-gC monoclonal antibodies examined at a 1:10 dilution (Fig. 3) and at a titre of 1:500 for the one anti-gC monoclonal antibody which was tested in serial dilutions (results not shown).

Anti-gC ascites (1C8) was purified by ammonium sulphate precipitation and DEAE–cellulose chromatography[18]. Purified IgG antibody (8.6 mg ml^{-1}) totally inhibited C3b–erythrocyte binding at a titre $\geq$1:1,000. None of the anti-gC monoclonal antibodies, including purified 1C8 IgG, blocked binding of IgG-coated erythrocytes to the HSV-1 Fc receptor. The anti-gE monoclonal antibody blocked binding of IgC-coated erythrocytes to Fc receptors but had no effect on binding of C3b-coated erythrocytes to the C3 receptor. All these results were confirmed by rosettes, viewed under light microscopy.

These results indicate that gC of HSV-1, either alone or in combination with endothelial cell proteins, serves as a C3b receptor. Receptors for four different cleavage products of C3 have been described on haematopoetic cells, including receptors for C3b, C3b-β1H, C3bi and C3d[4]. Whether any of these other C3 receptors are present on HSV-1 infected cells remains to be determined.

C3b receptors may serve as binding sites for complement-containing antigen–antibody complexes on certain fixed tissue cells and circulating blood cells[19,20]. If the C3b receptors induced by HSV-1 function in a similar manner, they may bind these complement-containing complexes to infected endothelial cells leading to vessel wall injury. Furthermore, C3b receptors on erythrocytes have recently been shown to inhibit activation of both the classical and alternative complement pathways[21,22]. If the viral induced C3b receptor also inhibits complement activation, the receptor may reduce the efficiency with which antibody and complement lyse infected cells but further studies are required to determine the importance of this glycoprotein in the pathogenesis of HSV-1 infection.

This work was supported by NIH grants HL 28220, HL 24914, DE 02623 and AI 18289. D.B.C. is the recipient of NIH Research Career Development Award K04-HL 00956. We thank Dr M. Berger for providing purified C3b, Jeffrey Hastings, Jayneann Wolfe, Deborah Long and Manuel Ponce de Leon for technical assistance and Claire Beckmann for preparing the manuscript.

Ultrabithorax mutations map to distant sites within the bithorax complex of *Drosophila*

Michael Akam, Helen Moore & Angela Cox*

Department of Genetics, University of Cambridge, Downing Street, Cambridge CB2 3EH, UK

Chromosome breaks throughout a 70-kilobase (kb) region of the *Drosophila* bithorax complex (BX-C) result in the homoeotic *Ultrabithorax* (*Ubx*) mutations[1]. These cause the third thoracic and first abdominal segments of the *Drosophila* embryo to develop structures normally characteristic of the first and second thoracic segments[2–6]. We show here by genetic mapping that apparent point mutations with *Ubx* phenotypes are located at both ends of this 70-kb region. Mutations located at either end of the *Ubx* unit have indistinguishable phenotypes, suggesting that both classes inactivate most or all wild-type, *Ubx*$^+$, functions. This observation supports the suggestion[1] that *Ubx* mutations directly inactivate a product encoded by 5′ and 3′ exons of a long transcription unit.

Three *Ubx* mutations have previously been mapped by genetic recombination. All were found to lie at or close to the right-hand end of the *Ubx* unit defined by chromosome rearrangements[1,7,8]. When the DNA of these and other *Ubx* 'point' alleles was examined, four apparently point *Ubx* mutations were found to be associated with small insertions or deletions[1]. Three of these

* Present address: Celltech, 244–250 Bath Road, Slough SL1 4DT, Berkshire, UK.

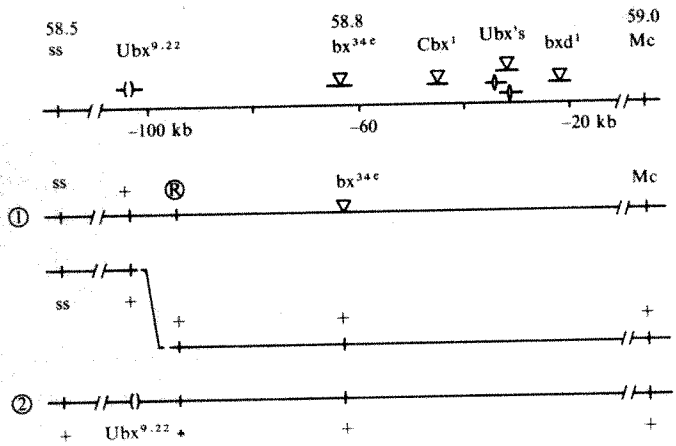

Fig. 1 Location of the $Ubx^{9.22}$ mutation. Top: Map indicating the locations of relevant loci. Numbers at the top of the diagram give the standard genetic map positions of *ss* (*spineless*), bx^{34e} and *Mc* (*Microcephalus*) on the right arm of chromosome III. The DNA scale in kilobases shows the relative locations of insertions (▽) and deletions (-( )-) in BX-C mutant chromosomes. The three *Ubx* lesions located close to −32 kb are Ubx^{1} (insertion), $Ubx^{6.28}$ and Ubx^{849} (deletions)[1]. Bottom: Segregation of the $Ubx^{9.22}$ mutant phenotype. The diagram shows the constitution of parentally derived chromosomes in non-recombinant progeny, and of one diagnostic recombinant. Plus signs indicate wild-type alleles at loci which differ between the parents. R is a restriction site polymorphism characteristic of the bx^{34e} chromosome. All wild-type recombinants lose both the bx^{34e} insertion and the $Ubx^{9.22}$ deletion, and carry the *ss* flanking marker. In the diagnostic recombinant illustrated, recombination must have occurred to the left of −95 kb, as this recombinant chromosome carried restriction sites derived from the $Ubx^{9.22}$ chromosome at the polymorphic site. From the phenotype of these recombinants in *trans* with bx^{34e} it remains possible that two separate mutations are responsible for the phenotype of the $Ubx^{9.22}$ chromosome—a *bx* mutation located to the left of bx^{34e} and a *bxd* mutation located to the right. To eliminate this possibility, bx^{+} chromosomes from each recombinant were established in stock and examined as homozygotes, and in *trans* with a range of bithorax complex mutations, including the deficiencies *Df Ubx 109* or *Df Ubx P2* (ref. 4). In no case did these combinations reveal additional BX-C mutations remaining on the recombinant chromosomes. Thus, no DNA lesion to the right of −95 kb contributes to the phenotype of the $Ubx^{9.22}$ chromosome.

lesions were located within a short (2 kb) target at the extreme right-hand end of the *Ubx* unit, within the region indicated by the genetic mapping. In the fourth case the only detectable lesion on the mutant chromosome was a 1.4-kb deletion located 70 kb from this site, at the extreme left end of the *Ubx* unit. The mapping crosses detailed below show that the *Ubx* mutation on this chromosome ($Ubx^{9.22}$) co-segregates with the observed deletion, and must be associated with DNA sequences to the left of coordinate −95 kb on the DNA map (Fig. 1), beyond the loci of *bx* (*bithorax*) and *Cbx* (*Contrabithorax*) mutations.

Table 1 gives the results of mapping crosses with $Ubx^{9.22}$, and with other previously unmapped *Ubx* alleles. Crosses with the $Ubx^{6.28}$ mutation provide appropriate controls; $Ubx^{9.22}$ and $Ubx^{6.28}$ were X-ray-induced in the same experiment, on chromosomes of common origin[9]. In both cases, the mutant chromosome reveals a deletion when compared with the parental chromosome, but whereas the deletion in $Ubx^{9.22}$ lies well to the left of the *bx* locus, that in $Ubx^{6.28}$ lies in the expected target for *Ubx* 'point' mutations, to the right of *bx* and very close to the site of the Ubx^{1} insertion[1] (Fig. 1).

$Ubx^{9.22}$ *and* $Ubx^{6.28}$ recombine with the bx^{34e} mutation at similar frequencies (Table 1). The flanking markers carried by wild-type recombinants indicate that the $Ubx^{6.28}$ mutation maps, as expected, to the right of bx^{34e}. In contrast, wild-type recombinants with $Ubx^{9.22}$ show the reverse segregation of flanking markers, confirming that the *Ubx* mutation maps to the left of bx^{34e}, and suggesting that it results from the observed deletion.

Table 1 Mapping *Ubx* alleles

Ubx allele	Cross type	Chromosomes tested	No. of BX-C^{+} recombinants	Diagnostic flanking markers on recombinant chromosome: *ss* locus	Diagnostic flanking markers on recombinant chromosome: *Mc* locus
9.22	1	10,500	7	*ss*	
9.22	2	10,400	4	*ss*	+
6.28	1	11,600	5	+	
98	2	7,600	4	+	*Mc*
154	2	13,500	4	+	*Mc*
159	2	28,000	4	+	*Mc*
195	2	22,000	0	−	−
847	2	17,000	3	+	*Mc*
849	2	13,600	3	+	*Mc*
859	2	13,000	3	+	*Mc*

Females heterozygous for each *Ubx* mutation, and for a chromosome carrying the bx^{34e} mutation in *cis* with flanking markers (see Fig. 1), were backcrossed to bx^{34e} homozygous males. Non-recombinant progeny are either bx^{34e}/bx^{34e} or bx^{34e}/Ubx. Both of these genotypes result in the partial transformation of the third thoracic segment into a second thoracic segment. Recombination between the bx^{34e} and *Ubx* mutations generates either wild-type (bx^{+} Ubx^{+}) or double mutant (bx^{34e} *Ubx*) chromosomes. The bx^{+} Ubx^{+} haplotype in *trans* with bx^{34e} gives rise to phenotypically wild-type progeny, which we have identified in these crosses. Recombinants carrying the double mutant chromosome (bx^{34e} Ubx/bx^{34e}) can be distinguished from the non-recombinant genotypes only with some difficulty; no attempt was made to identify such individuals in these crosses. The female genotype in crosses of type 1 was: *FMA3, XX/Y, SM1 Cy/+; sbd*^{2} *ss* bx^{34e}*/red sbd Ubx e.* The female genotype in type 2 crosses was *FMA3, XX/Y; +/+; In(3L)P, h sbd*^{2} *ss* bx^{34e} *Mc/sbd Ubx.* The male genotype for all crosses was: *sbd ss* bx^{34e} (ref. 14). $Ubx^{9.22}$ *and* $Ubx^{6.28}$ have been described elsewhere[9]. The remaining *Ubx* alleles were recovered by Lewis after treatment of a *su(Hw)*^{2} *sbd* chromosome with ethyl methane sulphonate; the allele numbers quoted are derived from the Lewis stock numbers. 98, 154, 159 and 195 are derived from Lewis cross 17756.98, 17756.154, 17756.159 and 17756.195; 847, 849 and 859 from cross 18136.147, 18136.149 and 18136.159 respectively. Heterozygous inversions in chromosomes I and II (series 1 crosses), or I and III left (series 2 crosses) were used to increase the frequency of recombination in the right arm of chromosome III. These enhanced recombination by a factor of ~3 (series 1 crosses, *ss*–bx^{34e} = 1.0% recombination) or 2 (series 2 crosses, *ss*–*Mc* = 1.0% recombination). Correcting for this, and for the recovery of only one recombinant class, the observed recombinants correspond to a map distance of ~0.04 from bx^{34e} to $Ubx^{9.22}$. The map distance between bx^{34e} and *Ubx* alleles located to the right (calculated on pooled data for *Ubx*s 6.28, 98, 154, 159, 849 and 859) is ~0.025 map units. The failure to observe recombinants with the Ubx^{195} allele is significant when compared with these pooled data (expected = 5.5; observed = 0; $P < 1\%$).

To define more precisely the limits within which the $Ubx^{9.22}$ allele maps, DNA was prepared from strains homozygous for the recombinant chromosomes, and restriction fragments in the region of the bithorax complex were compared with those present in the $Ubx^{9.22}$ and bx^{34e} stocks. In each of four tested cases, the recombinant chromosome lacked the restriction fragments characteristic of the *gypsy* insertion in bx^{34e} at −63.5 kb and the deleted fragments characteristic of the $Ubx^{9.22}$ chromosome at −104 kb[1] (Fig. 1). In one particularly informative case (Fig. 1), the wild-type recombinant retained restriction fragments characteristic of the $Ubx^{9.22}$ chromosome throughout the region from −30 to −95 kb, indicating that the recombination event occurred within 5 kb of the deletion present in the $Ubx^{9.22}$ chromosome. We conclude that the $Ubx^{9.22}$ chromosome carries no detectable BX-C mutation located to the right of coordinate −95 kb.

Although the $Ubx^{9.22}$ mutation maps 70 kb from the sites of the Ubx^{1} and $Ubx^{6.28}$ mutations, the phenotypes resulting from all three of these mutations are virtually indistinguishable. Each shows the same range of phenotypes when in *trans* with *bx*, *bxd* and *pbx* (*postbithorax*) mutations of the BX-C[9,10]. Homozygotes for each allele die as larvae, and those that survive to the third larval instar show partially developed anterior spiracles in the

third thoracic and first abdominal segments, which are characteristic of *Ubx* homozygotes[4].

Similar mapping crosses were performed with a series of seven other *Ubx* mutations (Table 1). One of these, Ubx^{849}, is associated with a ~110-base pair (bp) deletion in the *Ubx* 5′ target, but the remainder are candidates for true point *Ubx* mutations[1].

Ubx^{849} and five of the six point alleles map clearly to the right of the bx^{34e} mutation. Our data are consistent with the model that all of these alleles map to the same site as $Ubx^{6.28}$, approximately 0.025 map units from bx^{34e}.

Ubx^{195} does not fit this model. We observed no recombinants between this allele and bx^{34e} (see Table 1). Thus, Ubx^{195} is most likely to map at a site closer to the bx^{34e} mutation than these other alleles.

We do not know the precise location of most of the *Ubx* mutations which map to the right of the bx^{34e} locus, but in those three cases where the mutation has been associated with an identified lesion in the DNA, this lesion is located between −31.5 and −32.5 kb[1], suggesting the existence of a localized target for such mutations.

The $Ubx^{9.22}$ mutation identifies a second target for *Ubx* alleles, which must be located to the left of −95 kb. We have not proved that this *Ubx* mutation results specifically from the observed deletion, but the circumstantial evidence strongly suggests that this is so.

DNA sequences located both in the rightward *Ubx* target and in the region removed by the $Ubx^{9.22}$ deletion are present in processed transcripts of the *Ubx* unit (R. Saint and D. Hogness, unpublished results; see also refs 11–13). Taken together with these molecular data, our results support the suggestion[1] that *Ubx* mutations directly affect the expression of a product (or products) encoded by sequences which span the entire 70 kb of the *Ubx* unit.

We thank S. Kerridge, G. Morata and E. B. Lewis for providing the *Ubx* alleles and E. B. Lewis for much advice. Part of this work was carried out by M.A. in the laboratory of David Hogness at Stanford University, during the tenure of a Damon Runyan—Walter Winchell fellowship. Subsequently the project was supported by the MRC.

Xenopus oocytes can secrete bacterial β-lactamase

M. Wiedmann, A. Huth & T. A. Rapoport

Zentralinstitut für Molekularbiologie der Akademie der Wissenschaften der DDR, 1115 Berlin-Buch, Robert-Rössle-Strasse 10, DDR

Most secretory proteins are synthesized as precursor polypeptides carrying N-terminal, hydrophobic sequences which, by means of a signal recognition particle (SRP)[1,3], trigger the membrane transfer of the polypeptide and are subsequently cleaved off. The signal sequences appear to be interchangeable between prokaryotes and eukaryotes[4,5]. In bacteria, secretion only involves the crossing of a membrane[6], whereas in eukaryotes the secretory process can be separated into two distinct phases: translocation across the membrane of the rough endoplasmic reticulum and subsequent intraluminal transport by processes involving vesicle budding and fusion[7]. Since secretory proteins must be distinguished from other soluble proteins destined for various sites in the reticular system, it is conceivable that eukaryotic secretory proteins possess additional markers distinct from the signal peptide to guide the polypeptide after its transfer through the membrane. Proteins are secreted at different rates from a eukaryotic cell[8,34], suggesting a role in intracellular transport for receptors with differing affinities for some topogenic features in secretory proteins. We have tested this possibility by introducing into the lumen of eukaryotic rough endoplasmic reticulum a prokaryotic protein which, by virtue of its origin, had not been adapted to the eukaryotic secretory pathway. We reasoned that secretion of the bacterial protein would indicate that after membrane transfer no topogenic signal(s) and corresponding recognition system(s) are required. We report here that this is indeed the case.

We have chosen the β-lactamase encoded by the *Escherichia coli* plasmid pBR322 as a model for a prokaryotic secretory protein and *Xenopus* oocytes as eukaryotic test cells. β-Lactamase is the major protein secreted into the periplasm of *E. coli* cells carrying pBR322 and inactivates ampicillin, thus conferring on the bacteria resistance to the antibiotic. *Xenopus* oocytes have been shown to be a surrogate system for the study of the secretion of eukaryotic proteins (see ref. 9 for a review) or the incorporation and transport of plasma membrane proteins[10,11]. These cells, when microinjected with foreign mRNA, usually process the translation products in the same manner as the original cell and direct them to the same sites. They would therefore seem suitable for the present purpose.

β-Lactamase-specific mRNA was synthesized *in vitro* using isolated RNA polymerase from *E. coli* and plasmid DNA as template[12]. Capped mRNA was obtained by adding ^{7}mGpppA to the transcription mixture[13]. Capped mRNA appears to be stabilized against the action of 5′-exonucleases (ref. 14, and data not shown) and is also more efficient than uncapped mRNA in eukaryotic translation systems[15].

Translation of the *in vitro* synthesized RNA in the wheat germ cell-free system produced pre-β-lactamase (Fig. 1, lane 1). The *in vitro* transport of the prokaryotic polypeptide across the rough endoplasmic reticulum membrane was then tested. Addition of SRP, prepared from dog pancreas, to the translation assay abolished the synthesis of pre-β-lactamase (Fig. 1, lane 2). The translational arrest was prevented and signal peptide cleavage occurred if KCl-washed rough microsomes (K-RM) were also present during translation (Fig. 1, lane 3). These membranes are devoid of SRP[16] and inactive by themselves (Fig. 1, lane 4). Identification of the β-lactamase was based on the observation that the product processed *in vitro* by the reconstituted translocation system co-migrated with the authentic enzyme in SDS gels (compare Fig. 1, lanes 3 and 7) and that a plasmid (pKT218) lacking the nucleotide sequence coding for amino acid residues 6–181 of pre-β-lactamase[4] yielded a truncated translation product (Fig. 1, lane 5). Furthermore, cleavage with restriction enzymes within the β-lactamase gene prevented the synthesis of pre-β-lactamase after transcription–translation *in vitro*, whereas cleavage of the plasmid DNA outside the gene had no effect (data not shown).

These results are in complete agreement with those of Müller *et al.*[5] and confirm that the prokaryotic signal peptide is recognized by mammalian SRP and is cleaved by the eukaryotic signal peptidase. Removal of the signal peptide of pre-β-lactamase has also be shown previously in yeast cells[17].

As the wheat germ system possesses a capping system[15], it was important to demonstrate the synthesis of pre-β-lactamase in a reticulocyte lysate system in which endogenous capping could not occur (Fig. 1, lane 6), as a precondition for the experiments with *Xenopus* oocytes in which only pre-capped mRNAs are efficiently translated[14,18]. Synthesis was markedly

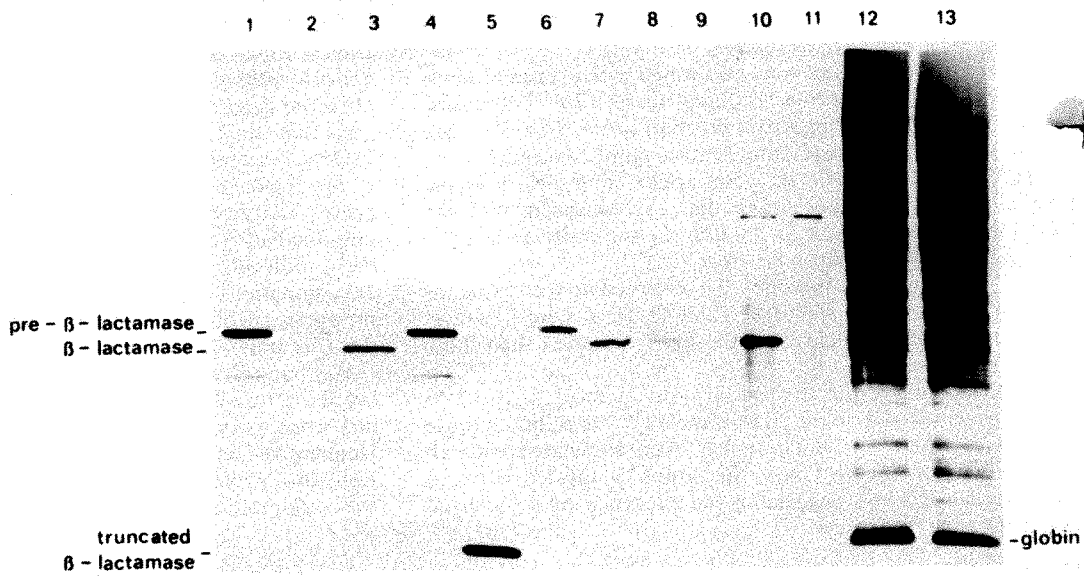

Fig. 1 Translation of *in vitro* synthesized β-lactamase mRNA in cell-free systems and in *Xenopus* oocytes. Lane 1, translation of pBR322-coded RNA in the wheat germ cell-free system. Lane 2, as lane 1 but in the presence of 5 units SRP. Lane 3, as lane 1 but in the presence of 5 units SRP and 0.5 equivalents of K-RM (for definition of units and equivalents see ref. 26). Lane 4, as lane 1 but in the presence of 0.5 equivalents of K-RM. Lane 5, translation of pKT218–coded RNA in the wheat germ system. Lane 6, translation of pBR322-coded RNA in the reticulocyte lysate system. Lane 7, ^{3}H-leucine-labelled periplasmic proteins of *E. coli* cells harbouring pBR322. Lane 8, products in the medium of four oocytes injected with pBR322-coded RNA and globin mRNA and labelled with ^{35}S-methionine (1 mCi ml^{-1}; 1,100 Ci mmol^{-1}) for 12 h (pulse). Lane 9, control to lane 8 with globin mRNA-injected oocytes. Lane 10, as lane 8 but after labelling with ^{35}S-methionine the incubation was continued for 22 h with new medium containing unlabelled methionine (10 mM) (chase). Lane 11, control to lane 10 with globin mRNA-injected oocytes. Lane 12, total products in pulse-chase labelled oocytes injected with pBR322-coded RNA and globin mRNA (the equivalent of 0.05 oocytes was applied). Lane 13, as lane 12 but oocytes only injected with globin mRNA.

Methods: β-Lactamase-specific mRNA was synthesized with isolated *E. coli* RNA polymerase and plasmid DNA as template. The assay contained in 10 μl: 0.34 units *E. coli* RNA polymerase (PL Biochemicals), 3 μg of CsCl gradient-purified pBR322 DNA[27] or pKT218 DNA[4], polyethyleneglycol 6000 (0.16 mg), RNase inhibitor from human placenta[28] (10^{-4} A_{280} units) and ^{7}mGpppA (5 nmol)[13]. Other conditions were as in ref. 5. After transcription the mixture was heated to 60 °C for 5 min. Translation of 2.5 μl transcription mixture in a 12.5-μl assay of a micrococcal nuclease-treated wheat germ system[26] or of a nuclease-treated reticulocyte lysate system[29] was performed in the presence of ^{35}S-methionine (1 mCi ml^{-1}). SRP and K-RM were isolated from dog pancreas according to ref. 16. Proteins of *E. coli* cells carrying the plasmid pBR322 were labelled with ^{3}H-leucine for 60 min and the periplasm was prepared by lysozyme–EDTA treatment[4]. For the oocyte experiments, the *in vitro* synthesized RNA was extracted with phenol–chloroform (1:1), precipitated with ethanol and dissolved in water in 1/4 of the original volume. 3 μl of this solution were mixed with 1 μl of rabbit globin mRNA (1 mg ml^{-1}) and 50 nl were injected into *Xenopus laevis* oocytes defolliculated with collagenase[10,21]. Controls received 12.5 ng globin mRNA only. The oocytes were preincubated for 2 h before labelling. Incubations were performed in Barth medium[30] in the presence of penicillin (10 μg ml^{-1}) and protease inhibitors[31]. The translation products were separated on a 10–20% (w/v) linear acrylamide gradient SDS-gel[32] and visualized by fluorography[33].

reduced in the reticulocyte lysate system with mRNA prepared in the absence of ^{7}mGpppA (data not shown).

β-Lactamase mRNA synthesized and capped *in vitro* was microinjected into oocytes and the translation products were labelled with ^{35}S-methionine. Globin mRNA was co-injected as an internal control. Globin was clearly seen among the products inside the oocyte, whereas the endogenous background did not allow a definite identification of a β-lactamase band (Fig. 1, lanes 12, 13). In the medium of oocytes incubated for 12 h with ^{35}S-methionine, a major band was seen at the position of β-lactamase (compare Fig. 1, lanes 7 and 8) which was absent from the medium of control oocytes (lane 9). The levels of β-lactamase in the medium increased after the chase period (lanes 10, 11), while globin was undetectable (lanes 8–11), excluding the possibility of nonspecific leakage from the oocytes.

Independent proof for the secretion of β-lactamase from *Xenopus* oocytes was obtained by measurement of the enzymatic activity in the medium. Nitrocefin was used as a sensitive chromogenic substrate of β-lactamase[19] (Fig. 2). The medium of oocytes injected with plasmid-coded mRNA contained significant activity whereas globin mRNA-injected controls were negative. Again, in accordance with the labelling experiments, more β-lactamase was found after the chase period than before it.

Rough estimates of the number of enzyme molecules secreted by the oocytes could be obtained from both types of experiments. Using the radioactivity in the β-lactamase band and the methionine content of oocytes[20], it was calculated that 3×10^{10} molecules per oocyte were synthesized and secreted. Using enzymatic activity it was estimated that 10^{10} molecules of β-lactamase were secreted by one oocyte in 24 h (the specific activity of pure β-lactamase was assumed to be 200 units per mg[17]). These values compare favourably with estimates of the amount of eukaryotic secretory proteins synthesized in and exported from oocytes[10,21]. Also, the time periods between synthesis of the polypeptides and their appearance in the medium

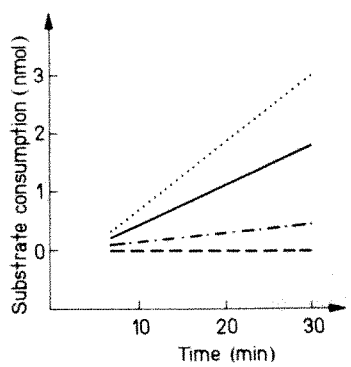

Fig. 2 Detection of β-lactamase activity in the medium of oocytes injected with plasmid-coded mRNA. The β-lactamase activity was measured with nitrocefin as a chromogenic substrate (0.2 mg ml^{-1} in 50 mM phosphate buffer, *p*H 7.0) by the increase of the absorbance at 482 nm. The medium of two oocytes injected with pBR322-coded RNA and globin mRNA was tested after 12 h pulse-incubation (—·—) or after an additional 22 h of chase (——). A test with chase medium obtained from four oocytes (·····) showed nearly double the rate. Control oocytes received globin mRNA (— — —).

are similar (see ref. 22). Thus, the bacterial secretory protein may be handled in the eukaryotic cell with similar efficiency to a genuine eukaryotic protein.

Our results indicate that a signal peptide is sufficient to trigger secretion, even in a complex eukaryotic cell, and that no further topogenic information and corresponding recognition systems are needed after traversal of the membrane. Conversely, one may assume that non-secretory, soluble proteins, located in the lumen of the reticular system of a eukaryotic cell, need some device to prevent their secretion. For lysosomal enzymes of fibroblasts, for example, this mechanism appears to be the mannose 6-phosphate receptor pathway (for review see ref. 23).

Our results do not imply that every protein without a sorting signal will be secreted once it has passed the rough endoplasmic reticulum membrane. Poor solubility or special affinity to membranes can interfere with intraluminal transport (for examples see refs 24, 25).

We thank Dr B. Dobberstein for the supply of ^{7}mGpppA, Dr S. Prösch for help with plasmid DNA preparation and restriction enzyme cleavages, Dr Fleck (ZIMET, Jena) for a gift of nitrocefin, and Drs U. Kießling, P. Langen, S. M. Rapoport, M. Strauss and H. Welfle for critical reading of the manuscript.

Sexual preference of apparent gene conversion events in MHC genes of mice

Dennis Y. Loh & David Baltimore

Whitehead Institute for Biomedical Research; Center for Cancer Research and Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

Polymorphisms exist at many genetic loci. At some loci, however, polymorphism is so high that tens and even hundreds of different alleles coexist in the population. Two such highly polymorphic systems are the immunoglobulin genes and the vertebrate major histocompatibility loci. The origin and maintenance of highly polymorphic loci remain open to debate but it seems likely that special mechanisms contribute to their variability and that their polymorphism serves important biological roles. The high degree of polymorphism at the *H-2* class I major histocompatibility locus of the mouse has been documented by both tissue transplantation and serological methods[1]. More recently, molecular cloning and DNA sequencing of some of the class I genes has shown that most of the sequence variability is concentrated in the first two domains and is often found in clustered regions within them[2–4]. In addition, several groups have suggested that gene conversion events among the many class I genes may contribute to *H-2* polymorphism[5,6]; such events would have to occur during meiosis to produce heritable alterations. The strongest evidence for gene conversion comes from sequence analysis of mutant class I *H-2* alleles where concerted changes at adjoining sites in DNA imply gene conversion by distant but closely related loci[5,6]. We report here an analysis of these mutants indicating that the chromosomes containing loci that have experienced gene conversion originated from females. These data suggest a striking preference for mammalian meiotic gene conversion events during female rather than male gametogenesis.

The existing *H-2* mutants were originally identified by circular skin-grafting experiments among sibling mice[7,8]. This system of mutants is notable because: (1) the rate of observed mutation is very high, about 1 in 2,500; (2) individual mutational events result in multiple amino acid substitutions; (3) independent mutants have identical, multiple changes; and (4) in most cases, the newly introduced amino acid sequences are found in the same configuration in one of the other genes of the major histocompatibility complex (MHC). Two independent groups have recently shown unequivocally that in the case of the *bm1* mutant, a gene conversion-like event resulted in the substitution of a piece of DNA in the middle of the gene, producing the K^{bm1} gene[5,6].

While considering possible mechanisms for this high rate of gene conversion we were struck, as others had been previously[9], by the apparent allele specificity of the conversion process. In the initial experiments, where skin grafts among (C57BL/6 × BALB/c)F_1 mice were performed, mutation was observed at the K^b locus to the almost total exclusion of alternative available loci (K^d, D^b, D^d and L^d). The results suggested that perhaps K^b is especially prone to alteration or possibly that changes in K^b were more easily recognized than others using a skin graft assay. The K^b gene, however, has no obvious uniqueness in its sequence and, since the initial experiments, mutations at other loci have been found. While puzzling over the existing data, a previously unrecognized feature became apparent. In the initial experiments, the F_1 mice all originated from mating C57BL/6 females with BALB/c males[7,9–11]. Thus, the K^b allele was always contributed through the egg rather than the sperm. A review of all available data in which the origin of a mutated allele could be traced because the investigators used F_1 mice, showed that in every case, the mutation arose in a chromosome contributed by the egg (Table 1)[7,8]. For this compilation, only mutants of the spontaneous gain/loss type were included because these are the ones most likely to involve a gene conversion-like event. (A gain/loss type mutant is one in which both the mutant and the parental type reciprocally reject skin grafts consistent with the simultaneous loss of one transplantation antigen and the acquisition of another.) There were 16 cases found, 9 of which involved K^b, 3 of which involved other *b* haplotype alleles and 4 of which were in maternal chromosomes from other haplotypes (Table 1). In one case, mutation in K^d was found in a strain where the *d* haplotype was maternal and the *b* haplotype paternal.

Gene conversion apparently occurred exclusively on maternal chromosomes in all cases examined. A maternal K^b allele was involved in many of these cases and if it had special properties then it would skew the data for reasons unrelated to the sex of the chromosome donor. Without the K^b events, however, all of seven cases were maternal, which would occur by chance with

Table 1 Gain/loss *H-2* mutants

Mutants	Affected locus	Maternal *H-2* haplotype	Paternal *H-2* haplotype	F_1 cross in which mutation arose
bm1	K^b	*b*	*d*	C57BL/6By × BALB/cBy
bm2	K^b	*b*	*d*	C57BL/6By × BALB/cBy
bm4	K^b	*b*	*d*	C57BL/6By × BALB/cBy
bm7	K^b	*b*	*d*	C57BL/6By × BALB/cBy
bm9	K^b	*b*	*d*	C57BL/6By × BALB/cBy
bm10	K^b	*b*	*d*	C57BL/6By × BALB/cBy
bm11	K^b	*b*	*d*	C57BL/6By × BALB/cBy
bm12	A^b_β	*b*	*d*	C57BL/6By × BALB/cBy
bm13	D^b	*b*	*d*	C57BL/6By × BALB/cBy
bm14	D^b	*b*	*d*	C57BL/6By × BALB/cBy
fm1	K^f	*f*	*a*	A.CA/SnK1/Eg × A./Sn
fm2	D^f	*f*	*r*	B10.M × B10.RIII(71NS)
KH162A	K^d–IA^d	*d*	*b*	BALB/cKh × C57BL/6Kh
KH170	K^b	*b*	*d*	C57BL/6Kh × BALB/cKh
KH171	K^b	*b*	*d*	C57BL/6Kh × BALB/cKH
dm5	K^d	*d*	*b*	BALB/cKh × C57BL/6Kh

The origins of the mutants, together with the affected loci, are shown. For completeness, the table includes mutant *bm12*, which has a mutation in the A_β gene, and KH162 which has not been further characterized other than to be in the K^d–IA^d region. For details of the various origins of these mice see refs 7, 11.

a <1% probability. Although the rates of occurrence of gain/loss type mutants vary considerably, the events at K^b do not seem to be more frequent compared with other events in other haplotypes[12]; rather, K^b events are more frequent than D^b events. We conclude, therefore, that gene conversion events (if all MHC mutants have such an origin) are much more frequent in oogenesis than in spermatogenesis and possibly never occur during male gametogenesis. Although there are no available data for analysing any other gene system, it is reasonable to expect that in other multi-gene families, like immunoglobulin variable-region genes, the same specificity of gene conversion events might pertain.

Although gene conversion events in lower eukaryotic organisms are often associated with recombination of flanking markers[13], the localized gene conversion events at MHC and immunoglobulin genes are not known to have such an association. It may be relevant, however, that the intra-*H-2* recombination rate is 0.32% in females and 0.19% in males[12]. The excess rates in females are possibly associated with gene conversion events.

Although our analysis indicates preferential if not exclusive gene conversion in maternal gametogenesis, the preference of *H-2K* conversion over *H-2D* conversion still requires explanation[7]. Perhaps there is a polarization of events along the chromosome or some specificity associated with K^b structure.

Nonspecific integration of the HTLV provirus genome into adult T-cell leukaemia cells

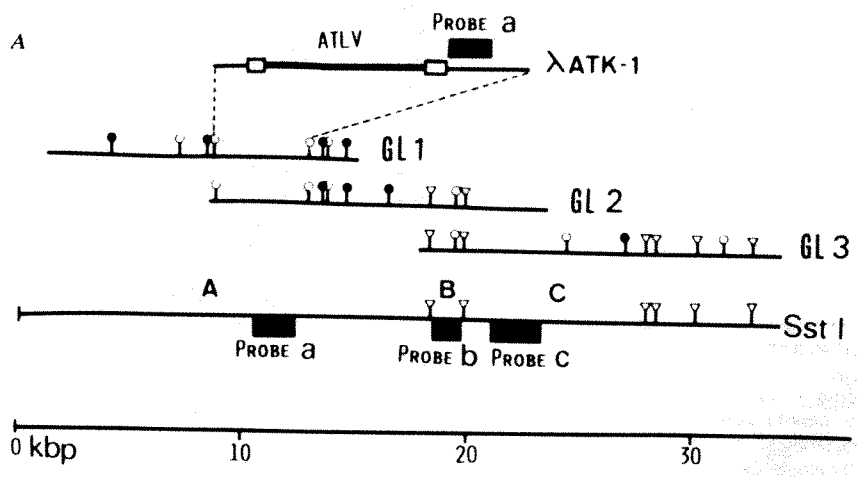
Motoharu Seiki, Roger Eddy*, Thomas B. Shows* & Mitsuaki Yoshida

Department of Viral Oncology, Cancer Institute, Kami-Ikebukuro, Toshima-ku, Tokyo 170, Japan
* Department of Human Genetics, Roswell Park Memorial Institute, New York State Department of Health, Buffalo, New York, USA

Human T-cell leukaemia virus (HTLV)[1–4], previously also reported as ATLV[5], is a recently identified retrovirus which is closely associated with adult T-cell leukaemia (ATL) endemic in south-western Japan[6,7] and the Caribbean[8]. Determination of the total nucleotide sequence of the HTLV genome has revealed no typical *onc* gene acquired from the cellular sequence[9,10]. Screening of the HTLV provirus genome in tumour cells[4,11,12] has shown that in all cases of ATL examined, the primary tumour cells contained the provirus genome and were monoclonal with respect to the integration site of the provirus[13]. These findings suggest that ATL leukaemogenesis may be due to insertional mutagenesis in which the provirus genome is integrated into a specific locus on the chromosomal DNA and then activates an adjacent cellular *onc* gene, a mechanism already demonstrated in avian lymphoma[14,15] and erythroblastosis[16] induced by avian leukosis viruses. A common site of HTLV provirus integration in leukaemic cells among some ATL patients was reported by Hahn *et al.*[17] but subsequently retracted[18]. However, this retraction does not imply the random integration of the proviruses. Independently, we have been testing this insertional mutagenesis model in ATL and report here that the provirus did not have a common locus of integration in 35 ATL patients and did not integrate on the same chromosome in 2 ATL patients.

As previously reported, the leukaemic cells of most ATL patients contain one or two copies of HTLV provirus[4,11], but the size of the *Eco*RI-digested DNA fragment containing the provirus and cellular flanking sequences differs between individuals, suggesting that the integration sites of the HTLV provirus in these patients are not identical. However, even if the actual chromosomal integration sites are different, it is still possible that proviruses integrated into one or a few common regions could explain the activation of a unique cellular gene. The strategy used was to examine the rearrangements of cellular DNA sequences by provirus integration. By using specified probes, we could detect the integration of provirus into any site within specified DNA fragments. We chose the DNA clone λATK-1 (ref. 10), which had been isolated from fresh leukaemic cells of an ATL patient (KKT). As these cells had only one copy of the provirus genome[10], the provirus must be involved in initiating or promoting leukaemic cell growth. The cellular flanking sequence of this provirus could therefore be used as a chromosomal site-specific probe to test the significance of provirus integration into the tumour cell DNA.

The unique cellular sequence flanking the 3′ long terminal repeat (LTR) was subcloned into pBR322 and used as probe *a* (Fig. 1*a*) for screening a human gene library to isolate clones covering wider regions around the provirus integration site. Isolation of three independent clones (GL1, GL2 and GL3) and construction of their restriction maps resulted in three *Sst*I fragments (A, B and C, Fig. 1*A*) covering a region of about 28 kilobases (kb) around the provirus integration site in leukaemic cell DNA of patient KKT. We subcloned the unique sequences *a*, *b* and *c* from fragments A, B and C, respectively, and used them as probes to detect DNA rearrangements in *Sst*I digests of leukaemic cell DNA from 35 other ATL patients. As *Sst*I does not cut the viral sequences, the integrated fragments with the HTLV provirus sequence should have higher molecular weights than the original fragments A, B and C. Figure 1*B* shows some results of screening using probe *a*. In addition to the normal cellular fragments, a rearranged larger fragment was detected in the control DNA of patient KKT from which the original clone was isolated, but no such rearranged fragments were detected in the DNA of the other ATL patients. These results were confirmed by rehybridization of the same filters using viral probes that detected co-migration of the only provirus sequence with the rearranged fragment of patient KKT (Fig. 1*c*). No DNA rearrangements were detected with probes *b* and *c* (data not shown). This absence of a common region for provirus integration in leukaemic cells suggests that it is unlikely that ATL is caused by simple insertional mutagenesis.



This conclusion is based on analysis of a single locus of a provirus integration in only one case of ATL, which could be an exceptional case. To exclude this possibility, we isolated another clone, λATY, from fresh leukaemic cells of another ATL patient (MYK). Blotting analysis showed that these leukaemic cells also contained only one copy of the provirus genome. The unique cellular flanking sequence in patient MYK was subcloned and used as a probe in the same way as described above. This probe (probe *d*) detected an 8-kb fragment in the *Hin*dIII digest of normal cellular DNA and a 10.5-kb rearranged fragment in the digest of DNA from patient MYK (data not shown). Again, probe *d* did not detect any rearranged fragment

Probe *a* (KKT), A in Fig. 3; probe *d* (MYK), B in Fig. 3. % Discordancy indicates the frequency that probes do not co-segregate with a specific human chromosome. Human chromosomes were determined by analysing each cell hybrid for enzyme markers encoded on each human chromosome as described previously[21]. $+^{w}$, weak band.

* Chromosome Y is not involved as human female parental cells were used.

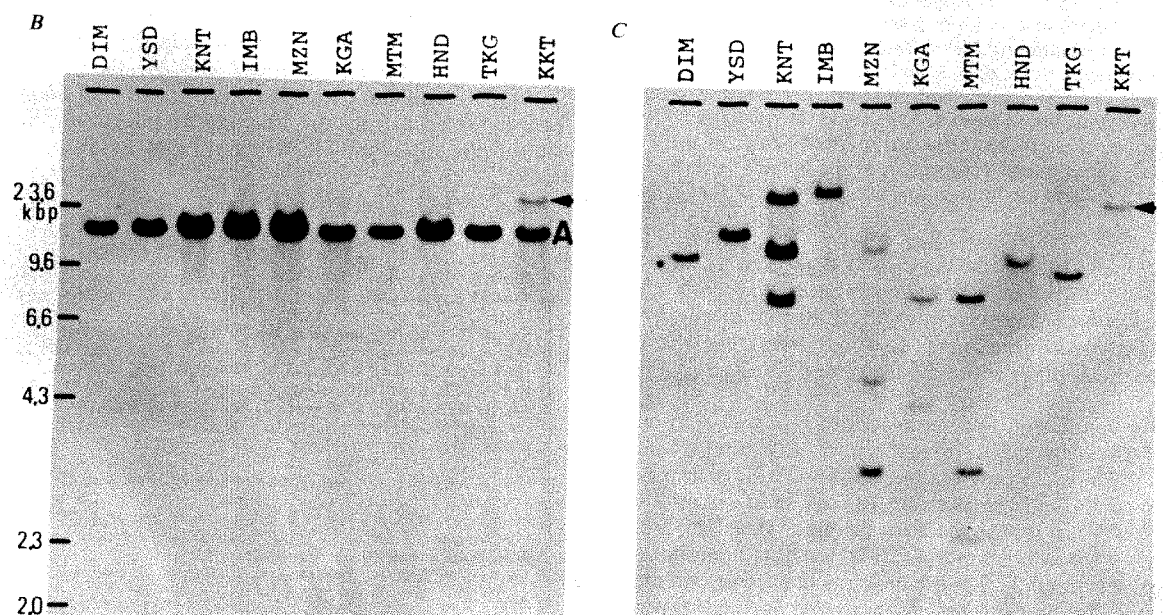

Fig. 1 Analysis of provirus integration sites in leukaemic cells from ATL patients using probes of cellular flanking sequences. *A*, Clones GL1, GL2 and GL3 of cellular DNA adjacent to the provirus genome integrated into leukaemia cells of a patient (KKT) were isolated from a human gene library using probe *a* and then probe *c*, and the restriction map was constructed. Probes *a*, *b* and *c* were separately subcloned into pBR322. ♀, *Eco*RI; ♦, *Hin*dIII; ♈, *Sst*I. *B*, DNA samples from fresh leukaemic cells of independent ATL patients were digested with *Sst*I, fractionated in 0.8% agarose gel and transferred to a nitrocellulose filter. The filter was hybridized with ^{32}P-labelled probe *a*. Lane KKT is DNA from which the original provirus clone λATK-1 was isolated, and other lanes are DNAs from other ATL patients. A indicates normal fragments detected by probe *a*. The fragment rearranged by provirus integration is indicated by an arrow. *C*, The filter used in *B* was washed in boiling water for 10 min and used for a second hybridization with ^{32}P-labelled HTLV representative probe.

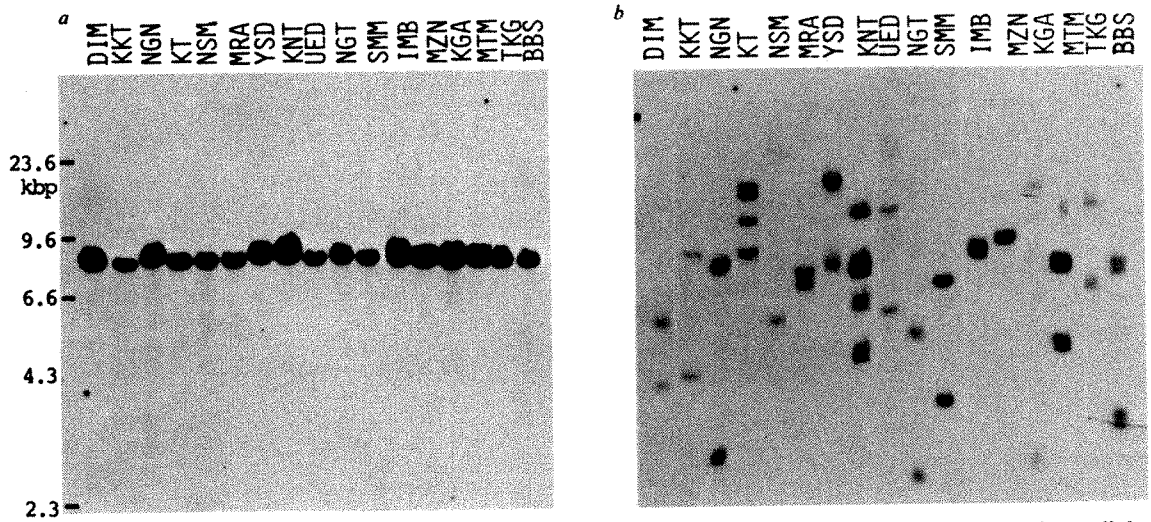

Fig. 2 Analysis of provirus integration sites in DNA of leukaemic cells from ATL patients with a second independent cellular flanking sequence. *a*, The filter was hybridized with ^{32}P-labelled probe *d*. *b*, The same filter was hybridized with ^{32}P-labelled HTLV as representative probe. Molecular clone λATY was obtained from an *Sst*I digest of DNA from another ATL patient (MYK) according to the methods reported previously[9]. The unique cellular sequence adjacent to 3′ of the provirus was subcloned from the *Hpa*II digest of λATY into pBR322 and used as probe *d*. DNA samples from ATL patients were digested with *Hin*dIII and analysed as in Fig. 1.

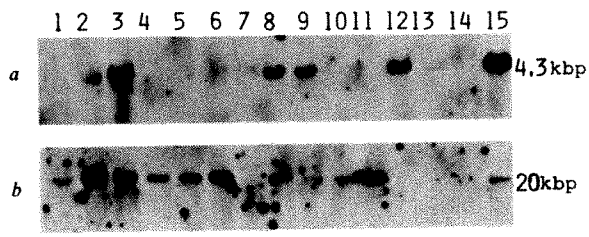

Fig. 3 Distribution of cellular sequences flanking adjacent integrated proviruses among human–mouse somatic hybrid cells containing different sets of human chromosomes (see Table 1). Hybridization of ^{32}P-labelled probes *a* (panel *a*) and *d* (panel *b*) to *Eco*RI-digested DNA from somatic cell hybrids (lanes 1–13), mouse (lane 14) and human (lane 15) cultured cells[22–24] after DNA fragments had been separated by electrophoresis and transferred to nitrocellulose filter. Probe *a* hybridizes to a 4.3-kb fragment and probe *d* hybridizes to a 20-kb fragment but neither hybridizes to mouse in these conditions. Cell hybrid DNAs either contain the human sequence (+) or do not (−), depending on the human chromosome composition of the hybrid cells. In panel *a*, probe *a*-positive hybrids are in lanes 2, 3, 7 (weak), 8, 9, 12 and 13. In panel *b*, probe *d*-positive hybrids are in lanes 1–6, 8, 10 and 11. The human chromosome constitution of the hybrids is listed in Table 1; the hybrids are listed in the same order as in the figure.

in 17 ATL cases (Fig. 2). In the *Eco*RI digests of 12 cases of ATL, probe *d* detected a 20-kb fragment covering a much wider region than the 8-kb fragment in *Hin*dIII digests, but again no rearranged fragments were found (data not shown). These results also support the findings with probes *a*, *b* and *c* described above (Fig. 1).

The above conclusion is consistent with reported restriction patterns of provirus DNA in leukaemic cells from 78 ATL patients[11,13]. Thus, the provirus integration of HTLV into ATL cells seems to differ from that in tumours induced by avian leukosis virus[14–16] or mouse mammary tumour virus[19,20], which possess one or several common loci for provirus integration.

However, it is possible that the provirus integrates into many chromosomal sites on the same chromosome. To test this possibility, we analysed the specificity of provirus integration at the chromosomal level by using the somatic cell hybrid strategy for mapping human genes on specific chromosomes[21]. Human × mouse somatic cell hybrids characterized for their human chromosomal content were analysed for probes *a* and *d*. DNA was extracted from these hybrid cells and separately analysed by the two probes on the same filter (Fig. 3). The chromosomes in which the proviruses are integrated segregated independently in cell hybrids (Table 1), demonstrating that integration occurs on different chromosomes. Analysis of the distribution of the probes in the cell hybrids tested in Fig. 3 demonstrates that probe *a* co-segregated with chromosome 7 and probe *d* co-segregated with chromosome 17 (Table 1). With the small number of cell hybrids tested, the evidence strongly suggests that the sequences recognized by probes *a* and *d* are located on chromosomes 7 and 17, respectively. Results from 15 additional hybrids tested similarly, support the chromosome mapping evidence in Table 1 (data not shown).

The absence of chromosomal specificity of the provirus integration between two ATL patients is consistent with the absence of a common integration site shown by blotting analysis of the provirus sequence in leukaemic cells. These data strongly suggest that provirus integration in tumour cells occurs at random sites.

We thank Dr H. Sugano for encouragement throughout this work, also Dr S. Hattori for valuable discussion and Ms Y. Hirayama, L. Haley, M. Byers and M. Henry for technical assistance. This work was partly supported by a grant-in-aid for cancer research from the Ministry of Education, Science and Culture in Japan and USPHS grant GM 20454.

ACADEMIC PRESS announces a NEW JOURNAL...

Journal of Symbolic Computation

Editor: B. Buchberger *(Austria)*

Associate Editors: W. Bibel *(Federal Republic of Germany)*, **J. Cannon** *(USA)*, **B. F. Caviness** *(USA)*, **K. Fuchi** *(Japan)*, **G. Huet** *(France)*, **R. Loos** *(Federal Republic of Germany)*, **Z. Manna** *(USA)*, **J. Nievergelt** *(Switzerland)*, **D. Yun** *(USA)*, **J. H. Davenport** *(UK)*.
... in cooperation with a distinguished international editorial board.

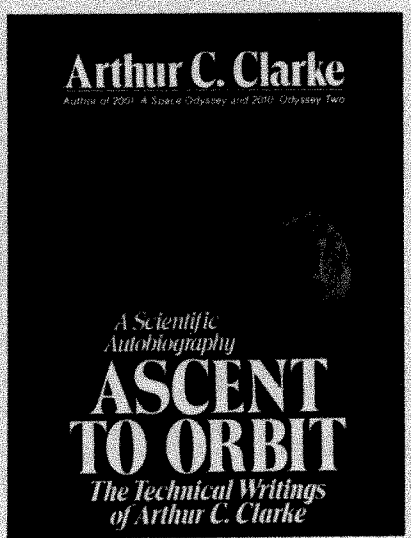
The **Journal of Symbolic Computation** will publish original articles on all aspects of the algorithmic treatment of symbolic objects (terms, formulae, programs, algebraic and geometrical objects). The emphasis will be on the mathematical foundation, correctness and complexity of new sequential and parallel algorithms for symbolic computation. However, the description of working software systems for symbolic computation and of general new design principles for symbolic software systems and applications of such systems for advanced problem solving are also within the scope of this journal.

Typical topics to be treated in the journal are:

Symbolic integration, symbolic summation, symbolic solution of differential equations and of other problems in analysis • term simplification • arithmetic in basic and higher algebraic domains • symbolic solution of equations and systems of equations • computational group theory • computational number theory • computational problems in non-associative and other algebras • algorithmic combinatorics • algorithmic geometry • computational aspects of algebraic geometry • algorithms in coding theory and cryptography • interface between symbolic and numerical algorithms • universal automated theorem proving • unification • automated theorem proving in special theories • automated proof checking • automatic program synthesis • automatic program transformation • automatic program verification • symbolic execution of programs • algorithmic treatment of abstract data type specifications • interpreters for high-level programs (functional programs, rewrite rule programs, logic programs) • design issues of software systems for symbolic computation • descriptions of working software systems • descriptions of typical systems applications • symbolic computation and math teaching

In addition to original papers, the journal will regularly publish invited tutorial surveys on subareas of symbolic computation and on recent research trends.

Submission of manuscripts:



Please submit in triplicate to: *B. Buchberger, Journal of Symbolic Computation, Johannes-Kepler-Universitat, A4040 Linz, Austria.*

NEW FROM ARTHUR C. CLARKE . . .

ASCENT TO ORBIT
The Technical Writings of Arthur C. Clarke

Well before Arthur C. Clarke introduced HAL to the world in *2001: A Space Odyssey*, he was already well known to a select group of readers as the first scientist to suggest the idea of satellite communications and its implications for 20th Century space technology. *Ascent To Orbit* brings together for the first time Clarke's major scientific writings — works of insight and imagination which presaged many of the modern breakthroughs in space science.

Culled from his more than 40 years of research and writing *Ascent To Orbit* traces chronologically Clarke's fascinating thoughts on the beginnings of satellite communication, rockets and warfare, electronics and space flight, the "space elevator," and strategies for interstellar robot probes.

Each of the 25 articles is introduced by an original, autobiographical essay prepared by the author for this volume. Peppered with personal insights and humorous anecdotes, these revealing essays draw clear connections between Clarke's informal and formal scientific thinking and, in many instances, foreshadow his later contributions to the world of science fiction writing.

With the recent explosion of popular interest in science *Ascent To Orbit* promises a unique account of Clarke's role in shaping and interpreting space exploration, telecommunications, and related high technology.

ASTRONOMY
Fundamentals and Frontiers, 4th Edition

by **R. Jastrow,** *Dartmouth College,* and **M.H. Thompson,** *Dalton Schools, New York, NY.*

This is a thorough revision of the established text for a first course in astronomy, providing a highly readable, authoritative and pedagogically proven blend of contemporary information and imaginative illustrations on astronomy. New to this edition is up-to-date coverage of galaxies and interstellar matter, and an essay on the history of astronomy.

March 1984 — 576 pages
0471 89700 0 — £25.40

GALACTIC X-RAY SOURCES

edited by **P.W. Sanford,** *Department of Physics and Astronomy, University College, London, Mullard Space Science Laboratory;* **P. Laskarides,** *Department of Astronomy, University of Athens,* and **J. Salton,** *Department of Physics and Astronomy, University College, London, Mullard Space Science Laboratory*

This book is a comprehensive introduction to galactic x-ray sources and assumes little previous knowledge of the subject, which is now seen as an integral part of modern astronomy. It is based upon the material presented at an Advanced Study Institute sponsored by NATO, which was held at Cape Sounion in Greece and was an attempt to exchange ideas and form bridges between specialists and young astronomers.

April 1982 — 468 pages
0471 27963 3 — £21.00

BLACK HOLES, WHITE DWARFS, AND NEUTRON STARS
The Physics of Compact Objects

by **S.L. Shapiro** and **S.A. Teukolsky,** *both of Cornell University*

A self-contained investigation of the physics of compact objects (neutron stars, black holes, white dwarfs), presenting the latest observations and theoretical developments. It introduces the necessary concepts and mathematical tools and analyzes the physical properties of the star in the "ground" state, and when subjected to "perturbations" it provides one-dimensional analytic model calculations. Includes over 250 problems and answers to exercises plus computer problems.

July 1983 — 666 pages
0471 87317 9 — (cloth) £44.30
0471 87316 0 — (paper) £20.45

THE PHYSICS OF STARS

by **S.A. Kaplan,** *formerly of the Department of Physical and Mathematical Sciences, Gorky University, USSR*
Translated by **R. Feldman,** *Nice Observatory, France*

Father, mother and son

Peter Kemp

H.G. Wells: Aspects of a Life. By Anthony West.
Random House/Hutchinson: 1984. Pp.405. $22.95, £12.95.

H.G. Wells: Aspects of a Life opens bizarrely not with the birth of its subject but the birth of the biographer — Anthony West, Wells's illegitimate son. At first startling, this emerges as rather appropriate, since, for most of the book, West's technique is to superimpose his own situation upon his subject-matter. Ultimately, it comes to seem, the aspects of a life being illuminated here are not so much Wells's but West's.

Even structurally, the book throws West into unexpected prominence — not only starting with his birth but ending at the moment when he resolved to write his father's life. The way he has gone about this is idiosyncratic, too. Most attention is devoted to the numerous women with whom Wells was involved, West's mother — the writer Rebecca West — attracting a particularly long and loathing commentary. Savage disparagement is further lavished on literary figures whose paths crossed Wells's, especially Henry James, George Bernard Shaw and George Gissing.

West's unusual handling of his material means that the real shape and substance of Wells's life get obscured — especially the trajectory he followed from a dismally disadvantaged background to fame as a novelist then descent into the role of wordy opiner on world affairs. Fuelling that progress was fierce energy. Born to parents just subsisting in a floundering little shop, Wells seemed destined — like his brothers — to life as a draper's assistant. What saved him was science. Angrily and admirably elbowing his way to an education, he eventually won a scholarship to the Normal School of Science. Here, he was taught by T.H. Huxley — who influenced him in two crucial ways. He instilled into him the importance of taking a biological view of life: something that gives Wells's writings — despite their surface diversity: fiction, Utopias, encyclopaedias, biography, autobiography, polemic and propaganda — an essential unity. And his career showed Wells what might be achieved by pugnacious advocacy of scientific training.

Initially, Wells's educational impulse took him into school-teaching. Ill health ended this. But, when he began writing, the impulse stayed with him: didactic hypotheses are fruitfully yoked to imaginative excitements in the early scientific romances — *The Time Machine, The Island of Doctor Moreau, The Invisible Man, The War of the Worlds, The First Men in the Moon* and so on — that established him as an intriguingly new kind of creative figure.

From *H.G. Wells: Aspects of a Life*

Huxley's student — H.G. Wells at the Normal School in South Kensington.

Strangely, when it comes to conveying the nature of Wells's achievement, West concentrates on his inferior, post-1914 writing. Preferring the journalist to the novelist, he lauds the bombastic and ephemeral newspaper work turned out — indeed, churned out — when Wells was straining to establish himself as a kind of global guru. Given more perfunctory treatment is the period of real brilliance in Wells's career — his first two decades as an author: when he turned the dreary and debilitating events of his early life into bracingly resilient comic fiction, and channelled the intellectual energies generated by his studies with T.H. Huxley into powerful, pulsing science fiction. Confusing notoriety with notability, West appears most impressed by the later Wells — "a world figure whose name was known wherever books were printed and newspapers were sold", "a very big man indeed".

Besides beating the drum for this strutting public figure, West is concerned with putting an attractive gloss on Wells's private affairs. It is here that his book becomes most extraordinarily personal. The idea of writing his father's life came to him, West reveals, when he was brooding over the fact that someone seemed to have lied to Wells about him, alleging that he belonged to a pro-Nazi conspiracy. Appalled at "The wilful interpolation of a piece of fiction into the facts of my life", West was struck with horror at the thought that just such another "nightmare cobweb of lies" might be draped across Wells's biography. Accordingly, he resolved "to devote the necessary time and effort required to keeping the record of what my father had been, and of what he stood for, more or less straight".

Crooked records are an *idée fixe* in this book. West finds doctored documents everywhere. His grandmother apparently concocted an "appalling fabricated diary". His mother, he claims, bequeathed to posterity a trumped-up tissue of falsifications about her relationship with Wells — drafts or summaries of letters that never existed, invented incidents, fake quotations. Another woman novelist who became Wells's mistress, Dorothy Richardson, is likewise sourly indicted of compulsive mendacity about their affair. Even a male friend of Wells's, the novelist George Gissing, gets denounced as a "veiled and secretive fraud", an obsessive "fabulist" for whom "the transformation of the truth was the name of the game".

All of this needs viewing sceptically. It is, it transpires, a habit of West's to assail people for doing what he does himself: at one point, with the shattering imprudence of the stone-thrower in the glass-house, he even lobs abuse at someone for "producing studies of the lives of dead writers". Regularly, he protests about the snobbery often shown towards Wells — while at the same time indulging himself in a very socially sniffy tone, turning up his nose at "provincials who lived in a provincial backwater", "second-raters" in "the obscurer colleges of the older universities", and Dorothy Richardson's "not very dazzling receptionist's job". Constantly, people are rapped over the knuckles for taking hearsay on trust. Yet this is West's habitual procedure: most of his story of Gissing's relations with his se-

cond wife, Edith, for instance, consists of West's account of Wells's account of a doctor's account of Gissing's account of his dealings with Edith — the resulting hodge-podge being, unsurprisingly, grotesquely at variance with Gissing's direct record of events in his diary. Quotations from Gissing's letters are scrambled too — up to five distortions in six lines — giving a misleadingly unpleasant slant to things: he's made to refer to his son as "it" not "he", his wife as "the woman" not "the poor woman".

What seems to be happening here is that facts about Gissing's life are being slid around until they fall into a pattern fitting West's preoccupations. Ferociously, West clamps the complex of feelings stemming from his lonely and divided childhood around other people. In his *Experiment in Autobiography*, for instance, Wells recounts how as a boy, when tossed playfully into the air by a youth teasing him with "Whose little kid are you?", he fell and broke his leg. This was, he observes, actually a lucky break: confined to bed and plied with delicacies and books by the youth's mother, he acquired that appetite for reading and knowledge that, via his exhilarating educational experiences studying biology with Huxley, eventually launched his career: "Probably I am alive to-day and writing this autobiography instead of being a worn-out, dismissed and already dead shop-assistant, because my leg was broken". West's interpretation of events is strikingly different: the youth, he believes, "had really put him on the spot with his question: Whose little kid was he, his father's or his mother's?"; he "had been asking him to take sides" and "The probability is that he had been trying to blurt out his father's name when he was dropped", so "It must have seemed as if he had been punished for wanting to be his father's boy".

There is, in fact, nothing in Wells's account to warrant the assertion that he was being asked which parent he preferred, or that he "had been terribly torn between being his mother's boy or his father's". West, however, has spent his life caught in the tensions of such a pull — as his novel *Heritage* about his filial fight against Rebecca West makes only too clear. His new book seems one more round in the psychic tug-of-war between what he calls in a sadly revealing phrase "the father of my dreams", and the mother whose accounts of other people "however sharply detailed and however plausible in their *trompe l'oeil* literalness, are expressive of her states of feeling rather than descriptions of actual . . . occurrences". Ironically, on the evidence presented here, West establishes himself not so much as his father's champion as his mother's son. □

Peter Kemp is Senior Lecturer in English at the Middlesex Polytechnic, London, and author of H.G. Wells and the Culminating Ape *(Macmillan, London, 1982).*

Processes of natural waters

J.D. Burton

Principles of Aquatic Chemistry.
By François M.M. Morel.
Wiley: 1983. Pp.446.
£42.55, $49.95.

THE study of chemical processes in natural waters tends to be pursued in compartments — oceans, lakes, rivers, groundwaters and so on. One reason for this lies in the large differences between such environments regarding the spatial and temporal frameworks within which geochemical processes can operate. Another is the contrast in ionic strength between saline and fresh waters, which to some extent imposes different strategies upon the application of both analytical techniques and physicochemical concepts.

Nevertheless, underlying the diversity of geochemical phenomena in natural aquatic systems is a limited number of physicochemical processes which also underlie the chemical behaviour of constituents in treated waters and aqueous wastes.

Professor Morel's textbook is the latest of several which have presented the chemistry of natural aquatic environments in the context of basic physicochemical principles. The first three chapters give a concise and clearly developed introduction to solution chemistry. The subsequent treatment of natural water chemistry is organized along lines dictated by the main types of reactions which have to be considered: acid–base chemistry, solubility equilibria, complexation, redox chemistry and surface chemistry. The tone is firmly didactic and numerical examples are widely used. Any such approach must be rooted in equilibrium systems but the importance of kinetic factors in determining what happens in the environment receives appropriate emphasis. The dominance of inorganic topics largely reflects the relatively backward status of attempts to apply physicochemical concepts to the behaviour of organic compounds in natural waters.

The author says that sometimes he has used "a cumbersomely detailed algebraic and numerical development" but this will be considered an advantage by many students trying to make the transition from description to a more rigorous approach. They will be assisted also by the frequency with which the text turns to the processes as they operate in nature, topical matters such as photochemistry and hydrothermal processes at ridge-spreading centres being included.

The material covered is inevitably similar to that dealt with in the well-established text by Stumm and Morgan, also published by Wiley, which went into a new edition in 1981. The present book has its own virtues, however, and should join *Aquatic Chemistry* on the desks of workers in the field. It is to be hoped that a cheaper edition may soon make it more accessible to students. □

J.D. Burton is Reader in Chemical Oceanography at the University of Southampton.

Yeasts and industry

Julius Marmur

Yeast Genetics: Fundamental and Applied Aspects.
Edited by J.F.T. Spencer, Dorothy M. Spencer and A.R.W. Smith.
Springer-Verlag: 1984. Pp.533. DM148, $57.50.

IN 1970, Dr G.R. Fink offered the advice that "biochemists as well as geneticists should use only S288C or 'isogenic' *Saccharomyces* strains in their investigations. Regrettably, this has not been the rule in the past". True, the principal yeast of industrial importance is *S. cerevisiae*. However, there are over 400 yeast strains, harbouring a vast resource of genes encoding enzymes that carry out a variety of chemical transformations. What is very much needed is the comparative genetic and biochemical characterization of some of the more versatile strains, making use of classical and modern genetics.

J.F.T. Spencer and his colleagues have assembled a book on the principle that "the methods of yeast genetics have many things to offer the breeder of industrial yeast strains". Thus, there are chapters on topics ranging from gene conversion to the breeding of brewing strains. While some subjects, such as gene conversion (dealt with here by Fogel, Mortimer and Lusnak) are handled in exquisite detail, others, nucleic acid relatedness among yeasts (Kurtzman, Phaff and Meyer), for example, are covered in a broad-based manner, bringing together a great deal of information that is otherwise hard to come by.

In addition to those subjects already mentioned which are "concerned with the nuclear yeast genome", there are chapters on the yeast cell division cycle (Carter, Piggott and Walton), meiosis and sporulation (Dawes), and radiation sensitivity and repair (Game). Particularly good is Elizabeth Jones's wide-ranging contribution on the genetics and biochemistry of yeast proteases and their inhibitors.

Extrachromosomal genetic elements are covered in three chapters, two of them on mitochondria. One would have been sufficient; the longer one (Evans), while initially intimidating, makes informative reading. Another contribution deals with

S&S has the material & methods...

For high density colony hybridization.

The S&S colony hybridization device (MV 082/0) used in conjunction with S&S BA85 NC™ nitrocellulose, optimizes the colony hybridization technique of Grunstein and Hogness. Especially effective for high density screening (up to 90,000 colonies per 82 mm filter), it promotes binding of colony DNA to be filtered and prevents smearing during washing procedures. Current techniques for this procedure, as well as for plaque screening, are described in the pamphlet "Colony Hybridization and Plaque Screening Methods" (Bulletin 366) recently published by S&S. Request your copy today along with descriptive literature on the MV 082/0 (Bulletin 114).

MICROCOMPUTER SOFTWARE FOR SCIENTISTS

DNATOOLS. This is a general purpose program that allows DNA sequence analysis for restriction enzymes, user defined sequences, repeat and inverted repeat sequences as well as comparisons with other sequences. Analysis is performed in real time visual mode. That is you can scroll a DNA sequence across a screen and have the information displayed immediately. The program has many other options.

PUT&GET. This is a general purpose journal reference retrieval program. You enter your references in plain English with no complicated formats. They may be later selected, displayed, printed or stored in a number of unique ways.

Both programs are available for the IBM-PC(PC-DOS, MS-DOS, & CPM86) as well as CPM v2.2 for 8 bit systems. Write for further information, brochure and price list.

MEDICAL SCHOOL DIDN'T PREPARE YOU FOR THE PRACTICE OF COMPUTERS

THAT'S THE REASON FOR M.D. COMPUTING

Medical practice and computer technology go hand-in-hand.

That partnership means progress in patient care –
- Improved diagnostic capabilities
- Enhanced monitoring potential
- Expanded access to current research
- Extended availability of educational materials

That partnership means progress in practice management –
- Greater efficiency in managing patient data
- Increased flexibility in business procedures
- More versatility in practice analysis
- Greater access to financial data

M.D. COMPUTING helps make your computer a partner in the practice of good medicine. It's the professional journal that keeps pace with the needs of your practice. That's because M.D. COMPUTING is written by physicians ... for the physician of today.

The Microbe 1984

Part I: Viruses

Edited by **B.W.J. MAHY** and **J.R. PATTISON**

Part II: Prokaryotes and Eukaryotes

Edited by **D.P. KELLY** and **N.G. CARR**

Celebrating the hundredth meeting of the Society for General Microbiology, some of the world's most eminent microbiologists have been invited to review the present state of microbiology and to look ahead to new developments that the future may hold.

Society for General Microbiology Symposium 36

Part I: *0 521 26056 6* **£30.00 net/$59.50**
Part II: *0 521 26057 4* **£30.00 net/$59.50**

Invertebrate-Microbial Interactions

Edited by **J.N. ANDERSON, A.D.M. RAYNER** and **D.W.H. WALTON**

Contributed by some of the most active researchers currently working in pure and applied biology, the eleven substantial papers in this book explore the striking relationships between invertebrates, fungi and bacteria.

0 521 25395 0 **£40.00 net/$79.50**

Comparative Physiology of Sensory Systems

Edited by **L. BOLIS, R.D. KEYNES** and **S.H.P. MADDRELL**

The papers in this stimulating volume examine in detail the various ways in which different animals obtain and make use of information about their environment through the detection of light, sound and odours.

0 521 25002 1 **£65.00 net/$99.50**

Calculus

Basic Concepts and Applications

ROBERT A. ROSENBAUM and **G.P. JOHNSON**

Equally suited to independent study or use as a course text, this book examines the practical applications of calculus in the social, behavioural, life and physical sciences.

0 521 25012 9 **£12.50 net/$24.95**

Computer Mathematics

D.J. COOKE and **H.E. BEZ**

Assuming no specific knowledge of mathematics, this book provides a firm mathematical basis for the formal study of many topics in computer science. The basic concepts, from sets through a variety of algebraic structures are described, permitting the precise specification and subsequent analysis of many problems in computing.

Cambridge Computer Science Texts 18

0 521 25341 1 **Hard covers £25.00 net/$49.50**
0 521 27324 2 **Paperback £8.95 net/$19.95**

Current Perspectives in Health Computing

Edited by **B.J. KOSTREWSKI**

The 28 papers here chart current computing applications in health care in the United Kingdom. Topics covered include: the application of computing techniques in nursing care, nurse education, patient investigation and monitoring, community medicine, general practice and specialized decision support.

British Computer Society Workshop Series

0 521 26705 6 **£17.50 net/$34.50**

Indirect Imaging

Measurement and processing for indirect imaging

Edited by **J.A. ROBERTS**

This book collects the main papers presented at an international symposium on indirect imaging held in Sydney in late 1983. The topics covered in the 45 papers include: radio telescope, optical and medical imaging, calibration and hardware.

0 521 26282 8 **£27.50 net/$54.50**

Methods in Radiative Transfer

Edited by **WOLFGANG KALKOFEN**

The 15 papers in this volume are concerned with numerical methods for solving transfer problems in optically thick, radiating media. Of interest to researchers in theoretical physics, astrophysics and plasma physics.

0 521 25620 8 **£25.00 net/$49.50**

Now in paperback

Acceptable Risk

BARUCH FISCHHOFF, SARAH LICHTENSTEIN, PAUL SLOVIC, STEPHEN DERBY and **RALPH L. KEENEY**

'How safe is safe enough?' Nuclear power, recombinant DNA, food additives, and the DC-10 are some of the products of technological progress that raise this question. The authors define the question and analyse why acceptable-risk problems are so difficult to resolve.

0 521 27892 9 **£5.95 net/$8.95**

Models of Category Counts

BERNARD FINGLETON

In this textbook, Dr Fingleton describes some techniques centred on the log-linear model of category counts (or contingency tables), from the perspective of the social, behavioural and environmental scientist.

Forthcoming (August)

CAMBRIDGE UNIVERSITY PRESS

The Edinburgh Building, Shaftesbury Road, Cambridge CB2 2RU — 32 East 57th Street, New York, NY 10022

Circle No.05 on Reader Service Card.

yeast killer toxins (Mitchell and Bevans) encoded by duplex RNA. The extensive discussion of yeast mitochondria in the book could be justified by an as yet ill-defined role of these organelles in affecting flocculation, sporulation and gemination as well as sugar fermentation.

The industrial aspects of yeast are covered in contributions dealing with protoplast fusion (Freeman and Peberdy), genetics of wine yeasts (Snow), flocculation (Johnson and Reader) and in an excellent article by Kielland-Brandt and co-workers on genetic approaches (principally their own) to brewing yeast improvement. These chapters reiterate the message that the genetic analysis of industrial yeasts suffers from their poor mating ability, poor sporulation and poor spore viability. Snow's article briefly introduces an approach that is sure to be exploited, namely, the introduction of a heterologous gene (in this case the bacterial *Lactobacillus* gene encoding the malolactate enzyme) into yeast to modify or increase alcoholic fermentation. To this end the recent introduction of bacterial genes into yeast is notable, for example the gene from *Escherichia coli* coding for xylose isomerase which provides an important step in the hydrolysis of the plentiful supply of xylans.

Finally, the volume includes a chapter by Rank and Robertson on the composition of yeast plasma membranes (somewhat out of place in this book) and a broad review of yeast carbohydrate metabolism by Steward and Russell. What is missing is a chapter on recombinant DNA technology and sections with more information on excretion of extracellular enzymes and proteins.

The contributors are principally European with a sprinkling from North America. References are mainly up to 1981, with a few reaching into 1982. Although it is apparent that the genetics of industrial yeasts is just beginning, the chapters dealing with them do bring us up to date on what is known, often reviewing literature that is obscure to most molecular geneticists. And who knows: maybe some industrial yeast will become the S288C of the fermentation industry. □

Julius Marmur is in the Department of Biochemistry at the Albert Einstein College of Medicine, New York.

Second editions

● Volume II, *Animals*, of T.W. Goodwin's *The Biochemistry of the Carotenoids*. (Publisher is Chapman & Hall/Methuen; price is £25, $50.) The second edition of Vol. 1, *Plants*, was reviewed in *Nature* **293**, 494; 1984.

● *Macromolecules*, Vol. 1 *Structure and Properties* and Vol. 2 *Synthesis, Materials, and Technology*, by Hans-Georg Elias. (Publisher is Plenum; prices are Vol. 1 $65, £50, Vol. 2 $95, £73.15.) The new English-language edition is a translation of the German fourth edition. The original English edition was reviewed in *Nature* **270**, 546; 1977.

Junior prometheans

David J. Rose

The Man-Made Sun: The Quest for Fusion Power.
By T.A. Heppenheimer.
Little, Brown: 1984. Pp.347. $19.95.

In King Arthur's legendary domain, the Knights of the Round Table slew dragons and rescued fair maidens; only the pure of heart could hope to glimpse the Holy Grail. Heppenheimer likens the quest for controlled fusion to such an enterprise, but one pursued by more fallible human beings. In a gossipy book, he takes us through many activities and events, mainly in the United States, telling his story as a sort of passion play, even to the extent of including a list of 42 dramatis personae. It is an unbalanced work, divided into 12 relatively separate acts which are often named imaginatively ("Plasmas on the Potomac") but sometimes not so neatly ("Arms and the Man"). This is a nuisance for the reader, because each chapter has no breaks or subheadings of any kind, and nothing much in the way of a summary. An index is included, but no table of contents. Thus it is a hard book to read seriously, despite the conversational style.

Behind the apparent and sometimes real clash of personalities described by Heppenheimer, there were fundamental differences about how controlled fusion research should be done. Consider the course of events in Washington between 1980 and 1982 ("The Face Off"), leading to the resignation of Edwin Kintner, Director of the Office of Magnetic Fusion Energy, which was apparently triggered by the Office of Management and Budget's insistence that $42 million — about 10% of the annual budget — should be shifted from new construction to operations. Although he fails to dig out all of the details, Heppenheimer gets the story mostly right — that the background issue was whether the time had come for proceeding more rapidly with larger test devices (Kintner's view), or whether then-current programmes should be better supported, to lay a stronger foundation for whatever might come (OMB's view).

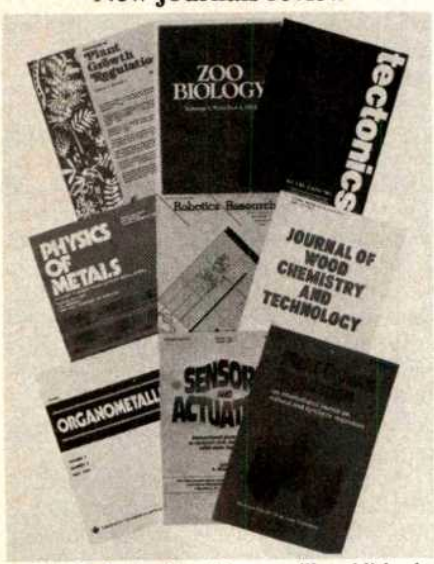
A passionate argument lay behind this affair, which Heppenheimer did not fully uncover in his discussions with any of his 57 interviewees. It was this: what constitutes appropriate science and engineering in the daunting task of confining a nuclear fire with purely ethereal bonds, and getting cheap power out of it. Programmes and budgets refer to milestones, but the only accurate ones are on the road behind; no one knows how many lie ahead or where the end will be.

The search for fusion brought the whole glorious field of plasma physics to its maturity, but all of that science does not necessarily carry us into the world of application. The research devices of today, marvels of engineering in their own right, may not be practicable when scaled up: can the grams of tritium fuel be regenerated and recovered from tons of (probably solid) moderator? Will the vast vacuum wall, thinner in proportion than an egg-shell, survive under neutron irradiation more intense than that in the core of a fission reactor, without leaks, for years? The structure will be radioactive and require remote maintenance more complex than do fission reactors. Other engineering difficulties exist, just as severe. At the end of it all, are fusion reactors likely to be made at a competitive price?

A characteristic of the whole fusion programme has been its dominance by the plasma physicists. But the quest for fusion power involves much more than science alone, and both workers and patrons came to expect too much, too easily, too soon. Robert Hirsch, Director of US Magnetic Fusion from 1972 to 1976 (to whom Heppenheimer devotes an entire chapter), managed to increase the budget from $20–25 million to twenty times that amount, matching the scale of work to the task much better than before. But Hirsch left an unwelcome legacy — time-tables for the development of fusion reactors that presumed a state of scientific and engineering knowledge that just did not exist.

Kintner's agony had its roots in much the same sort of optimism. He advocated a series of ever larger experiments, as engineering test-beds. There were — and are — serious differences of opinion about whether that was the best way to proceed. Some engineering wisdom comes from such billion-dollar attempts, but does it come too narrowly, at too great a price? Other problems need working out more generally, and the answers are essential in helping us to judge the feasibility of fusion before resources become committed to a single giant device.

Heppenheimer devotes two chapters to laser fusion, starting with the late Keeve (Kip) M. Siegel, founder of KMS Fusion, and his chief scientific associate, Keith Brueckner. In the laser approach, a sub-millimetre pellet containing a deuterium-tritium mixture is subjected to a huge laser pulse that blows off the outer layers of the pellet, compresses it and heats it to fusion temperature. That scheme is related to how an H-bomb works. The somewhat delicate point arose whether Brueckner, who had some access to the technology, was using government-financed classified research for private commercial advantage. Apart from covering such tittle-tattle, Heppenheimer discusses this whole approach to fusion optimistically, an attitude that might find its explanation in the list of enthusiasts he interviewed.



This kind of star-wars view of fusion energy (and perhaps of fusion research in general) seems to me to lose sight of the original goal: to provide a rather mundane

but essential service — energy — in as simple ways as are consistent with economic, environmental and social goals. Continuing experimental and analytical studies of laser fusion seem to be raising the technological ante for success faster than budgets, technology, and perhaps even science, can cope.

As to the characters and events themselves, Heppenheimer sometimes tells us too much — nine pages on a fight about whether an advance in achieved plasma energy was to be publicized, for instance. Are we really so interested in the appearance of the last part of Sir Galahad's horse to leave the stable? But in his last chapter, and occasionally elsewhere, Heppenheimer catches the spirit that inspired the pioneers in this enterprise. They were among the most brilliant of scientists, both in the United States and elsewhere, and did what they did because it was, in some deep way, a good thing for society to do. Some of that spirit still exists; without it, the quest will surely fail. □

David J. Rose is a Professor of Nuclear Engineering at the Massachusetts Institute of Technology.

New journals review

On 27 September *Nature* will publish the fourth annual review supplement devoted to science journals.

Criteria for inclusion of a journal in the 1984 issue are that:

(i) the first number appeared, or the journal was retitled, *between June 1982 and May 1983* (the second cut-off date allows at least three issues of a journal to have been published, the minimum number on which a reasonable judgement can be based);

(ii) it is published at least three times a year;

(iii) the main language used is English.

Publishers and learned societies are invited to send *four different issues of each suitable periodical, including the first and most recent numbers* (if from outside the United Kingdom, by air mail) to: The Review Editor, *Nature*, 4 Little Essex Street, London WC2R 3LF, England. Subscription details, if possible for both 1984 and 1985, should be included.

A different sort of Darwinism

J. H. Brooke

Darwin and the Spirit of Man.
By Alister Hardy.
Collins: 1984. Pp.245. £9.95.

SIR Alister Hardy is prominent among those who have argued for "Darwinism with a difference". Whilst acknowledging the creative powers of natural selection, he enshrines innovative behaviour as a distinctive selective force. His argument is that a learnt and beneficial habit can be instrumental in structural selection by favouring *subsequent* genetic change which might reinforce the behavioural novelty. In the approved words of R.F. Ewer: "behaviour will tend to be always one jump ahead of structure and so play a decisive role in the evolutionary process".

From such a possibility, Sir Alister advances the claim that behavioural selection has been one of the "major factors" in the evolution of birds and mammals. His sights are set on what he considers an "intellectual scandal" — the notion that Darwinian evolution can only be construed in materialist and reductionist terms. Using results from his Religious Experience Research Unit, his aim is to present an alternative synthesis which does justice both to the integrity of biological explanation and the reality of religious experience. So urgent a purpose in so distinguished a figure deserves serious consideration.

Informal in style, almost evangelistic in tone, the exposition strives for intellectual unity in a manner which strikes one as more impressionistic than formally rigorous. Even non-specialists may be perplexed by the way Sir Alister structures his alternatives. The reader is asked to choose between a chance mutation or a new habit as the instigator of adaptive change. Sir Alister's heart is with the latter, elevating the conscious, explorative and perceptive aspects of animal behaviour. But may not the choice itself be misleading? If a bird learns a new trick, even how to raid a milk-bottle, the capacity to learn was presumably already there in the gene-complex, having been encouraged by past selection. And if the new behaviour continued to be advantageous, it would presumably be favoured, again by the normal process of selection. Conversely, a mechanism whereby genetic change *subsequently* reinforced a behavioural innovation might invite the objection that it could destroy a useful flexibility of response. The new habit, if genetically and structurally "fixed", might sacrifice versatility for a precarious short-term gain.

A constrictive choice is also presented in the treatment of consciousness: either an extreme reductionism, in which consciousness is epiphenomenal; or a form of psychophysical dualism, affirmed on eminent authority but largely assumed by Sir Alister rather than specifically argued for. Excluded by this dichotomy would be those monistic accounts which treat consciousness as an "emergent" property, associated with a particular degree of material organization, but neither reducible to it nor the product of an elusive spiritual element. It is Sir Alister's view that the spiritual element is not, after all, elusive. It exists in all mankind and may be discerned in numerous reports describing a

Sir Alister Hardy — "Whilst acknowledging the creative powers of natural selection, he enshrines innovative behaviour as a distinctive selective force".

"feeling of receiving help from a power, from Divinity, beyond the self".

The perplexity here is that whilst the author offers a sensitive classification of reported experiences, it is not shown how, from reports alone, one can establish anything further than the point that such feelings of dependence are common. The counterpoise is still that which weighed so heavily with the young Charles Darwin as he studied the natives of Tierra del Fuego: such feelings were apparently not shared by, and therefore not essential to, all humanity. The further suggestion that this sense of drawing upon a power outside the self might have become an energizing force in human evolution, a "something that gave more courage than [men] had ever had before", is not without difficulty. Might that sense of dependence not just as easily encourage passivity as activity? Alternatively, supposing it had gradually been reinforced by its survival value, would that really persuade us that man's spiritual nature had any transcendental significance? But whatever one's response to Sir Alister's confessedly personal view, it is stimulating to engage his own burning questions. □

J.H. Brooke is a Senior Lecturer in History of Science and Principal of Bowland College, University of Lancaster.

THE COMPUTER MODELLING OF MATHEMATICAL REASONING

edited by Alan Bundy
1983, 336pp
Cased: 0.12.141250.4 $33.50/£19.80 (UK only)
Paper: 0.12.141252.0 $15.00/£9.50 (UK only)

Based on existing courses at Edinburgh University, this book fills a niche hitherto ignored by the current textbooks on artificial intelligence. The heart of the text examines both theorem proving and non-theorem proving programs and relates these to mathematics and the process of doing mathematics. The text also discusses the techniques described, and provides, in the appendices, solutions to the problems found throughout the text.

PARSING NATURAL LANGUAGE

edited by Margaret King
1983, 318pp., 0.12.408280.7
$21.00/£13.60 (UK only)

Parsing natural language involves using a computer program to convert an ordinary language like English to some abstract representation of its syntactic or semantic structure. This task is both an intellectual challenge, and a practical necessity as a first step towards question-answering, data base interrogation and machine translation programs. This book compares and contrasts current artificial intelligence approaches to parsing, exploring their relationships to contemporary theories in linguistics. It provides a thorough introduction to this exciting and rapidly developing field.

DISTRIBUTED COMPUTER SYSTEMS

edited by Y. Paker and J-P. Verjus
1983, 318pp., 0.12.543970.9
$27.50/£16.50 (UK only)

Specification and analysis of parallelism in distributed computing systems is covered in Part One of this book. Part Two examines language aspects: Pascal-m, Path Pascal and Mascot. The final section is concerned with application and implementation and includes papers on major research projects such as CHORUS (including the "actor" concept), MICROSS (a graphics aided tool for DCS), and an example of local area network for industrial applications.

A Volume in the APIC Series

FORTRAN OPTIMIZATION

Michael Metcalf
1982, 256pp., 0.12.492480.8
$24.00/£13.00 (UK only)

This book deals, for the first time, with the whole topic of FORTRAN optimization, explaining the relevant hardware and modern compiling techniques before going systematically through the procedures which may be applied to optimize source code. Attention is given to distinguishing the types of compilers used. All IBM and CDC compilers are treated in detail. The use of super-computers is introduced, and the question of program portability and the future shape of FORTRAN are covered.

A Volume in the NOTES AND REPORTS IN COMPUTER SCIENCE AND APPLIED MATHEMATICS Series

LABORATORY MINICOMPUTING

John R. Bourne
1981, x + 298pp., 0.12.119080.3
$29.50/£20.60 (UK only)

From the Preface:
While general information about computer programming is abundantly available, most users of laboratory minicomputers will find it more difficult to secure information specifically tailored to their needs... The purpose of this book is to provide such information. Background material is provided to allow the reader with little or no knowledge of minicomputers to learn to successfully use minicomputers for a variety of laboratory data acquisition and analysis purposes.

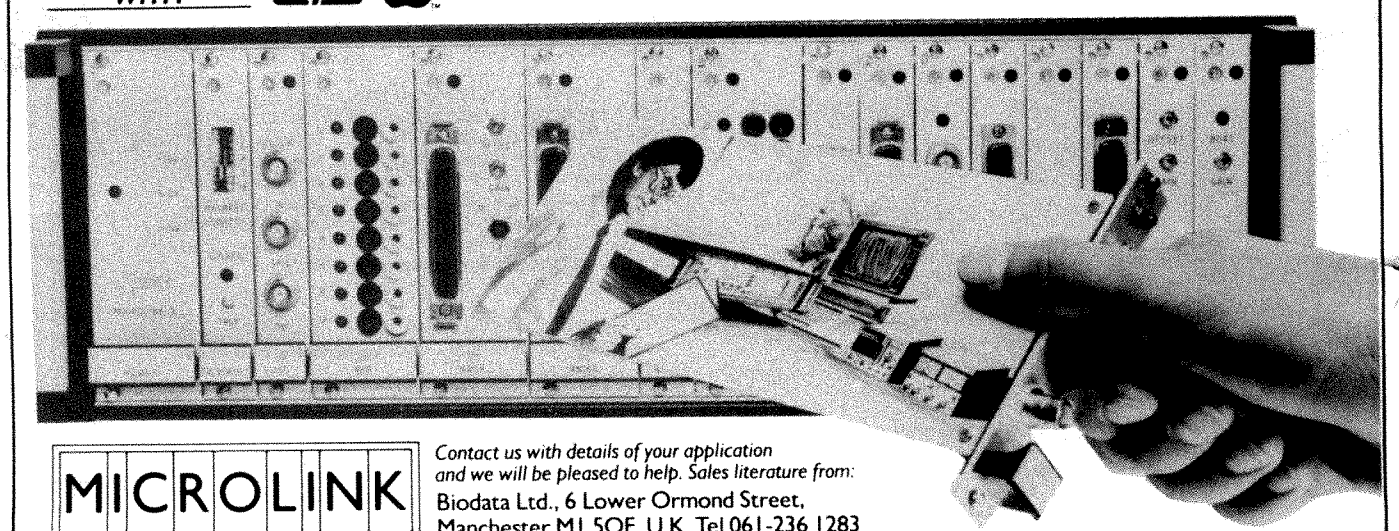
MICROLINK - THE MOST FLEXIBLE COMPUTER INTERFACE



Full modularity MICROLINK is a fully modular laboratory interface designed and constructed to the highest professional standards. MICROLINK uses the IEEE-488 bus, the only real choice for instrumentation systems.

Superlative specification An unsurpassed range of 30 modules including analogue and digital inputs/outputs, timers, counters, RS-232 and thermocouple inputs, allows you to connect almost any instrument to your computer. Data transfer rates of upto 50 Kbytes per sec. are achievable and upto 256 analogue inputs can be accepted.

Full software support Programming manuals are available for most computers with IEEE-488 facilities. Sample programs are provided in BASIC so that you can get your measurement/ control system running with minimum delay.

Universal application MICROLINK has been used in environments as varied as North Sea oil production platforms and hospital neurological units, in applications such as: data logging, experimental monitoring and control, environmental monitoring, automatic test and high speed data acquisition.

Automation is just beginning

The laboratory application of computers is being extended rapidly, but there is some way to go before the penetration of these machines is as complete as, say, that of the Bunsen burner.

A FEW years from now, the heading on these pages will be entirely inappropriate. The idea that the use of computers in laboratories is sufficiently novel to be remarked upon will have ceased entirely to be noteworthy, just as it would now seem strange to assemble a few pages of this journal under the heading "oscilloscopes in the laboratory". So charitable readers are invited to regard the pages that follow as a reminder that the present is a transitional period, one in which it is not yet second nature for experimentalists and theorists alike to use all the tools now potentially at their disposal.

It is also worth remarking that the present hectic period during which the laboratory computer is being made familiar has its roots in a period which long predates the development of electronic computing machinery. One of the obvious illustrations of this truth is in the development early this century by C.T.R. Wilson of the cloud chamber, first for stimulating processes occurring in the atmosphere, later for the recording of cosmic ray particles by the trail of droplets produced in a supersaturated vapour. The first studies of cosmic rays were necessarily made with cloud chambers whose expansion (to give supersaturation) was carried out at random. But the technique became productive only when, in the 1920s, cloud chambers could be made to record events only when the chance of something interesting being observed was high.

The (Geiger) counter-controlled cloud chambers of those days are forerunners of the computer-controlled experimental rigs that are now commonplace in many important ways, but not least because they stimulated the development (with thermionic valves or tubes) of the logic circuits now embodied by the thousands in microprocessors. Over half a century, the practice of particle physics has been inextricably bound up with the development of electronic techniques for making sure that observations are made only when it is profitable to do so. And while the techniques have now spread to a host of other fields in which the objective is to record transitory phenomena, accelerator physics remains the citadel of the selfconscious practice of selecting from a mass of naturally arising happenings only those about which observational data are likely to be useful.

Computer-controlled experiment has the virtue of economizing in effort in the way most likely to be productive — by the avoidance of unwanted data. This is the spirit in which, in many biological applications (and more generally), it is possible to record data only for as long as necessary to provide some predetermined degree of statistical certainty. The prerequisite of such procedures is that there should be a computing facility "on-line" with the data-gathering equipment, carrying out an analysis as the experiments proceeds. Again, inevitably, the accelerator people have blazed a trail which everybody will soon be compelled to follow. For the collection of needless data is not merely inelegant but an encumbrance, a distraction. Even now, however, the point is not sufficiently forcefully made in teaching laboratories.

The notion that computers in one form or another have an important part to play in the collection ("logging") and analysis of data is, by comparison, more readily accepted. What seems to be less widely appreciated is that there are already a great many kinds of investigations now commonly undertaken that would be beyond the scope (and stamina) of people without the assistance of computing machinery. Particle physics has again been the pathfinder in this trend, with its techniques for the recording of tracks (or points along the tracks) left by particles in detectors of various kinds, and for their subsequent automatic analysis.

Inevitably, this practice has spread like wildfire. Deep seismic refraction, both in the exploration for petroleum and in geophysical investigations, generates such masses of data that only computer recording and analysis is feasible. The identification as well as the measurement of stellar and galactic objects on photographic plates collected by astronomers is similarly a way of carrying out tasks that would otherwise be impracticable. And even where the quantities of data are not nearly as overwhelming, there remains the possibility that they will not be fully interpreted because the investigator has not the stomach for the task or, more charitably, takes the view that his priorities lie elsewhere. Yet even in this uncontroversial field, where the value and the objectivity of automatic data analysis is generally accepted, teaching laboratories are not nearly as well equipped as they might be.

The application of computers as means of retrieving data is, by comparison, commonly undervalued. Many people have found the widely available bibliographical databases less than a substitute for the professional literature. And it is true that many of these systems are needlessly wooden and inflexible. There may be more promise in the schemes (some of which are referred to in the pages that follow) that assist people to construct their own individual databases, for mnemonics are almost certain to be more "friendly" (in the computer jargon) than substitutes for one's memory.

The use of databases simply for the recognition of meaningful portions of the nucleotide sequences of DNA which have become a common feature of the literature is perhaps the most telling illustration. The plain truth is that it is almost conceptually impossible for a person to compare the sequence of some nucleotide sequence he has constructed with a library of known gene sequences so as to pick out those which most closely resemble each other. Not so long ago, an author of an article submitted for publication was much chagrined that a referee with access to a better computer program was able to spot a similarity that had previously gone unrecognized. But this is only one set of circumstances in many where the full power of computer retrieval remains to be recognized. Rivalry between laboratories will no doubt bring other cases to light.

But none of this, it will be remarked, bears on what must seem the most obvious application of computers in the laboratory — the accomplishment of mathematical tasks that would otherwise be beyond the scope of ordinary people. The use of powerful computers for the simulation of, say, the evolution of weather systems requires no special justification, but the huge installations by which these tasks are accomplished are (and are likely to remain) the exceptions, not the rule.

More interesting are the applications of computer programs to ordinary tedious tasks of algebraic analysis, still regarded as a kind of frivolity or luxury, and to fields in which the underlying characteristics of a mathematical process would not otherwise be apparent. Who would at this stage claim that the importance of chaotic (or "deterministically random") phenomena would have been widely recognized without the computer simulations of the process that are now commonplace? Or that the study of fractal systems could have been accomplished analytically if only mathematicians were less idle? □

Computers in books

Microcomputing in biology

A.N. Barrett

GIVEN the shortage of suitable software for analysing biological data by microcomputer, the publication of books containing methods and programs for that purpose is generally all to the good.

One recent book of this type is *Statistics and Numerical Methods in BASIC for Biologists,* written by J.D. Lee and T.D. Lee and published by Van Nostrand Reinhold (hbk £14.95, $32.50; pbk £7.75). The authors include methods for determining means and standard deviations, chi-squared tests, various correlation coefficients, linear regression and curve-fitting. There are also two chapters on the biological applications of statistics: one on assays, the other on linear regression techniques applied to bacterial growth data.

Accompanying the methods are some 20 programs, written in elementary BASIC, which are highly suitable for laboratory use. The programs are well structured and incorporate numerous checks against incorrect or pathological data. Documentation is provided with the programs, enabling the user to follow easily the program structures, and sample data is available for users to test the programs on their own computer. One price of the robustness of the programs, however, is that they are considerably larger than similar programs performing the same calculations. And to ease typing problems, it would be useful if the programs were available on a floppy disk for the Apple and BBC microcomputers.

A book with similar statistical content is *BASIC Microcomputing and Biostatistics* by Donald W. Rogers (Humana; $39.50 (US), $49.50 (elsewhere)). The aim of the book is to teach essential programming skills, using BASIC, and to provide a range of statistical and mathematical techniques for the analysis of data in the physical and life sciences (including medicine).

The book starts with a rather brief discussion of computing and BASIC, with three simple programs illustrating certain BASIC functions. The next seven chapters deal with a variety of standard statistical techniques and also provide simple programs to illustrate the application of the techniques to limited data sets. The statistical methods introduced cover the understanding of experimental errors and the computation of means and averages, and the determination of probability distributions together with the use of the Poisson and Normal distributions. A chapter is also included on the application of the chi-squared test and Student's *t*-test. Finally, least squares are explained, as well as the fitting of nonlinear curves and the solution to simultaneous equations.

From the point of view of the laboratory scientist, one of the limitations of Rogers's book is that many of the programs are unsuitable in their present form for analysis of experimental data. The curve-fitting program, for example, only extends to a second degree curve and several of the earlier programs are restricted to the determination of properties of groups of five numbers. The principles used do not easily lend themselves to extension of the programs to handling large data sets and as such are of limited value except for teaching. In this context, however, the book achieves many of its stated aims; a lot of examples are provided and the programs are well supported by background information.

In contrast to the preceding two books, James D. Spain's *BASIC Microcomputer Models in Biology* (Addison-Wesley; $34.95, £22.10) contains few programs and concentrates on providing flowcharts to accompany the methods from which the readers themselves can develop programs. Several useful programs in BASIC are available, however — for curve-fitting, polynomial fitting, normal distributions, queuing simulation and graph plotting — either as listings contained in an appendix or on a floppy disk (price $50). The programs run on either the Apple II or TRS-80 computers. The appendix also includes an introduction to programming in BASIC.

The main text is divided into three parts. The first deals with simple equations that model single biological systems or system components such as exponential growth and enzyme saturation. The second is concerned with deterministic models of multicomponent systems and includes, for example, chapters on biochemical reaction kinetics, dynamics of homogeneous populations of organisms, models of microbial growth and simulations of population genetics. The final part deals with the effects of random processes on biological systems, with special attention being paid to sampling processes, random walks and queuing.

As a means of introducing both students and practitioners of biology to theoretical methods and their applications, Spain's book fulfils a useful purpose. Its structure will appeal in particular to those with sufficient programming skills to translate the flowcharts into working programs.

Finally, *Microcomputers and Physiological Simulation* by James E. Randall (Addison-Wesley; $27.95, £14.50) is a softback aimed at providing an introduction to microcomputers and their use in the mathematical simulation of physiological processes.

The first five of the 14 chapters present a discussion on both hardware and software, and include accounts of microcomputer components, and operating system and programming languages, together with graphics facilities for the TRS-80 and the Apple II. Each chapter concludes with a list of addresses of manufacturers of both hardware and software, where appropriate, and with references to relevant journals.

For a book dealing with techniques of mathematical simulation, surprisingly little background mathematics is included. Instead, the author concentrates on providing BASIC (Apple) programs encapsulating the relevant mathematical equations necessary for the simulations and refers the reader elsewhere for the supporting theory. The complexity of the programs varies with the particular application (axon potentials, cardiac action potentials, distortion of physiological waveforms and the glucose tolerance test are among those covered).

Randall's book clearly demonstrates that a variety of physiological processes can be successfully simulated on the microcomputer. It should be of interest to advanced students and physiologists with interests in modelling. □

A.N. Barrett is in the Computing Laboratory at the National Institute for Medical Research, London.

Computers and genes

E.G. Richards

The Applications of Computers to Research on Nucleic Acids II, Parts 1 and 2.
Edited by D. Söll and R.J. Roberts.
IRL Press: 1984. Pp.856. Pbk £30, $60.
Time Warps, String Edits and Macromolecules: The Theory and Practice of Sequence Comparison.
Edited by D. Sankoff and J.B. Kruskal.
Addison-Wesley: 1984. Pp. 382. $28.95, £24.60.

THERE are over one-and-a-half million bases in the latest edition of the EMBL nucleotide sequence library and somewhat more scattered through the literature. If printed, they would comfortably fill the two volumes edited by Söll and Roberts and totally bemuse anyone who opened the pages of such a book. It is then no small wonder that the writing of computer programs to aid the construction and digestion of nucleic acid sequences is a growth industry. The two volumes were originally published as Volume 12, Number 1 of the journal *Nucleic Acids Research* in January of this year. A similar work, half the size, was published in January 1982, giving us a doubling time of two years.

The three parts of the latest volumes are devoted to main-frame computers, mini-

computers and microcomputers. The 79 papers describe programs and systems which range from the grandiose to the trivial. Several of the papers describe large menu-driven systems for processing sequences, including printing out sequences in various formats, translating them into amino acid sequences and searching for restriction sites to mention but a few of the options. Other contributions are devoted to more specialized tasks, such as working out restriction maps, ascertaining the homology between sequences, determining the most stable base-pairing scheme in an RNA chain, calculating the molecular size of fragments observed in polyacrylamide gels and even designing your experiment for you. There is only one paper devoted to the graphic display of three-dimensional structures; this is notable for being implemented on a microcomputer.

Molecular biologists engaged in producing nucleic acid sequences or cogitating on their significance are likely to find something of interest in the two books. It may be that the author will send them a listing when asked (some offer so to do, others are silent on this point), that the program is written in a language and dialect familiar to their local computer, and that appropriate hardware is available. If all this is so, such researchers may be saved hours of work reinventing the wheel. But it is unclear whether the programs themselves have been verified in any way, and hard to tell how robust they are against misuse or how easy they are to use.

Most of the programs concerned with homology and structure prediction are based on the dynamic programming method discovered, apparently simultaneously, by several workers in the 1970s. This method, based on an argument by induction for ascertaining the minimum number of insertions, deletions or changes required to transform one sequence into another, is well described in *Time Warps, String Edits and Macromolecules.*

In this book, various contributors explain how almost identical problems arise in several disparate fields, including speech recognition. Here the pressure wave corresponding to the utterance of a word is sampled at discrete times and a resulting vector compared with that of a standard word. Since people vary in the rate at which they speak, the sampling rate must be varied in some way; that is, time must be warped.

Much of Sankoff and Kruskal's volume should be accessible to molecular biologists interested in the intricacies of sequence comparisons and similar problems, and should serve a useful role in acquainting them with the state of play in this area. Other parts are more mathematical and thus more suitable for the computer specialist. □

E.G. Richards is Senior Lecturer in Biophysics at King's College, University of London.

How to crunch your numbers

Gordon C.K. Roberts

Biodata Handling with Microcomputers.
By R.B. Barlow.
Elsevier Biosoft, 68 Hills Road, Cambridge CB2 1LA, UK: 1983. Pp.261. £18, $30. Disks £30, $50.

EVEN the least expensive "home computers" are capable of carrying out all the statistical analysis that most biologists will require — and usually before the answer can be obtained from the computer centre. The main obstacle to practical realization of this is, of course, the limited availability of appropriate programs. Behind the somewhat mysterious title (what *is* "biodata"?), this book goes a considerable way towards meeting the need. It contains some 50 programs which cover most simple statistical procedures, from standard deviations and significance tests through analysis of variance to linear and non-linear (iterative) regression.

The book contains listings of the programs (in Commodore PET BASIC), reproduced from a dot matrix printer, while the text is reproduced from typescript — both are entirely legible, although the multi-statement lines and lack of indenting make the programs harder to follow than they need be. White space is prominent, since many pages are under two-thirds full, and there are several rather un-funny cartoons.

Each program is accompanied by a brief but generally adequate commentary describing what is going on, and in many cases also by an even briefer outline of the underlying mathematics. Beginners may need a statistical text to amplify some of the explanations if, as the author hopes, they wish not only to use this book as a "toolkit" but also to understand how the tools work. In addition each program has a sample output, the examples being drawn primarily from pharmacology.

The programs cover clearly the most widely used statistical procedures, and are available on disk for Commodore PET, Apple and Commodore 64 computers. The combination of disk and book certainly adds up to a useful elementary statistical package. □

Pascal in practice

Graham H. Kirby

Pascal Applications for the Sciences: A Self-Teaching Guide.
By Richard E. Crandall.
Wiley: 1984. Pp.246. Pbk £13.90, $16.95.

THE number of textbooks which deal with computer programming in Pascal is very large and still increasing. So it is refreshing to find that Richard Crandall's book concentrates on *applying* the language. The author's aim was to provide a text which would enable students of mathematics, physics, chemistry and biology to learn scientific programming in Pascal. Applications in each of these specific subjects follow a general introduction to simple numerical programming.

The book is a self-teaching guide, consisting of text, exercises, answers, more text and so on. Some exercises involve modification of the many programs presented in the text whilst others are distinctly ambitious. Many answers are short comments and hints rather than code. One of the good features is the emphasis on graphics to display computed results, rather than on the printing of tables of numbers, and a microcomputer with graphics facilities and Pascal would provide the ideal basis from which to benefit from the book. Also commendable is the provision of source code for libraries of Pascal procedures covering graphics, matrix handling, statistics and specialized mathematical functions. Of course, the graphics library is hardware specific (for Tektronix 4012 terminals).

A book such as this, modestly-priced and devoted to applications, has insufficient space to introduce the language itself. Readers will require either a prior knowledge or an introductory textbook on Pascal programming. Without one or the other, the benefits of Pascal will not be appreciated since Crandall has concentrated entirely on the mathematical modelling type of application using simple numerical and statistical techniques. This is a pity because the full power of Pascal is not demonstrated — I noted very few occurrences of the type *char*, only one of records (for complex numbers) and of the case statement, and none of pointer types. The programs could be re-written in FORTRAN or BASIC with few changes.

Science students will find this book helpful in learning to write simple Pascal programs for applications in their subject area. I hope they go on to learn more of the facilities in Pascal; many scientific applications do require data structures other than arrays and types other than integer and real. □

Graham H. Kirby is a Lecturer in Computer Studies at the University of Hull.

● Reston/Prentice-Hall have just published *Scientific Pascal* by Harley Flanders, a book written specifically to teach practical programming to scientists and students of science. Price is hbk $29.95, £28.45; pbk $21.95, £20.85.

Sorts of references

K.V. Roberts

PAPERBASE: A Computerized Personal Database for Scientists.
By Anthony Durham.
Wight Scientific, 44 Roan St, London SE10 9JT. Booklet, pp.31, £25, $50 (airmail postage included) for institutional use; £10, $20 for personal use. Diskettes available for various computers, £50, $100 (booklet included).

PAPERBASE is a BASIC package for constructing and interrogating a database of references. It normally uses a microcomputer with diskette drives, screen, keyboard, printer, BASIC interpreter and word-processing program, although it can run on larger or smaller systems. I tested it on an IBM PC-XT and found the increase of speed provided by a Winchester disk and the BASIC compiler to be an advantage, although it is still a very useful system without these facilities.

References and keywords are input using program STORE: it is important to get the format correct, but this is not difficult and one can edit the ASCII output file later (for example to add new keywords). ORDER sorts alphabetically by first authors and an on-line search on logical combinations of expressions is carried out by SEARCH, producing a file containing those references that meet the given criteria. References are converted to the format required by a particular journal by LAYOUT, using word-processing facilities such as boldface and underlining where appropriate. The user may need to develop his own format code since journal practice differs so widely, but examples are given and it should not take long to master the rules. Finally, HUNTER scans through an ASCII file — for example a typescript produced on a word-processor — to report the references that it finds.

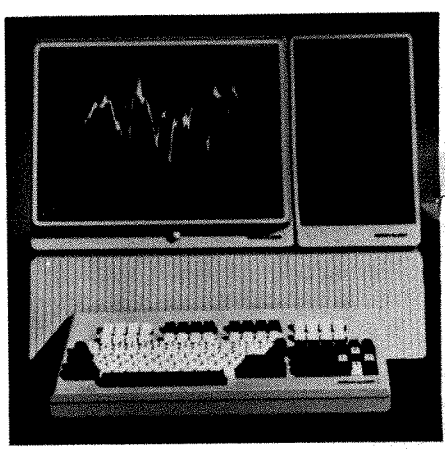
The BASIC program may have to be modified before use, depending on the computer. For the IBM PC no changes were necessary and PAPERBASE ran straightaway. However, the code is well documented in the booklet, and advice is given on how to make changes should these be needed. Users may also wish to extend the programs to meet additional requirements or to build them into larger systems; I found it helpful to modify SEARCH so that it did not distinguish between upper and lower case, and this was readily done with a few BASIC statements although it somewhat slowed down the search.

Altogether PAPERBASE is a well-engineered piece of software. It should find wide use throughout the scientific community. □

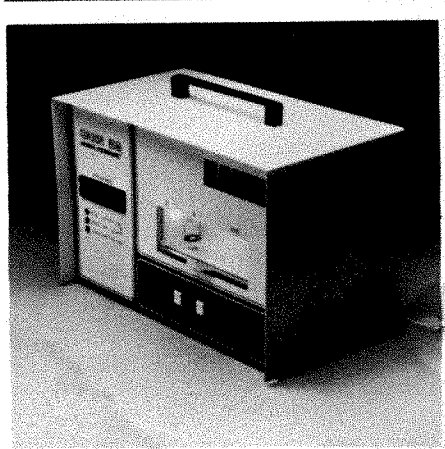
K. V. Roberts is Head of the Theoretical Physics Division at the Culham Laboratory of the UKAEA, Abingdon, Oxfordshire.

New computer products

By using the Reader Service Card, details of twenty-one new computer based products can be obtained.

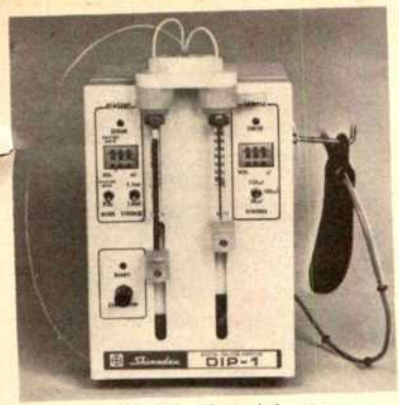


● The Series 7000 professional computers from Perkin-Elmer are advanced microcomputer data processing systems specifically for laboratory applications. Two models are available: the PE 7500 and PE 7300, capable of both analytical and management functions. In an integrated workstation, a Series 7000 computer is complete with a detachable keyboard, colour or monochrome graphics display, Winchester and floppy disk drives. The electronics module contains a Motorola 68000 16-bit microprocessor which has 32-bit internal data pathways and can address up to 16 megabytes of random access memory (RAM). A Series 7000 computer contains 640 kilobytes of RAM as standard. The internal memory can be expanded by one megabyte by the addition of an internal expansion board. Perkin-Elmer produces applications software for instrument control, data collection, data storage and graphical manipulation for infrared, ultraviolet/visible, fluorescence and atomic absorption spectroscopy, gas and liquid chromatography and thermal analysis. Users can write their own programs in BASIC and FORTRAN.
Circle No. 100 on Reader Service Card.



● Beckman Instruments' SYNLIB is a computer software system for the creation, maintenance and search of chemical reaction data files. The SYNLIB program has been designed specifically for synthetic chemists involved in the manufacture of organic chemistry products, pharmaceuticals and chemical specialty products. The SYNLIB system is distributed with a database of over 12,000 chemical reactions abstracted from the scientific literature. A continuing database updating service is available, and users may easily establish, maintain and search their own chemical databases containing chemistries which are of local interest.
Circle No. 101 on Reader Service Card.

● TUTSIM is a program for the simulation of contaminous dynamic systems, and is now available in a short form which is suitable for evaluation, demonstration and instructional study. TUTSIM is available for IBM XT/PC, and PC jr, Apple II and some CP/M machines. The TUTSIM program was created by the Twente University of Technology in the Netherlands. It is a block diagram orientated program which produces both numeric and graphics output. Disciplines to which TUTSIM is applicable include physiological and biological model studies, thermodynamics and fluid dynamics and econometrics and sociological systems. TUTSIM is available in the United States from the Applied i company of the Palo Alto, California.
Circle No. 102 on Reader Service Card.



● The Cahn Model 28 microbalance and C-29 ultra-microbalance now include as standard equipment the RS-232 interface for printers, computers and other peripheral equipment. Weighing to a precision of 0.1 microgram, Cahn Series 20 microbalances offer automatic calibration, wide dynamic ranges, remote weighting in glove boxes, hot boxes or environmental chambers. Operation is simple, as no internal weights or special set-ups procedures are required. Both the Model 28 and 29 balances are portable. The microprocessor controlled microbalances have capacities of 3.5 grams.
Circle No. 103 on Reader Service Card.

● The LABSAM/3350 is a Hewlett-Packard software package designed to manage and organize the flow of samples through the laboratory. LABSAM's primary functions include sample log-in, result acquisition, validation and reporting. LABSAM is designed for use with the HP 3357 Laboratory Automation System which features: disk storage up to 1 gigabyte; BASIC, FORTRAN and PASCAL languages; a wide range of terminals and printers; and a large selection of graphics devices.
Circle No. 104 on Reader Service Card.

Perkin Elmer's professional computer (top) and the Cahn 29 balance

The Shimadzu DIP-1 diluter/pipetter

● A new data and chromatography control system allows chromatographers to set up HPLC methods in plain English and to control all system functions from one keyboard. The Waters 840 control station incorporates the Digital Professional 350 computer with Waters Expert chromatography software. The separation can be followed while it happens with real-time plotting on the screen, or the system can gather raw data from an analysis while the screen is used to perform other tasks. A high-speed, high capacity Winchester hard disk stores methods and up to one month of continuous raw data from up to four detectors. Dual floppy disks provide long-term storage of methods and data and allow easy recall for reprocessing or comparative analysis. In addition, integration methods can be changed in seconds to optimize data reduction, or the Waters SCANNER routine can be used to reprocess individual peaks at the touch of a button.

Circle No. 105 on Reader Service Card.

● Technical Database Services (TDS) of New York is offering a new search and retrieval service for the Log P Database. Subscribers at remote computer terminals can search over 25,000 records containing partition coefficients and related information for over 12,000 organic compounds in approximately 300 solvents. This compilation of Log P data results from a cooperation between the Pomona College Medical Chemistry Project and scientists throughout the world. The database, now in its fourteenth year, is updated semi-annually and increases by approximately 2,500 records each year.

Circle No. 106 on Reader Service Card.

● The new D470 titration kit from Radiometer is a complete package connecting Radiometer titration equipment to a Hewlett-Packard HP-85 personal computer. The fully documented standard tape is pre-programmed to perform automatic titrations with the simplest possible operation; only 4 soft keys have to be operated for routine titration. Equivalence points are automatically detected as the inflection points of the titration curve. The titration results and curve are displayed on the screen of the HP-85 and can be plotted by the built-in printer/plotter.

Circle No. 107 on Reader Service Card.

● The Shimadzu DIP-1 is a simple-to use computer controlled dilluter/pipetter. Just set the dilution ratio on the digital dial, selectable in 18 steps of 2 to 100, and it will accurately dilute the sample at that ratio on dispensing. The unit can also be used for dispensing, sampling, and diluting-dispensing. When only a reagent is to be dispensed, if the set volume is larger than the full stroke volume of the syringe it will automatically repeat to provide the desired volume up to 9.99ml. When an extremely small sample is to be taken (5 to 25μl) the volume required is set on the digital dial, and the tip of the nozzle placed in the sample. At one press of the "start" button the volume of the sample will be drawn up, and when pressed again the sample will be expelled into a container. When used for diluting-dispensing, the volumes of reagent and sample are set, and all the rest is performed at a press of the "start" button.

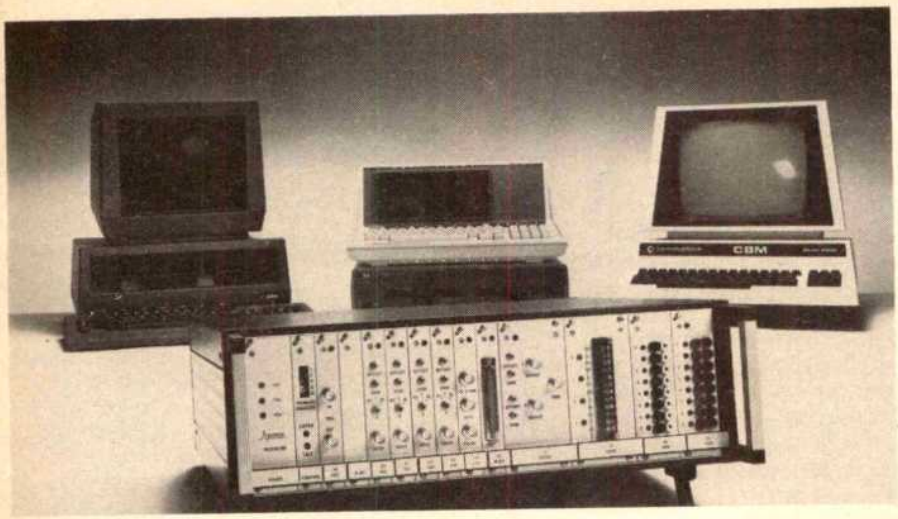
Circle No. 108 on Reader Service Card.

● AUTOSCAN, from Spectra-Physics is a BASIC program on a PROM chip for automatic stop-flow peak scanning, absorbance ratio determinations, and time-programmable wavelength changes. The program is intended for use with the SP8440 UV/VIS variable wavelength detector in conjunction with Spectra-Physics HPLC systems and the SP4200 computing integrator. In addition to reporting absorbence ratios and plotting of spectra, AUTOSCAN allows for completely unattended operation since the HLC pump start/stop functions are integrated into the program software. The chip plugs directly into the memory board of the SP4200 computing integrator and is the latest addition to Spectra-Physics Special Purpose Software Programs $(SP)^3$ series. This firmware-based system eliminates the need for loading programs from auxiliary storage devices such as disk or magnetic tape.

Circle No. 109 on Reader Service Card.

● A Thermex interface converts Apple II Plus or Apple IIe computer into an automatic-printing 16 channel thermometer. The interface uses J, K or T thermocouples as sensor, and resolution in the biological temperature range is 0.1°C. At other temperature ranges an accuracy of 0.28% full-scale is achieved using individually calibrated thermocouples. A special calibration program is available, allowing the user to calibrate and linearize thermocouple probes in any desired range. Thermex, available from Columbus Instruments of Ohio, has built-in cold junction compensation. Biological probes for rectal, intravenous and implantable applications are available for animal use. A video monitor displays current temperatures in all channels. Data are also periodically printed and saved on disk at selected intervals. An optional data-transfer package allows information to be transferred from disk to files to a host computer via an RS-232 interface.

Circle No. 110 on Reader Service Card.



The Radiometer D470 (top), the AMICA titration system (centre) and a thermometer for use with Apple computers

● Routine photometric measurements, potentiometric titrations of all kinds and photometric titrations can be performed with the computer controlled AMICA system from Hamilton. The titrimetric methods used include acid-base titrations, redox titrations, titrations in non-aqueous media photometric titrations with or without indicator and complexometric titrations. Because of its modular design an AMICA system can be adapted to the individual needs of any analytical control laboratory, whether the need is a small number of samples and frequent change of method, on many samples for few models.

Circle No. 111 on Reader Service Card.

● ELISA-CALC, available from Comple-Software of Iowa City, is designed to transfer data from an automated ELISA plate reader to a personal computer. The data are then saved on floppy diskettes; each diskette will hold data from more than 500 plates. ELISA-CALC allows the user to enter a custom plate "map" defining the contents of each well on the ELISA plates; this map is saved on the diskette so that it can be used indefinitely. The computer displays graphically each standard curve, either as a semi-log or as a log-log plot. It then allows the user to pick the appropriate points to produce the best line to fit each curve. Then it calculates each unknown on the plate using the appropriate standard designated on the plate map. It allows the user to calculate ELISA data immediately after the plate has been read, spending two or three minutes rather than hours per plate. ELISA-CALC is available to run with automated ELISA readers sold by Bio-Tek Instruments, Inc., Dynatech Laboratories, Inc. and Flow Laboratories. Inc.

Circle No. 112 on Reader Service Card.

Biodata's Microlink interfacing system

● The CmC BUSSter RGA is a microprocessor-based interface designed to give RS-232 computers and terminals the ability to function as IEEE-488 controllers. Up to 15 individually addressed IEEE-488 devices can be connected through the BUSSter RGA to one RS-232 port. The BUSSter RGA serial port features include switch-selectable band rates (300 to 19,200), parity and word length. It can be configured for talk and listen commands for any IEEE-4888 address or secondary address from 0 to 31. Multiple devices can be addressed at the same time. The RGA is also compatible with service request, serial poll, parallel poll, remote/local, local lockout, device clear, and device trigger interface functions.

Circle No. 113 on Reader Service Card.

● Coulter Electronics have now introduced into Britain the Micromeritics computer-controlled DigiSorb 2600 gas adsorption analyser. This completely automated physisorption instrument may be used with a wide variety of adsorbates to determine surface area, pore volume, pore size and pore area. Features include operator selectable parameters, automatic pressure transducer calibration, sample outgassing to 550°C and a large liquid nitrogen reservoir. Unattended operation is possible for up to 4 days. Automatic data and graphic presentations are printed for up to five samples.

Circle No. 114 on Reader Service Card.

● The Philips Automated Laboratory Management (PALM) system can tackle both sample analysis control and industrial proces/quality assurance. A typical PALM installation might include automatic sample preparation machines with conveyor links to a laboratory or directly to an X-ray spectrometer. The PALM system is principally intended for use in conjunction with Philips equipment, but instrumentation other than Philips may be used. Results from various sources can be merged to give a complete analytical report with a minimum of delay, via terminals or printers in the laboratory or at remote locations.

Circle No. 115 on Reader Service Card.

● Integration of chromatography data can be achieved swiftly using Autovideogration software for the Apple IIe or II+ computer. The program, from Heyden Datasystems, can be used with thin layer chromatography as well as being applicable to many GC and LC needs, especially when fewer than 20 peaks are being measured. Raw data may be viewed on the screen with scale expansion. Baseline position is under user control and integration may be automatic, manual or peak by peak. Results are tabulated with percentage peak areas, and all data can be stored to disk for subsequent examination.

Circle No. 116 on Reader Service Card.

● Two new features for GenBank, the genetic sequence data bank from Bolt Beranek and Newman Inc. (BBN), make for improved accessibility. A new interface allows the user to access GenBank data via a short series of menus and dialogues, and access is now possible through Telenet, an internationally available communications network. This eliminates the need for dialing into the system via long-distance telephone lines. GenBank, developed by BBN and Los Alamos National Laboratory for the National Institute of General Medical Sciences of the National Institutes of Health, is a repository of all published nucleic acid sequences greater than 50 nucleotides in length, catalogued and annotated for sites of biological interest.

Circle No. 117 on Reader Service Card.

● The publishing company Elsevier has introduced a range of scientific software with source code listings. The programs now available are: REVALUE: a software package to calculate reference intervals from total hospital patients laboratory date (for HP 85, PDP 11/23, PDP 11/45, PDP 11/70, VAX 11/780); BALANCE: a program to compare two series of measurements (Apple, IBM PC); and INSTRUMENTUNE-UP: an experimental optimization program, which helps the user to improve the performance of common scientific laboratory instruments (Apple, IBM PC).

Circle No. 118 on Reader Service Card.

● Electroplan of Royston, Herts, specializes in interfacing analog and digital signals from scientific instrumentation and laboratory experiments into many types of desk-top microcomputers. Systems available include Biodata's Microlink, which consists of a card frame into which modules are slotted to build up a flexible interfacing unit. Microlink connects to computers using the standard IEEE-488 interface, and interface cards and programming software are available for use with Hewlett-Packard, IBM, BBC, Commodore CBM PET, ACT Sirius and Apple computers. Electroplan is also UK distributor for Tecmar Labmaster and Labtender, which are data acquisition products designed to plug directly into the IBM-PC and other compatible computers. These are multifunction cards, offering 16 analog inputs, a 24-line general purpose digital input/output interface, and 5 event counters and timers on one convenient plug-in.

Circle No. 119 on Reader Service Card.

● Beckman's products for laboratory information processing can be divided into three categories: data acquisition; data analysis; and sample, test and method and result management. Data acquisition includes intelligent instruments, RS-232 interfaces, standard information protocols and interfaces for other manufacturers' instruments. Data analysis includes application-specific software packages for such applications as tablet dissolution, kinetics, content uniformity and gel scanning analysis. Sample, test and method and result management includes large-scale systems for automating entire laboratories. Beckman systems interface directly to all laboratory instruments from all major manufacturers. Both instruments and accessories can be controlled. The systems are directed by laboratory-developed methods. MK 4 and MK 5 Digimetry instrument couplers provide for interfaces with analog instruments, as well as instruments without an RS-232 interface or standard information protocol. Data acquisition programs can run on personal computers, as well as large systems. Beckman's systems provide extensive data analysis for general chromotography, simulated distillation, gel permeation, continuous flow and potentiometric titration. For sample, test and method and result management, the database is determined by the laboratory and updated on-line. The systems provide a configurable operational sequence and configurable sample and test status requirements according to the laboratory's specifications. The systems feature long-term archiving and recall. Beckman systems can communicate with other CALS systems, personal computers and mainframe computers.

Biotechnology manpower in the UK

from Richard Pearson

The best brains will not remain in this country unless the best jobs are here too.

BIOTECHNOLOGY is one of the fast growing new technologies. It was born as late as the 1970s and is recognized everywhere as a key technology for the future. As well as the United States and Japan, the technology superpowers, France, West Germany, Switzerland and the United Kingdom have taken initiatives to develop their biotechnology, even though the industry has barely moved out of the fundamental research stage. Being a knowledge-based industry, the availability of skilled manpower is crucial to its future success. In the United States, the Office of Technology Assessment has assessed prospects for that country and also provided an international overview, and has highlighted the strengths and weaknesses of different countries' manpower (see *Nature* **307**, 399; 1984). In the United Kingdom, the Science and Engineering Research Council (SERC) has been trying to ensure adequately trained manpower to support this emerging technology and has just published two reports prepared for it by the Institute of Manpower Studies (*Enabling Manpower for Biotechnology* and *The Biotechnology Brain Drain*).

There are now almost 2,000 professional specialist personnel active in novel biotechnology in the United Kingdom in addition to those engaged in traditional areas such as brewing. While a precise definition of a "biotechnologist" is inappropriate, most individuals being regarded as, say, microbiologists, biochemists or biochemical engineers, it is clear that, on the science side at least, few people would be regarded as professional biotechnologists without three or more years postgraduate experience; on the process engineering side, however, the entry threshold is more likely to be a first rather than a higher degree.

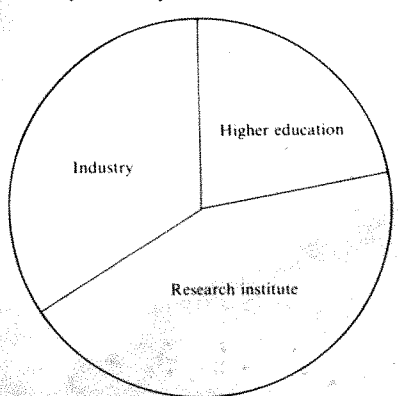

Fig.1 Distribution of biotechnologists in UK institutions.

The 2,000 specialists in the United Kingdom are employed in more than 100 organizations, some with just one or two, others with more than 50. One research laboratory employed over 100. The type of organization involved did not, however, indicate the actual employment level — two major pharmaceutical companies, for example, each employed fewer than 25 specialist biotechnologists, much of their basic research being contracted out to university-based research groups.

The commercial sector accounted for nearly half the employment at professional level, with research institutions taking about a third and the balance in higher education, although in the latter it was sometimes difficult to isolate applied biotechnologists from those focusing on more fundamental aspects of science (Fig.1). With the rapid growth of commercial companies spinning off from academic departments, consultancies and so on, the dividing line between the sectors is also becoming increasingly blurred.

With the exception of junior staff and chemical engineers, who were often recruited either after a first or possibly master's degree, most recruits to biotechnology had had some relevant postgraduate research experience and were typically in their mid to late 20s or early 30s. Apart from new companies or centres starting up, the numbers recruited rarely exceeded ten vacancies in a year in any one company. Wastage rates were also generally low. The only significant shortage of suitably experienced personnel was in fermentation technology, particularly microbial physiologists, biochemical engineers and bioscientists with research and development experience of plant and tissue cell culture. There was also a shortage, as in many other technologies, of people who could combine technical and managerial expertise.

One particular concern of the past few years has been the potential scale of the brain drain (see *Nature* **308**, 572; 1984). The study estimated that about 250 UK nationals had gone abroad since the mid-1970s, representing perhaps 13 per cent of the number currently employed in the United Kingdom. The peak flow was about 30 per annum in 1981 and 1982. UK nationals were found working in 13 countries; the main destinations were the United States (46 per cent), followed by Switzerland (16 per cent) and then Canada,

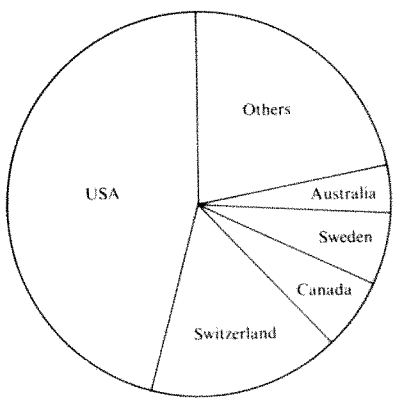

Fig.2 UK biotechnologists taking positions overseas.

Sweden and Australia (Fig.2). The largest loss was from higher education institutions and the main flow was to commercial organizations. More than 65 different overseas organizations were known to have recruited UK nationals. One recruited at least 16 UK nationals, four others took four or more each. One in three of those who had gone overseas had changed jobs since leaving the United Kingdom, and one in eight had also changed countries.

Typically the leavers were aged 26 to 30, although one in three was over 30. Nearly one in three went to "senior" jobs overseas, at professorial or departmental head level. They reported that the main reason for leaving was not salary but the lack of "suitable" opportunities and jobs in the United Kingdom. Most of them did not expect to return to the United Kingdom because they would be unwilling to take a reduced salary and standard of living. Thus while salary is not a motivation in leaving, it is a barrier to returning. While the flow overseas included a number of people who had left senior appointments in the United Kingdom and were unlikely to return, some were young postdocs moving overseas for experience, part of the normal international interchange of scientific personnel. While the outflow had no significant impact on individual organizations, such losses being only one part of their wastage to other employers, the flow was regarded as a lost opportunity and weakening of the United Kingdom's scientific base. The future flows, in either direction, will depend on job opportunities in the United Kingdom and salary differentials. □

Richard Pearson is at the Institute of Manpower Studies, Mantell Building, University of Sussex, Brighton BN1 9RF, UK.

UNIVERSITY OF BIRMINGHAM

Faculty of Medicine and Dentistry

DEPARTMENT OF IMMUNOLOGY

Applications are invited for the post of Research Fellow 1A funded by Arthritis and Rheumatism Council for up to two years from 1 September 1984. Project will study the molecular specificity and clonality of rheumatoid factors and involve the production of monoclonal antibodies to human IgG epitopes and rheumatoid factor idiotopes.

Salary on scale £7,190 — £11,615 with superannuation maximum starting salary £8,975.

Further information Dr J Jefferis, Department of Immunology. Applications (three copies to Assistant Registrar, Medical School, Birmingham B15 2TJ by 28 June 1984) quote ref RF/IMM/NGA. (2881)A

THE UNIVERSITY OF MANCHESTER

TEMPORARY LECTURER IN PHYSICS

Applications are invited for the above post tenable from October 1st, 1984 for a period of one year. Applicants should have an interest in one of the current research areas of the Department, namely Astronomy, Radio/Astronomy, Low temperature and Condensed Matter Physics, Atomic, Molecular and Polymer Physics including Liquid Crystals, Optics, Nuclear Structure Physics, Particle Physics and Theoretical Physics.

Salary range £7,190 — £8,530 pa (Superannuation).

Applications with names of three referees should be sent to the Registrar, The University, Manchester M13 9PL by June 29th. Quote ref 140/84/N. (2372)A

UNIVERSITY OF GUELPH

COLLEGE OF BIOLOGICAL SCIENCE

PRE AND POST DOCTORAL POSITIONS

Available for training in the Molecular Biology of post transcriptional control with special emphasis on structure and function of mRNP complexes and bio-genesis of ribosome particles in procaryotic and eucaryotic systems. Studies of this laboratory are directed to examining molecular events which occur during changes in growth rate and differentiation. Teaching opportunities available. Stipends for post doctoral fellows are $17,500 to $21,000 and according to departmental guidelines for pre doctoral fellows.

Please send résumé and names of three referees to: Bruce H Sells, College of Biological Science, University of Guelph, Guelph, Ontario, Canada N1G 2W1. (NW598)A

INSTITUTE OF CHILD HEALTH
UNIVERSITY OF LONDON

RESEARCH PSYCHOLOGIST

Psychologist/Human Biologist required for one year in the first instance, but with possibility of renewal, to undertake a feasibility study on the adverse physical and psychological effects of the intensive training of young athletes. The study is funded by the Sports Council and directed by Professor Philip Graham and Dr Peter Helms. The feasibility exercise may be followed by a major study. The successful applicant will have some previous research experience. Starting salary within the range £10,710 to £13,515 per annum plus London Weighting, according to qualifications and expericence.

Further details and application forms from the Assistant Secretary (N258804), Institute of Child Health, 30 Guildford Street, London WC1N 1EH, to whom completed application forms should be returned by 6 July 1984. (2304)A

Entomologist

Creative career opportunity for a Young Research Professional

We are one of the world's largest chemical companies and a major supplier of agricultural chemicals to U.K., Europe and the Middle East. Our research and development centre at King's Lynn has an international reputation for excellence and with our continued expansion we now wish to add a high calibre research Entomologist to our multi-disciplined team.

Ours is an intensely creative environment — originating and developing new products in pesticide science to the highest standards.

We would expect you to be in your twenties with at least a good honours degree in a biological discipline and a knowledge of agricultural entomology. You will need to be experienced in laboratory, glasshouse and small plot field trials and be able to carry out these with minimum supervision. You must have the research ability to progress ideas to a successful conclusion.

It has always been the policy of Dow as an international organisation to encourage responsibility at an early stage in your career with the Company. For someone who has the enthusiasm, flexibility and the creative input needed for successful research, the initial salary and benefits are excellent and future career prospects on an international scale, impressive.

To find out more please write or telephone for an application form to: Liz Sim, Personnel Officer, Dow Chemical Company Limited, Crossbank Road, King's Lynn, Norfolk PE30 2JD. Telephone: King's Lynn (0553) 61251.

AUSTRALIAN INSTITUTE OF MARINE SCIENCE

DIRECTOR

The Australian Institute of Marine Science is a Statutory Body established by Act of Parliament in 1972. The main functions of the Institute are:

- to carry out research in marine science;
- to arrange for the carrying out of research in marine science by any other institution or person;
- to co-operate with the other institutions and persons in carrying out research in marine science;
- to provide any other institution or person with facilities for carrying out research in marine science or otherwise assist any other institution or person in carrying out research in marine science;
- to collect and disseminate information relating to marine science, and in particular to publish reports, periodicals and other papers relating to marine science.

Under the general direction of a Council, the Institute is managed by a Director who holds office for a period not exceeding seven years, although he or she is eligible for re-appointment. The present Director will complete his seventh year in office on August 22, 1985, and expressions of interest in appointment to that position are now sought.

The Institute's headquarters are in a modern and well-equipped laboratory complex in pristine waterfront surroundings 55 km by road from the city of Townsville in North Queensland. The complex itself occupies a floor area of 10,000m² on several levels and incorporates a major library, computer facility, electronic and mechanical workshops and extensive laboratory space with comprehensive scientific instrumentation. In its position facing the Coral Sea, the Institute also has docking for its research vessels which include the 24.4 m R/V Lady Basten, the 13.66 m R/V Sirius, the 21 m R/V Harry Messel, on long term charter, and a number of smaller craft. A fully-equipped dive locker and recompression chamber service the needs of research underwater.

The present staff is 104 full time and 10 part time appointees including 20 research scientists. There are at present five multi-disciplinary programs addressed to coastal wetlands, nearshore physical processes and productivity, coral reef metabolism, coral reef ecology and the physical, chemical and biological processes associated with the shelf and adjacent seas, particularly but not entirely of the Great Barrier Reef. The major thrust of current research is in the environment of the Australian marine tropics.

Considerable emphasis is placed on interaction and collaboration with individuals and research organizations with complementary interests, both within Australia and overseas. The Institute has close and formal affiliations in research with James Cook University in Townsville. For interaction with collaborators further afield, the Institute maintains six fully self-contained cottages and six bachelor apartments, all on site. The accommodations also enable the Institute to host frequent workshops and symposia.

The Institute is fully committed to research. Although its functions do not include teaching, it regularly provides facilities for research by graduate students and it operates its own post-doctoral award scheme to augment in-house research activities.

Qualifications

The office of the Director is one of considerable seniority and responsibility. The successful appointee must have well-recognized academic qualifications and a demonstrable, and firmly established and active international reputation in some field or fields of marine science. Candidates must also have a broad grasp of marine research, and understanding of and enthusiasm for multidisciplinary activity and a depth of understanding and experience in research management in all its aspects including interaction with the agencies of Government. Enquiries in the first instance may be made by writing in confidence to the address given below. Formal applications should include documentation of professional experience and achievement (c.v.) and the names of not more than 5 referees. Applications must be dispatched no later than **September 1, 1984.**

Dr John L. Farrands, CB, FTS
Chairman
Australian Institute of Marine Science

NIHE

NATIONAL INSTITUTE FOR HIGHER EDUCATION DUBLIN

Applications are invited for a:-

LECTURESHIP IN CHEMICAL SCIENCES

The School of Chemical Sciences is centrally involved in the BSc degree course in Analytical Science, in addition to servicing other courses, and possesses a comprehensive range of modern analytical instrumentation. The appointed candidate will become involved in the implementation and further development of teaching programmes and will be expected to initiate and develop programmes of research and to become involved in expanding links with industry.

Applicants should have interests in one or more of the following areas:

Analytical Science (instrumental aspects, inorganic analysis, separations science),

Applied Chemistry (areas of applied inorganic, organic or physical chemistry).

Applicants should be well-qualified academically with appropriate research, teaching or industrial experience.

Salary Scale: Lecturer IR£13,797 - IR£18,807
Assistant Lecturer IR£10,727 - IR£13,218

Application forms, and further details, are available from the Personnel Office, National Institute for Higher Education, Glasnevin, Dublin 9, Ireland. Closing date: 3 August 1984.

(2875)

OXFORD POLYTECHNIC
Chipsy Lane, Headington, Oxford OX3 0BP

DEPARTMENT OF BIOLOGY

Postgraduate Research Training

Three opportunities for research training, leading to MPhil/PhD (CNAA), will exist in the department from 1 September 1984. The following project areas are available:

Photoperiodism and Reproduction; Feedback control mechanisms on ion absorption and transport in higher plants; Allosteric models and haemoglobin; Production and characterisation of monoclonal antibodies for use in a diagnostic kit to detect demyelination; Biochemical mechanisms of resistance to aminoglycosides in clinically isolated bacteria; Laboratory selection for pesticide resistance in predatory mites; Glycoprotein metabolism in nerve terminals; *In vitro* construction of Tn5-derived transposons carrying novel selective markers and transactivated oriT regions; Physiological and biochemical indicators of alcohol consumption in support of clinical therapies; Numerical aspects of species diversity in insects.

Further details of the projects and of research in the Department available from the Postgraduate Tutor. Two of the posts are Researcher A appointments (£4,947 pa under review) associated with some teaching duties in physiology and biochemistry respectively.

Applicants should possess a good honours degree in an appropriate subject. They should provide a curriculum vitae including full details of any experience relevant to the project they nominate, and the names of two academic referees. Applications should be sent as soon as possible to:

Oxford Polytechnic, Chipsy Lane, Headington, Oxford OX3 0BP. Tel 0865 64777.

DEPARTMENT OF GEOLOGY AND PHYSICAL SCIENCES

Temporary Lecturer II/ Senior Lecturer in Geology

Ref. GPS/ 31

Applications are invited for a one-year, full time temporary post in the Department from suitably qualified candidates. The post will be available from 1 September 1984 to 31 August 1985.

The successful candidate will in part, be responsible for the teaching of Petrology and Mineralogy as part of the Polytechnic's modular degree course. Petrology and Mineralogy are taught within the named degree in Earth Sciences and the Geology single field honours degree.

Teaching responsibilities will be in at least two of the following areas; Metamorphic Petrology; Igneous Petrology with special reference to Plutonic Rocks; Introductory Mineralogy and Petrology. In addition the successful candidate will be required to supervise undergraduate field trips, may be required to teach geological map work and will be encouraged to participate in research.

Salary Scale LII £7,215 — £11,568
Salary Scale SL £10,683 — £13,443 (under review)

Further details and application forms are available from the Staffing Department, ext 364, Oxford Polytechnic, Chipsy Lane, Headington, Oxford OX3 0BP. Tel: 0865 64777.

The closing date for these posts is 22 June 1984.

(2890)A

UNIVERSITY OF LONDON INSTITUTE OF PSYCHIATRY

DEPARTMENT OF PSYCHOLOGY

Applications are invited for a

LECTURESHIP

The successful candidate will be required to provide a service to the Neurosurgical Unit and to the Epilepsy Ward of the Bethlem Royal and Maudsley Hospital. Applicants will also be expected to participate in the teaching of the Department on the MPhil Clinical Psychology Course and in the supervision of trainees. They must be capable of taking an initiative in developing the clinical and research services of psychologists in this new unit. Applicants should possess appropriate postgraduate qualification in clinical psychology and relevant experience is desirable.

Salary in accordance with the University of London Lecturer Scale £7,190 — £14,125 plus London Weighting allowance.

Application forms and fuller job description obtainable from Anne Stevens, Department of Psychology, De Crespigny Park, London SE5 8AF, and should be returned by Friday, 29th June 1984. (Tel: 703-5411 ext 321). (2303)A

Immuno-Diagnostics R&D

Our clients are the UK subsidiary of an innovative, and highly successful, international health care organisation. As part of its commitment to continued advancement, the UK diagnostics division is now undergoing a major expansion and seeks several experienced scientists within its R & D group.

The appointments will be based in new purpose-built premises in a pleasant part of the Southern Home Counties. They command an attractive remuneration package, including generous relocation expenses if required.

Immunoassay Specialists

2 PROJECT LEADERS, each taking responsibility for developing enzyme immunoassay techniques for a number of novel diagnostic kits.

Applicants should ideally hold a PhD and have several years' post-doctoral experience in immunoassay techniques, in conjunction with the use of enzymes. In addition they should have good written and verbal communication skills with the ability to direct and motivate staff.

5 PROJECT SCIENTISTS, each becoming a member of an enzyme immunoassay development team working with monoclonal antibodies.

Candidates should have at least a BSc in a relevant science and experience of immunoassay techniques, ideally also using enzymes.

Protein Chemist

To undertake the development of new enzyme monoclonal antibody reagents, and provide technical expertise and guidance for the improvement of existing products.

The ideal candidate would be a PhD protein chemist, with at least two years' relevant postdoctoral research experience, including the preparation of enzyme conjugates for immunodiagnostics.

Cell Culture Scientist

The main task will be to use tissue culture techniques to establish and maintain the production of monoclonal antibodies from hybridoma cells.

The successful candidate is likely to hold a PhD and have several years' post doctoral experience with project responsibility for tissue culture techniques.

Please write in confidence for an application form, or phone if you would like to discuss the appointments further:

SQUIBB

R&D DIRECTOR
Japan

Squibb, a major international pharmaceutical company, currently is seeking candidates for the position of R&D Director in its Japanese affiliate with offices in Tokyo. The Director must provide strong intellectual and administrative leadership to a staff of about 50 scientists who have responsibility for the registration in Japan of new human ethical and animal health products. In meeting these responsibilities, the department monitors Japanese regulatory requirements, oversees preclinical and clinical studies conducted in Japan, and prepare the necessary registration documents. Throughout this process, close liaison is maintained with the central research laboratories in the United States.

The successful candidate will have at least 15 years experience in the health care field after receiving an MD or PhD degree (or equivalent) and must be fluent in both Japanese and English.

Interested candidates should send their current resume directly to: **Mrs. Anne V. Corey, International Personnel Director, Squibb Corporation, P.O. Box 4000, Princeton, NJ 08540.** An equal opportunity employer.

(NW577)A

BATTELLE-KETTERING SENIOR POSITIONS

Battelle-C.F. Kettering Research Laboratory, located in Yellow Springs, Ohio, has two research positions available. The laboratory's research programs are oriented toward increasing agriculture productivity through research in the general areas of symbiosis, nitrogen fixation and photosynthesis.

One position requires a PhD in molecular genetics with related experience in appropriate bacterial and/or plant sciences. A PhD in plant sciences and five years experience is required for the second position which will serve to complement our current expertise and ongoing research activities. The successful applicants will be expected to support their research efforts by obtaining externally funded grants and contracts.

Battelle offers a competitive salary, excellent employee benefits, and career growth opportunities. Applicants with appropriate interests and expertise should send their résumé to Richard Shaw, Employment Department U-2.

Battelle

Memorial Institute
505 King Avenue • Columbus, OH 43201
An Equal Opportunity/Affirmative Action Employer

(NW593)A

THE AUSTRALIAN NATIONAL UNIVERSITY
JOHN CURTIN SCHOOL OF MEDICINE RESEARCH
Postdoctoral Fellow/ Research Fellow/ Senior Research Fellow (several positions)

Applicants for these research positions should have a PhD degree (or equivalent qualification) and expertise in any of the areas of research listed below. A number of appointments will be available from early 1985.

DEPARTMENT OF BIOCHEMISTRY: (Head: Professor F. Gibson)
Energy-transducing ATPase; membrane assembly; bioenergetics; mechanism of action of classical and multifunctional enzymes; molecular biology; gene expression; differentiation; oncogenesis.

DEPARTMENT OF EXPERIMENTAL PATHOLOGY: (Head: Professor P.C. Doherty)
Biology and biochemistry of tumour metastasis, malignancy and host response; viral and auto-immune pathological process in the central nervous system; vascular and lymphatic pathology; inflammation; pathogenesis of malaria.

DEPARTMENT OF HUMAN BIOLOGY: (Head: Dr R.L. Kirk)
Molecular biology of inherited disease, cytogenetics and somatic cell genetics; human population genetics, including DNA polymorphisms.

DEPARTMENT OF IMMUNOLOGY: (Head: Professor B. Morris)
Ontogeny of the immune response; immunology of the foetus and pregnancy; experimental surgery of the embryo and feotus; embryo transplantation; genetics of disease resistance; reproductive and developmental biology; tissue transplantation; physiology of the lymphatic system.

DEPARTMENT OF MEDICINE AND CLINICAL SCIENCE: (Head: Professor W.F. Doe)
Mucosal immunity and inflammation; neutral proteases; interleukins and differentiation of bone marrow cells, macrophages and natural killer cells; pathogenesis of inflammatory bowel disease and colon cancer; neurophysiology of intestinal motility; calcium and cell regulation; malignant hyperpyrexia; asthma; platelets, atheroma and haemostasis; transplantation biology.

DEPARTMENT OF MICROBIOLOGY: (Head: Professor G.L. Ada)
Properties of infectious agents, especially viruses; epidemilogical studies of, and immune responses, particularly cell-mediated responses, to viral infections; transformation of cells by viruses; engineering of viruses to make better vaccines; surveillance mechanisms against tumours; membrane structures and antigens, such as histocompatibility antigens, involved in cell-cell recognition.

DEPARTMENT OF PHARMACOLOGY: (Head: Professor D.R. Curtis)
Mammalian central transmitters; pain and analgesia; mammalian peripheral sympathetic synapses; biophysics of smooth muscle; nerve growth factors.

DEPARTMENT OF PHYSICAL BIOCHEMISTRY: (Head: Professor L.W. Nichol)
Biological macromolecules; interacting protein systems; multienzyme complexes; enzymes of sulphur metabolism; protein conformation and hydration; secretory and blood proteins.

DEPARTMENT OF PHYSIOLOGY: (Head: Professor P.W. Gage)
Synaptic transmission at peripheral and central synapses; effects of general anaesthetics; calcium ionic and gating currents; charge movements in nerve and muscle; contractile activation in muscle; visual information processing.

EXPERIMENTAL NEUROLOGY UNIT: (Director: Professor R. Porter)
Neurophysiology; spinal cord; synaptic transmission at central synapses; respiratory neurophysiology; somatosensory pathways; control of movement; physiology of the cerebral cortex in primates.

INFLUENZA VIRUS IMMUNOCHEMISTRY LABORATORY: (Dr W.G. Laver)
Structure and variation of influenza virus antigens and their antibodies.

CONDITIONS OF EMPLOYMENT: Salary will be in accordance with qualifications and experience within the range: Senior Research Fellow: $A35720 — $42607 p.a.; Research Fellow: $A25571 — $33594 p.a.; Postdoctoral Fellow Grade 1 (at fixed point on scale) $A22041 — $25249 p.a. ($A1 = £0.64p approx.).

Appointment as senior Research Fellow/Research Fellow will be for up to three years initially with the possibility of extension after review to maximum of five years; as Postdoctoral Fellow for one or two years initially with possibility of extension to maximum of three years.

Grants are provided towards travel and removal. Assistance towards housing is given to an appointee from outside Canberra. Eligible appointees will be required to join the Superannuation Scheme for Australian Universities. The University reserves the right not to make an appointment or to make an appointment by invitation at any time. Maternity leave is available.

Prospective applicants are encouraged to write to the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or to the Acting Registrar Australian National University, GPO Box 4, Canberra, ACT2601, Australia, for further information before lodging applications with the Acting Registrar of the University. Closing date for receipt of applications is *17 August 1984.*

The University is an equal opportunity employer. (W1052)A

Agricultural and Food Research Council

SECRETARY TO THE COUNCIL

The present Secretary, Dr Ralph Riley, FRS, is retiring in mid-1985 and a successor is being sought.

The primary aims of the Council are to advance scientific knowledge relevant to agriculture, horticulture and food supply; to exploit this knowledge to increase the efficiency of the industries concerned; and to safeguard and improve the quality of food.

The Secretary is the Chief Executive of the Council. The main responsibilities of this position are:

☐ The overall management and scientific leadership of the Agricultural and Food Research Service which has an annual budget of about £100m and some 4250 staff. About half of the budget is provided by the Department of Education and Science from the Science Budget.

☐ Chief representative of the Council in its capacity as contractor to the Ministry of Agriculture, Fisheries and Food for commissioned research which accounts for the other half of the budget.

☐ All secretariat functions of the Council.

☐ Accounting Officer for the Council's grant-in-aid.

☐ A Member of the Advisory Board for the Research Councils.

Applications are sought from individuals with a distinguished background in a science or technology relevant to agriculture and/or food, who can also demonstrate that they possess the necessary management skills and judgment for this appointment.

It is likely that eligible candidates are today holding senior positions in research, either within industry or academia.

The age of the successful candidate must allow for at least five years in the post.

The present salary of the post is £35,125 p.a. A contribution towards relocation expenses may be made.

Those interested should write in confidence enclosing a brief curriculum vitae to the Management Consultants who are advising the Council on this recruitment, as follows:

The Chairman
Spencer Stuart Management Consultants
Brook House, 113 Park Lane
London W1Y 4HJ

(2305)A

THE MEDICAL COLLEGE OF ST. BARTHOLOMEW'S HOSPITAL

(University of London)
West Smithfield, London EC1A 7BE.

'NEW BLOOD' LECTURESHIP IN EPIDEMIOLOGY AND MEDICAL STATISTICS

Applications are invited from non-medically or medically qualified scientists experienced in biostatistics and epidemiology for the above 'New Blood' Lectureship tenable within the Department of Environmental and Preventive Medicine. This department is currently conducting case-control and prospective studies into the aetiology of disease and multi-centre clinical trials of disease prevention. The Lecturer would work as a member of an epidemiological research group and be expected to play an important role in the initiation of new research projects.

The appointment will be available from September/October 1984 and will be for a period of three years initially, with the possibility of renewal or subsequent transfer to a continuing appointment. Candidates should normally be aged under 35, and persons holding permanent university appointments in the UK are not eligible. The salary will be at an appropriate point on the relevant University Lecturer Scale.

Any applicants who would like to discuss the post are invited to contact Prof. N. Wald, Dept. of Environmental & Preventive Medicine at the Medical College, Charterhouse Square, London EC1M 6BQ (tel 01-253 0661 ext 148).

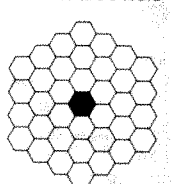
Applications in the form of a curriculum vitae (six copies please) should be sent to the Dean of the Medical College, West Smithfield, London EC1A 7BE (quoting ref. JR.14), together with the names of three referees, not later than 16th July 1984.

(2306)A

PROJECT MANAGER

TEN METER TELESCOPE

University of California



Applications are invited for the current opening of Project Manager (PM) for the University of California Ten Meter Telescope (UC TMT). The PM will have overall project responsibility for planning, engineering design, cost estimation, scheduling, and budget management for procurement, fabrication, and construction during the design and construction phases of the TMT and related facilities. In the determination of design and performance specifications, and the development of engineering design concepts, the PM will work in close cooperation with the Project Scientist.

Applicants should have demonstrated ability to complete major projects on time and within budget. Experience in the development of stand-alone research facilities is valuable. Knowledge of electro-mechanical and optical systems, computer environments, structural engineering, and laboratory research facility designs is desirable. Experience as manager of major research construction projects is a requirement. Applicants with degrees in engineering or physical sciences are preferred.

The PM will be an Associate Director of Lick Observatory reporting to a UC Executive Management Committee (EMC). Salary will be commensurate with experience and qualifications.

Applicants should send resume and the names of three persons who have been asked by the applicant to submit letters of professional reference directly to the Chair. All application materials should be received by September 15, 1984 and sent to:

Dr. Harold Ticho
TMT/EMC Chair
c/o Lick Observatory
University of California
Santa Cruz, California 95064

An EEO/AA Employer

(NW600)A

KING SAUD UNIVERSITY COLLEGE OF AGRICULTURE & VETERINARY MEDICINE QASSEEM, SAUDI ARABIA

Applications are invited on one year renewable contracts as:

1. ASSISTANT PROFESSOR (RESEARCH) — PHARMACOLOGY

Applicants must be Ph.D holders with experience in isolation, characterization and studies on therapeutic effects of isolated compound of plant origin.

2. ASSISTANT PROFESSOR RESEARCH — PHARMACOGNOSY

Applicants must be Ph.D holders with experience in isolation and characterization of medicinal principles in plants.

Applicants are expected to develop strong research programmes in the field of Medicinal Plants and Isolate Principles, and to characterize and study the mode of action in experimental animals.

3. TECHNICIANS IN PHARMACOLOGY AND PHARMACOGNOSY

Applicants must hold FIMLS or equivalent qualification and have substantial experience in advanced methods of chemical analyses with modern laboratory equipment, and experience in plant material extractions, chromatographies and methods of bioassoy.

Benefits include:

* competitive tax free salaries
* free furnished accommodation or housing allowance
* free yearly return air tickets for incumbent and family
* monthly transport allowance
* free medical/dental care
* children's educational allowance
* end of service gratuity

Applications should be sent, together with a photograph and non-returnable photocopies of academic credentials, to: Ms Carmel Donnachie, King Saud University Office, 29 Belgrave Square, London SW1.

Interviews will be held in London during the second week of July (approx.). (W1049)A

POSTDOCTORAL FELLOW

Postdoctoral Fellow interested in research in Cell Adhesion. Position for 2-3 years; starting salary: 18K.

Send CV and two letters of recommendation to: Fred Grinnell, Department of Cell Biology, The University of Texas Health Sci Ctr, Dallas, Texas 75235.

An Affirmative Action/Equal Opportunity Institution. (NW595)A

POSTDOCTORAL Position available to study the mechanism of coupling of muscarinic cholinergic receptors to the adenylate cyclase and phosphoinositide systems of the molecular basis of agonist induced desensitization of muscarinic cholinergic receptors in cultured cells. Send vita and three letters of reference to Dr T K Harden, Dept Pharmacol Univ North Carolina at Chapel Hill, School of Medicine, Chapel Hill, NC 27514. (NW596)A

UNIVERSITY OF EDINBURGH
DEPARTMENT OF CHEMISTRY

POSTDOCTORAL RESEARCH IN ORGANIC CHEMISTRY

Applications are invited for a Postdoctoral appointment to take part in a joint research programme investigating the synthesis of carbohydrates and analogues using cycloaddition reactions. The work will be carried out in association with Dr. R.M. Paton (University of Edinburgh), from whom further details may be obtained, and Dr. R.A.C. Rennie (Corporate Bioscience Group, ICI plc). The post is tenable for 3 years and is funded by the SERC Cooperative Awards Scheme. The salary will be on the RA/1A scale starting at £7630.

Previous experience in carbohydrate chemistry would be advantageous but is not essential.

Applications, giving curriculum vitae and the names of two referees, should be sent as soon as possible to Dr. R.M. Paton, Department of Chemistry, University of Edinburgh, West Mains Road, Edinburgh. EH9 3JJ.

Please quote reference no. 5176. (2337)A

UNIVERSITY OF SYDNEY

DEPARTMENT OF VETERINARY PHYSIOLOGY

(REFERENCE NO 22/01)

LECTURESHIP

Appointee will have research and teaching experience in mammalian physiology and an interest in contributing to development of self-instruction and audio visual programmes in courses of physiology offered in the Department to students of veterinary science and agricultural science. The major research interests in the Departments are physiology of the digestive and reproductive systems.

Salary range: $A24,353 — $31,994 pa (under review).

Appointments to lectureships are usually probationary for three years and the University reserves the right not to proceed with any appointment for financial or other reasons.

Applications, quoting reference no, including curriculum vitae, list of publications, the names of three referees to the Registrar, University of Sydney, NSW 2006, Australia, by 13 July 1984. Further general information available from Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (W1061)A

THE FLINDERS UNIVERSITY OF SOUTH AUSTRALIA

PROFESSOR OF CHEMISTRY
(Organic Chemistry)

Applications are invited from chemists working in any area of organic chemistry for appointment to a second Chair of Chemistry in the School of Physical Sciences. The Professors are expected to provide leadership both in research and in the teaching of chemistry in the University.

Currently, the major areas of research in organic chemistry are the synthesis of alicyclic compounds for NMR and substituent effect studies; organometallic chemistry, and the synthesis of aromatic compounds of medical interest. Other major areas of research in chemistry are the structure and reactivity of solids and solid surfaces, catalysis and electrochemistry.

Salary: $A51,006 a year (academic salaries are currently under review).

Enquiries of an academic nature may be directed to Professor B.G. Baker, School of Physical Sciences. Further information about the position, the conditions of appointment (including superannuation arrangements) and details required of applicants may be obtained from the Secretary General, The Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications should be lodged, in duplicate, with the Registrar, The Flinders University of South Australia, Bedford Park, South Australia 5042, by 17 August 1984. (W1058)A

UNIVERSITY OF WARWICK
POSTDOCTORAL RESEARCH FELLOW IN MICROBIOLOGY

In the Department of Biological Sciences to work on a project funded by the SERC. The work will be concerned with the modifications to mRNA Biochemistry in Cyanobacteria and their physiological implication. Salary will be on the Research 1A scale: £7,190 to £11,615 pa. The position is available from 1st July 1984 for two years three months.

Applicants should send a cv detailing relevant experience, together with the names and addresses of two referees, to the Executive Officer, Department of Biological Sciences, University of Warwick, Coventry CV4 7AL, quoting reference NGC/NAR, by 29th June, 1984.

Informal enquiries can be made direct to Dr N G Carr, Biochemistry Department, University of Liverpool, 051-709 6022 ext 2518. (2310)A

THE AUSTRALIAN NATIONAL UNIVERSITY
Research School of Biological Sciences

DEPARTMENT OF NEUROBIOLOGY

RESEARCH FELLOW/SENIOR RESEARCH FELLOW

Applicants should have experience in the analysis of insect central neural processing. Skill with microelectrode recording, dye filling, and the use of computers for data processing would be an advantage.

Salary will be in accordance with qualifications and experience within the ranges: Senior Research Fellow $A35,720 — $A42,607 pa; Research Fellow $A25,571 — $A33,594 pa ($A1: £0.64p: $US0.89 approx).

Appointment will be: Senior Research Fellow/Research Fellow normally up to three years with the possibility fo extension to maximum of five years.

Grants are provided towards travel and removal. Assistance toward housing is given to an appointee from outside Canberra. Eligible appointees will be required to join the Superannuation Scheme for Australian Universities. Maternity leave is available. The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should write to the Acting Registrar Australian National University GPO Box 4, Canberra, ACT 2601 Australia, or to the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, for further particulars before submitting applications which close with the Acting Registrar of the University on 25 July 1984.

The University is an equal opportunity employer. (W1045)A

ADJUNCT ASSISTANT PROFESSOR

Position available January 1, 1985 for a molecular biologist with a primary interest in hormone action and gene expression. The applicant must have a PhD or equivalent, plus postdoctoral experience in techniques of molecular biology, including general recombinant DNA techniques, methods of chromatin structure studies and gene transfer. Applicants must be willing to work collaboratively with other molecular biologists in a research institute setting.

Send applications to Dr John Baxter, Chairman, Search Committee, Metabolic Research Unit, 671-HSE, University of California, San Francisco, CA94143. The University of California San Francisco is an Equal Opportunity/Affirmative Action employer. Women and minorities are encouraged to apply. (NW604)A

THE UNIVERSITY OF WESTERN AUSTRALIA
Perth

SENIOR TUTORSHIP IN GEOLOGY (PALAEONTOLOGY) (FIXED TERM)

Applications are invited from candidates with a higher degree and research experience in the field of palaeontology for a three year fixed term Senior Tutorship to commence in August 1984. All interested and qualified persons are encouraged to apply, but the department will particularly welcome enquiries from candidates with a background in the applications of palaeontology to sedimentology and stratigraphy. Some knowledge of micropalaeontology would also be an advantage.

The appointee will be asked to assist in the design and teaching of undergraduate courses in palaeontology and stratigraphy, including field training in sedimentary terrains. Supervision of honours students will also be required and the successful applicant will be encouraged to develop research programmes, either as an individual or in collaboration with others. Western Australian sedimentary basins comprise extensive areas and thicknesses of sedimentary rocks and almost all geological systems contain abundant fossil fauna. The Devonian, Permian, Jurassic, Cretaceous and Quaternary in particular provide material for significant research.

Current salary range: $A20991 - $A24047 per annum. Benefits include superannuation, fares to Perth for appointee and dependent family and removal allowance. Conditions of appointment will be specified in any offer of appointment which may be made as a result of this advertisement.

Applications in duplicate stating full personal particulars, qualifications and experience and the names and addresses of three referees, should reach the Staffing Officer, University of Western Australia, Nedlands 6009, Western Australia, by 28th July 1984. (W1057)A

UNIVERSITY OF NOTTINGHAM
MEDICAL SCHOOL
DEPARTMENT OF PATHOLOGY

WELLCOME TRUST LECTURESHIP

Applications are invited for the position of Lecturer (Medical or Non-Medical) in the Department of Pathology at Queen's Medical Centre, Nottingham. The purpose of this Lectureship is to enable a young medical or non-medical graduate to engage in a major research programme in some aspect of tissue pathology or related basic science subject. The Wellcome Trustees have made this award for three years in the first instance with the possibility of renewal for a further two years.

Applications should be supported by a 500 word summary outlining a proposed research programme. Prospective applicants should be less than 35 years of age and should not already hold a tenured post. Salary will be on the Lecturer scale with membership of USS.

Further information and application forms may be obtained from the Deputy Registrar, Medical School, Queen's Medical Centre, Nottingham NG7 2UH. (Telephone (0602) 700111 extension 3202), to whom completed applications should be returned by 10th July 1984. (2324)A

THE OPEN UNIVERSITY
Faculty of Science

TEMPORARY LECTURESHIP IN PHYSICS

Applications are invited for a temporary post as Lecturer in Physics at The Open University. The successful applicant will join a team of others to prepare course material for a second level physics course in Properties of Matters, using multimedia teaching techniques. In addition, the successful candidate is expected to carry out research. The Physics Discipline has individuals or groups active in the following areas: Atomic and Molecular Spectroscopy, Biomagnetism, Nuclear Structure Physics, Theoretical High Energy Physics, Solar Energy and Semi-Classical Approaches to Quantum Mechanics, and applications from candidates active in any of these fields would be especially welcome.

This post is available for three years from 1st September 1984. The salary will be at a point on the Lecturer A4 salary scale £7,190 — £14,125 pa depending on age and experience.

Candidates should hold a first degree and a PhD in Physics. An interest in distance teaching will be an advantage.

Application form and further particulars are available from The Assistant Secretary (Science) (4748/2), The Open University, Walton Hall, Milton Keynes MK7 6AA or telephone Milton Keynes (0908) 653481/653993: there is a 24 hour answering service on 653868.

Closing date for applications: 2nd July. (2368)A

AUSTRALIA

Chemical/Mechanical Engineer or Physicist

$A25,342 — $A37,274

DIVISION OF MINERAL ENGINEERING
CLAYTON VIC

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Mineral Engineering is a member of the Institute of Energy and Earth Resources.

FIELD: Mathematical Modelling.

GENERAL: The Division of Mineral Engineering, located at Clayton, in Melbourne, forms part of the Institute of Energy and Earth Resources. The Division conducts theoretical, experimental and application studies aimed at developing, improving and controlling industrial processes. Particular emphasis is placed on the treatment and handling of ores and mineral products.

DUTIES: In seeking its objectives, the Division undertakes extensive mathematical modelling of various operations in extractive metallurgy. Current activities include deterministic models of bubbles in fluidized beds, heat and mass transfer in various packed bed configurations, the sintering of ores, direct reduction of iron ores, etc. In all cases, a heavy emphasis is placed on proper validation of the models against experimental measurements.

The Division is expanding its modelling interests to include multi-phase flow systems with flow in 3 dimensions and concurrent chemical reactions, as found in various pyrometallurgical processes. The Division is seeking a chemical engineer, mechanical engineer or physicist with experience and interest in such numerical modelling. The appointee will undertake research on the development and validation of numerical models, initially of certain high temperature gas/slag/metal systems.

The Division is well equipped with computer systems and may, in addition purchase appropriate software packages for multi-dimensional flow computations.

QUALIFICATIONS: A PhD degree or equivalent qualifications plus research experience in an appropriate discipline, eg. Chemical Engineering, Metallurgy, Physics, together with experience relevant to the research to be undertaken.

Outstanding applicants may be considered for appointment at a higher classification.

TENURE: Indefinite with Australian Government superannuation benefits available.

APPLICATIONS: Quoting reference No A1537, should be directed to:

The Chief
CSIRO Division of Mineral Engineering
PO Box 312
CLAYTON VIC 3168
AUSTRALIA

By July 13, 1984.

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER (W1043)A

CENTRAL BIRMINGHAM HEALTH AUTHORITY
THE CHILDREN'S HOSPITAL

SENIOR BIOCHEMIST/SCIENTIST

Applications are invited from suitably qualified graduates to work in the CELL CULTURE/ENZYMOLOGY section of the Department of Clinical Chemistry. This section is part of the laboratory which provides a Regional service for postnatal diagnosis of inherited metabolic disorders.

This is a specialised post and the work involves enzyme and metabolite assays in blood, fibroblasts and other tissues. Previous experience with cell culture techniques and enzymology, although not essential, will be an advantage.

Potential applicants are encouraged to visit the Department by prior arrangement with the Head of Department, Mrs Anne Green (021 454 4851 ext 290). Application forms/Job descriptions available from Personnel Officer, The Children's Hospital, Ladywood Middleway, Birmingham B16 8ET. Closing date for receipt of applications — 6th July 1984.

(2307)A

Senior Positions in Biochemistry and Nerve Cell Biology

The Sandoz Institute for Medical Research invites applications for the positions of Head of Laboratory (one in Biochemistry and one in Cell Biology & Cell Culture) tenable from 1 January 1985.

The Institute will be housed in well-equipped and spacious new laboratory accommodation which is being built within the precincts of University College London, with which strong academic links will be forged. The scientific staff will be up to 25–30 by 1987.

The Institute will embark on a programme of basic research in neurobiology, concentrating initially on mechanisms involved in nociception, with the long-term aim of developing new compounds of potential therapeutic value. Initially there will be six laboratory groups (Medicinal Chemistry, Biochemistry, Neuropharmacology, Cell Biology and Cell Culture, Immunology, Cellular Electrophysiology) which will collaborate on a range of individual projects.

Applicants for both positions need to have proven ability to organize and supervise the running of a research laboratory, and to contribute original ideas to a multidisciplinary research effort. Enthusiasm for interdisciplinary collaboration is essential.

Candidates for the Biochemistry position should have experience in the field of receptor-regulated mechanisms and/or the isolation and characterization of membrane proteins.

Candidates for the Cell Biology position should have general experience in cellular neurobiology and neuronal cell culture techniques, preferably with an interest in the biology of sensory neurons.

Salary negotiable, plus comprehensive benefit package including car. Assistance with relocation if required.

Applications by 16 July 1984, including cv and names of three referees, to Professor H.P. Rang, FRS, Director, Sandoz Institute for Medical Research, Department of Pharmacology, University College London, Gower Street, London WC1E 6BT (Telephone 01-388 5314), from whom further information can be obtained.

(2302)A

SANDOZ

Southampton THE UNIVERSITY

POST-DOCTORAL RESEARCH FELLOW
Department of Biology

Applications are invited from plant taxonomists to work with Dr F A Bisby and Dr R J White for three years commencing 1 October 1984. The collaborative project, supported by SERC and Biosis UK Ltd, involves experiments with disseminating taxonomic information from a computer database. The successful applicant will have a recent PhD and an interest in applying classical techniques in morphology, anatomy and nomenclature to the legume tribe Vicieae.

Starting salary £7,190 (under review) with annual increments and USS benefits.

Further information may be obtained if required from Dr R J White, Biology Department, Southampton University. Applications with curriculum vitae and names of two referees should be sent to Mr D A S Copland, Staffing Section, The University, Highfield, Southampton SO9 5NH as soon as possible, and not later than 20 July 1984. Please quote reference number 2052. (2323)A

THE UNIVERSITY OF WESTERN AUSTRALIA
PERTH
LECTURER IN ZOOLOGY (MAMMALIAN ECOLOGY) (FIXED FERM)

Applications are invited from suitably qualified persons for appointment for three years with some prospects of continuation to a Lectureship in the Department of Zoology. The Department has a tradition of marsupial studies in this appointment wishes to emphasize marsupial population biology. Exerpertise in mammalian population biology is sought; previous marsupial experience is not required. The Department runs a number of field stations suitable for the study of marsupial populations. The appointee will lecture to undergraduates generally and in a specialist unit, undertake research, and will be encouraged to lead graduate students.

Current salary range: $A24353-$A31994 per annum. Benefits include superannuation, fares to Perth for appointee and dependent family and removal allowance. Conditions of appointment will be specified in any offer of appointment which may be made as a result of this advertisement.

Applications in duplicate stating full personal particulars, qualifications and experience and the names and addresses of three referees, should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia 6009, by 21 July 1984. (W1059)A

UNIVERSITY OF LONDON
INSTITUTE OF PSYCHIATRY
The Bethlem Royal & The Maudsley Hospitals, London
LECTURESHIP IN OLD AGE PSYCHIATRY

Applications are invited for a second post of Clinical Lecturer in the newly established Section of Old Age Psychiatry. The applicant will be expected to initiate new research and teaching of the subject and to assist the Professor in administrative and clinical duties.

The post is open to suitably qualified psychiatrists or clinical psychologists. Psychiatrists should possess the MRC Psych or a higher postgraduate degree and would have an Honorary Senior Registrar contract. Clinical psychologists should possess an appropriate postgraduate qualification. A commitment to the social, psychological and scientific problems of old age is essential but a flexible view will be taken of what constitutes relevant experience, more emphasis being laid on academic track record than on formal training in the field.

Salary within the range appropriate form the discipline.

Applications should be in the form of a curriculum vitae (6 copies) with the names of two referees. They should be sent by 14th July to Professor Raymond Levy, Institute of Psychiatry, De Crespigny Park, London SE5 8AF from whom further particulars may be obtained.

(2364)A

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)
POSTDOCTORAL RESEARCH FELLOW
DEPARTMENT OF PHYSIOLOGY

Required for 2 years for work on the electrophysiology and pharmacology of amino-acids in brain slices. A background in electrophysiology would be an advantage, though not necessarily using slices. Initial emoluments up to ££8,376 pa.

Application form and further details from the Establishment Officer (Ref: FP), St George's Hospital Medical School, Cranmer Terrace, London, SW17 0RE. Closing date: 4th July. (2352)A

INSTITUTE OF CANCER RESEARCH
POST-DOCTORAL FELLOW

is required at the Institute's Chemical Carcinogenesis Section, Chester Beatty Laboratories, Fulham Road, SW3, for a project involving the investigation of the mechanisms by which polycyclic aromatic hydrocarbons are activated by metabolism in rodent and human cells and tissues. Appointment is for two years in the first instance. Salary in range £7,190-£8,975 pa, plus London Allowance of £1,186 pa.

Applications in duplicate with the names of two referees to the Personnel Officer, Institute of Cancer Research, 34 Sumner Place, London, SW7 3NU, quoting ref 300/G/50. (2354)A

TRANSLATORS, Russian to English, work at home in free time. Specialists in fisheries, aquatic biology and soil science reply to Scripta Technica (subsidiary to John Wiley & Sons, Inc. Publishers), 7961 Eastern Avenue, Silver Spring, MD, 20910. (NW597)A

UNIVERSITY OF ST ANDREWS
DEPARTMENT OF PHYSIOLOGY & PHARMACOLOGY
TEMPORARY LECTURER

Applications are invited for a Temporary Lectureship (three years) In addition to teaching duties, the successful candidate will be expected to carry out research within the field of "muscle energetics, metabolism and locomotion of Antarctic animals'. This work is supported by an award from the NERC Antarctic Research Special Topics Programme to Dr I A Johnston.

Some relevant postdoctoral or equivalent research experience in muscle research is essential. Excellent research facilities and support are available for studies of muscle physiology and biochemistry.

Salary at appropriate point within range £7,190 to £8,530 per annum (under reveiw), plus USS.

Further particulars are available from the Establishments Officer, The University, College Gate, St Andrews, Fife KY16 9AJ, to whom applications (two copies preferably in typescript) with the names of three referees, should be sent to arrive not later than 7 July 1984. (2891)A

KUWAIT
UNIVERSITY OF KUWAIT HEALTH SCIENCE CENTRE
FACULTY OF MEDICINE

Appointment in Anaesthesia
The Faculty wishes to appoint a Professor or an Associate Professor to lead the Division of Anaesthetics at the University Teaching Hospital (Mubarak Hospital). The successful applicant will have to be an established consultant, preferably at a University Undergraduate Teaching Hospital. The principal tasks will be to develop a high quality of anaesthetic service, and postgraduate teaching programmes and participate in undergraduate teaching programmes. Facilities for research have been set aside in the Department of Surgery and applications for research funds will be favourably considered.

The successful applicant will also be appointed as Head of the Clinical Department of Anaesthetics by the Ministry of Health and sit on the Discipline Committee for Anaesthesia for the State of Kuwait. *He may, in due course, be appointed Chairman.* The minimum duration of appointment will be 2 years.

Requirements for Appointment
Applicants for Professorship or for Associate Professorship should possess a PhD, or higher professional medical qualification (e.g. MRCP) in their respective speciality and have teaching experience and conducted and published research in their field. Associate Professors should have 9 years' experience past M.B., 4 as an Assistant Professor or its equivalent, i.e. Lecturer.

Conditions of Appointment
Salaries: Total monthly salaries will be within the following scales according to qualifications and experience (1 KD = £2.1, US$2.91 approx). Professor with clinical appointments: KD 1210-1370 (8 increments); Associate Professor with clinical appointments: KD 989-1149 (8 increments).

Clinical supplements: In addition to the above University salaries there will be a monthly clinical supplement paid by the Ministry of Public Health for ten months' a year to medical school staff with clinical service commitments. These are: Professor KD 200; Associate Professor KD 150.

Gratuity: There is a gratuity of one month's basic salary for each year employed payable on termination of contract.

Housing: Suitably furnished, air-conditioned accommodation, electricity and water are provided free of charge.

Medical Care: Free comprehensive treatment is available in Kuwait under the State Health Service.

Travel: Air tickets are provided from the country of recruitment for the appointee, spouse and up to three dependent children under 20 years, there after, return air tickets are issued annually to the country of citizenship or permanent residence. On termination of contract, air tickets are provided to the country of recruitment. A baggage and freight allowance is also provided. In addition, travel expenses for attending one scientific meeting a year are paid by the University up to KD 500 per year.

Vacation: Sixty days paid annual leave and various national holidays.

Education: This is normally provided free in State schools where the instruction is in Arabic. Staff who have to send their children to non-Arabic schools in Kuwait will have a part of the tuition fees of up to a maximum of three met by the University.

Taxation: There is no income tax in Kuwait. Currency is transferable without restriction.

Method of application:
Curriculum vitae in duplicate, which should include personal particulars qualifications with dates, career history, teaching experience, research accomplishments and clinical experience, should be sent together with the names of three referees to the Dean, Faculty of Medicine, University of Kuwait Health Science Centre, PO Box 24923, Safat Kuwait, to arrive no later than one month from the date of Advertisement.

Enquiries: Further particulars may be obtained from PROFESSOR M. D. VICKERS, Welsh National School of Medicine, Department Anaesthetics, Health Park, Cardiff, CF4 4XN, who is advising the Medical School on the appointment.

(W1051)A

THE AUSTRALIAN NATIONAL UNIVERSITY

RESEARCH SCHOOL OF CHEMISTRY

POSTDOCTORAL RESEARCH POSITIONS

Applications are invited for postdoctoral research positions in the Research School of Chemistry. Current major research interests in the School are:

Organic Chemistry (Professor A L J Beckwith, Professor L N Mander, Mr R W Rickards, Dr J K MacLeod, Dr L Radom): including free radical reactions; mechanistic and synthetic organic chemistry; reactive intermediates; organic and bio-organic chemistry of bilogically active compunds; ICR and mass spectrometry; ESR spectroscopy; theoretical organic chemistry.

Inorganic Chemistry (Professor B G Hyde, Professor A M Sargeson, Dr M A Bennett, Dr G B Robertson, Dr S B Wild): including solid state inorganic chemistry; synthesis, structure and reaction mechanisms of transition metal complexes; biomimetic chemistry; organo-transition metal chemistry; X-ray crystallography; resolution and reactions of chiral arsines and phosphines, Physical and Theoretical Chemistry (Professor D P Craig, Dr J Ferguson, Dr R Bramley, Dr T R Welberry, Dr D J Evans): including molecular and crystal theory; spectroscopy and photochemistry; photophysics and magnetic resonance; X-ray diffraction and theoretical studies of disordered materials; liquid state chemical physics.

There are three levels of appointment, Postdoctoral Fellow, Research Fellow and Senior Research Fellow. The level appropriate for each appointee will be determined by the University and will depend on qualifications and experience. Appointment as Postdoctoral Fellow will be for one or two years; appointment as Research Fellow and as Senior Research Fellow will be for three years in the first instance. Salary will be within the ranges: Postdoctoral Fellow $A22,041 – 25,249 pa; Research Fellow $A25,571 – 33,594 pa; Senior Research Fellow $A35,720 – 42,607 pa. Current exchange ranges $A1: Stg 64p: $US 90c. Reasonable travel expenses are paid and assistance with housing is given for an appointee from outside Canberra. Superannuation benefits are available. Maternity leave is available.

Further particulars on the appointments may be obtained on request to the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF,or to the Acting Registrar, Australian National University, GPO Box 4, Canberra, ACT 2601, Australia. There is no application form. Applicants should supply to the Acting Registrar of the University by 24 August 1984 a curriculum vitae, list of publication, and statement of research interests together with two passport-sized photographs, the names and addresses of three academic referees and the probable date on which the Postdoctoral Fellowship, Research Fellowship or Senior Research Fellowship, if awarded, could be taken up.

The University is an equal opportunity employer. (W1056)A

THE MEDICAL COLLEGE OF ST BARTHOLOMEW'S HOSPITAL

RESEARCH ASSISTANT

Applications are invited for an MRC-funded research position which it is hoped will be available for commencement in October, 1984 for 3 years. The project, under the supervision of Dr P.J. Lowry and Dr G. Gillies in the Protein Hormone Unit, is to investigate the control of release of hypothalamic corticotropin releasing factors employing the techniques of hypothalamic neurone culture, isolated pituitary cell bioassay, radioimmunoassay, immunoradiometric assay and chromatography, including HPLC. Starting Salary (Range 1B) £6,310 + £1,186 London Allowance. Applicants should possess, or hope to obtain a good Honours degree in Pharmacology, Biochemistry, Physiology or some other relevant subject.

Applications may be made in writing, enclosing a Curriculum Vitae to The Secretary, St. Bartholomew's Hospital Medical College, West Smithfield, London EC1A 7BE, quoting reference RES.16.

Closing Date: 28th June 1984. (2355)A

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF RADIATION ONCOLOGY

Applications are invited for the post of

UNIVERSITY RESEARCH ASSISTANT/SENIOR RESEARCH ASSISTANT/RESEARCH ASSOCIATE

in the recently formed Department of Radiation Oncology. The person appointed will assist in the development of human monoclonal antibodies and will be required to operate the Departments FACS 420 machine. Preference will be given to candidates with previous experience of flow cytofluorimetry and cell sorting.

Salary on the scale £6,310 – £11,615 per annum.

Applications, together with the names of three referees, should be received not later than 22 June, 1984, by the Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/537. (2308)A

UNIVERSITY OF OXFORD

NUFFIELD DEPARTMENT OF CLINICAL BIOCHEMISTRY

TEMPORARY RESEARCH TECHNICIAN

A short-term vacancy has arisen for a technician (M.L.S.O. Grade) to assist with studies on the regulation of insulin secretion. Experience of tissue culture would be an advantage. The appointment is for six months; however, the post may lead to re-appointment.

Applications including curriculum vitae and names of two referees should be sent to Dr S.J.H. Ashcroft, Department of Clinical Biochemistry, John Radcliffe Hospital, Headington, Oxford OX3 9DU, (Telephone: 0865 817377), from which further details may be obtained. (2345)A

Canadian Institute for Theoretical Astrophysics/ Institut Canadien D'Astrophysique Theorique

University of Toronto

DIRECTOR

The University of Toronto is seeking to appoint a tenured full professor of theoretical astrophysics. The successful candidate will be a scientist of established stature who must also possess both vision and administrative ability. In addition to his own research activities, his primary responsibility, at least initially, will be to ensure the growth of the institute, CITA, in substance and concept by providing scientific leadership and administrative guidance in collaboration with the national Council of the institute. The professorship will be in CITA, within the School of Graduate Studies, with cross-appointments foreseen in the Department of Astronomy and/or Physics. Send letter, CV and arrange for letters from three persons commencing on suitability for the described position to reach: Chairman, CITA Council, Canadian Institute for Theoretical Astrophysics, University of Toronto, Toronto, Ontario M5S 1A7 at the earliest possible time, and not later than 1 September 1984. In accordance with the regulations of Canadian immigration, preference will be given to Canadian citizens and permanent residents.

(NW605)

HILL FARMING RESEARCH ORGANISATION

Scientific Officer

Applications are invited for the post of Scientific Officer in our Systems Studies programme at Hartwood Research Station.

The Hill Farming Research Organisation is an Equal Opportunities Employer.

The Principal duty of the post will be responsibility for the day to day management of sheep systems studies at Hartwood. The successful candidate will be directly responsible to the project leader and will be expected to collect and record the necessary data.

Qualifications: A degree in Biology or Agricultural Science.

Salary: According to qualifications within the scale £5,682 to £7,765.

There is a non-contributory terminal salary superannuation scheme. Male members of staff must pay 1½% of salary in respect of widows' pension rights.

22 days annual leave

Application forms and further information may be obtained from the Assistant Secretary, Hill Farming Research Organisation, Bush Estate, Penicuik, Midlothian EH26 0PY to whom they should be returned not later than 29 June 1984.

(2348)A

WESTMINSTER MEDICAL SCHOOL
HISTOPATHOLOGY DEPARTMENT

Applications are invited for a

RESEARCH POST

which is based at the Vincent Square Research Laboratory and funded for two years. The research project is to evaluate immunocytochemical markers in soft tissue tumours.

Experience in histopathology techniques is essential, whilst a knowledge of immunocytochemical techniques, although not essential, would be useful. Salary on the MLSO scale with conditions of service comparable to Whitely Council.

Further information may be obtained by telephoning Dr Mary Leader on 01-828 9811 ext 2301. Curriculum vitaes should be sent together with the names and addresses of two referees to Dr Mary Leader, Histopathology Department, Westminster Medical School, 17 Horseferry Road, London SW1P 2AR.

Closing date for applications: June 30th. (2359)A

THE UNIVERSITY COLLEGE OF WALES ABERYSTWYTH
POSTDOCTORAL RESEARCH: MICROBIAL PHYSIOLOGIST

Applications are invited for a Postdoctoral post funded by the SERC Biotechnology Directorate, and concerned with biotransformations by species of Clostridium. The applicant will join an established research group led by Professor J G Morris, studying fermentation processes in anaerobic bacteria maintained in batch and continuous flow culture. Informal enquiries may be made of Dr Douglas Kell by telephoning (0970) 3111, Ext 3055.

The appointment will be for up to 3 years, depending on the starting date, and will commence not later than 1 October 1984. The salary scale is £7190 to £11615 per annum (under review).

Application forms and further particulars may be obtained from the Staffing Officer, The University College of Wales, Old College, King Street, Aberystwyth, SY23 2AX (Tel (0970) 3177, Ext 207). Closing date for applications: 2 July 1984.(2336)A

Public Service Commission of Canada | Commission de la Fonction publique du Canada

Research Scientist, Earth Structure Studies

Energy, Mines and Resources
Earth Physics Branch
Ottawa, Ontario

We require a geophysicist/geologist to conduct field investigations and research studies into the nature and structure of major geological features throughout the Canadian landmass. Emphasis will be on the application of deep seismic reflection techniques, including vibrosesis, and regional three-dimensional seismic refraction methods. Other geological and geophysical methods will be incorporated as necessary. Field investigations will be carried out in all parts of Canada, from the east and west coasts to the Arctic Ocean Basin. Research studies will demand extensive use of state-of-the-art computer-based processing and international methods.

You require graduation with a doctorate degree from a recognized university in geophysics, geology, physics or a related field, or a lesser degree with evidence of research experience and productivity equivalent to that of a doctorate degree. Extensive experience in the processing and interpretation of multifold seismic reflection data is also required. Knowledge of either English or French is essential.

We offer a salary ranging from $26,834 to $49,913 commensurate with your qualifications and experience. Effective 23 June 1984, the revised salary range will be $28,176 to $52,409.

Forward your application form and/or résumé, quoting reference number S-84-31-5523-JG47(G26), to:
Joan Girling (613) 593-5331

UNIVERSITY OF BRISTOL

DEPARTMENT OF BOTANY AND ZOOLOGY

POST-DOCTORAL RESEARCH ASSISTANT

To investigate the microstructure of algal communities on estuarine mud surfaces, and to examine the effects of grazing snails on these communities and on surface stability. The research will utilize scanning electron microscopy and will involve the development techniques of frozen-hydrated specimen preparation. Research will be undertaken in collaboration with Dr R M Crawford and Dr C Little.

Experience in electron microscopy and some knowledge of microalgae is essential. Salary will be on the 1A salary scale. The appointment will be for two years starting on 1 October 1984.

Applications (citing 2 referees) to Dr R M Crawford, Department of Botany, University of Bristol, Bristol BS8 1UG by 1 July 1984. (2884)A

University of California Lawrence Berkeley Laboratory Announces an opening 1 January 1985 for Associate Laboratory Director and Head of Nuclear Science Division

The Lawrence Berkeley Laboratory is a multi-purpose research laboratory funded by the Department of Energy. Its Nuclear Science Division conducts a multi-million dollar research program in low, medium and high-energy nuclear physics. The Head of the Division has primary responsibility for the leadership and management of this program under the general direction of the Deputy Director for General Sciences and the Laboratory Director. As an Associate Director of the Laboratory, the incumbent will also participate in formulating the research policy and long-term direction of the Laboratory as a whole. Candidates must have had significant experience as practicing nuclear physicists and be of the general calibre of persons holding senior tenure positions in major research institutions. The successful applicant would be expected to serve as Associate Director and Division Head for an initial term of 3 to 5 years, subject to renewal for further terms by mutual agreement.

The Laboratory is seeking a respected and energetic nuclear physicist willing to play a strong leadership role at a challenging time. Qualifications must be such that it will be natural to consider him or her for a tenured appointment in the Department of Physics on the Berkeley campus of the University of California, as well as at the Laboratory. Interested applicants should submit a curriculum vitae, together with the names of three references to: Dr J.D. Jackson, Chairman, Nuclear Science Search Committee, c/o Employment Office, LAWRENCE BERKELEY LABORATORY, 1 Cyclotron Road, Berkeley, CA94720. Refer to Job A/2947. An Equal Opportunity Employer M/F/H. Deadline for applications: August 31, 1984. (NW594)A

KINGDOM OF SAUDI ARABIA
KING SAUD UNIVERSITY
COLLEGE OF AGRICULTURE
RIYADH, SAUDI ARABIA

Qualified personnel are invited to apply for the following posts of FACULTY MEMBERS (Professors, Associate Professors, Assistant Professors), LECTURERS, DEMONSTRATORS, RESEARCH ASSISTANTS and TECHNICIANS for the academic year 1984 -1985.

Department	Specialization	Qualification
I. Staff members:		
(1) Food Science	a. Human nutrition metabolism. b. Dairy technology. c. Food analysis.	Ph.D., Teaching experience, Arabic speaking.
(2) Animal Science	a. Poultry nutrition.	-do-
(3) Plant Production	a. Cytogenetics.	-do-
(4) Ag. Economics & Rural Sociology	a. Farm management. b. Marketing of agricultural products.	Ph.D., Teaching experience, Associate or Professors only, Arabic speaking.
(5) Home Economics & Nutrition (Female only)	a. Textiles and costumes.	Ph.D., Teaching experience, Arabic speaking.
II. Lecturers:		
(1) Home Economics and Nutrition (Female only)	a. Plant production (ornamentals) b. Plant production (field crops).	M.Sc., Teaching experience, Arabic speaking.
(2) Plant Production	a. Plant production (vegetable crops).	-do-
(3) Animal Production	a. Animal production	-do-
III. Demonstrators:		
(1) Food Science	a. Fish and meat technology. b. Food microbiology. c. Food analysis.	B.Sc. "B" average or higher, past experience in teaching, research is preferred, Arabic speaking.
(2) Plant Production	a. Horticulture (vegetable crops).	-do-
(3) Agricultural Engineering	a. Agric. Engineering.	-do-
IV. Research Assistants:		
	a. Food microbiology. b. Food chemistry and analysis. c. Horticulture (Pomology). d. Field Crops (Breeding).	Preferably M.Sc. with research experience in the field of specialization.
V. Technicians:		
	a. Human nutrition. b. Cereal technology. c. Analytical chemistry in the field of food science.	Experience in field of work, conducting and operating laboratory equipment. Experience and training in operating food and nutrition analyses equipment preferably IR, AAA, AA, GLC, HPLC. Good knowledge of English language.

Please apply to:

CSIRO

AUSTRALIA

Molecular Biologist

$A25,342 — $A37,274

DIVISION OF MOLECULAR BIOLOGY
NORTH RYDE NSW

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Molecular Biology is a member of the Institute of Animal and Food Sciences.

GENERAL: The Division, with a staff of nearly 100, has research programs in Animal Cell Growth and Development, DNA Maintenance and Modification and Gene Technology.

DUTIES: To conduct and direct ongoing research in the area of gene cloning and expression, with particular emphasis on the molecular genetic manipulation of prokaryotic and eukaryotic micro-organisms for the purpose of metabolic modification or the production of vaccine antigens (and other polypeptides of interest).

QUALIFICATIONS: A PhD degree or equivalent qualifications in biochemistry or a related discipline and preferably with relevant post-doctoral training. Broad experience in the various facets of molecular biology at the nucleic acid, protein and immunological levels would be an advantage.

TENURE: Indefinite with Australian Government superannuation benefits available.

APPLICATIONS: Stating full personal and professional details, the names of at least two referees, and quoting reference No A3782, should be directed to:

The Chief
CSIRO Division of Molecular Biology
PO Box 184
NORTH RYDE NSW 2113
AUSTRALIA

By July 13, 1984.

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER (W1044)A

Structural Cellular/ Molecular Biologist

Small-Angle Neutron Scattering

The University of Missouri-Columbia, Division of Biological Sciences invites applications for a tenure-track position in the area of structural cellular and molecular biology at the assistant or associate professor level, dependent on qualifications. The position requires undergraduate and graduate teaching in cellular and molecular biology and a biological research emphasis that relies heavily on small-angle neutron scattering. Applicants must have had extensive experience, and demonstrated excellence in small-angle neutron scattering. The small-angle neutron scattering spectrometer at the University of Missouri Research Reactor in Columbia is one of only a few such instruments in the U.S. and is the highest flux steady-state reactor at any American University. The successful candidate will interact with a strong University faculty with interest in biological structures: nucleic acids, membranes, proteins, protein-nucleic acid complexes, and organelles. Modern biophysical instrumentation already on the Columbia campus include: NMR (300, 200 and 90MHz); scanning and transmission electron microscopes; mass, fluorescence, atomic absorption, and small-angle x-ray scattering spectrometers.

Applicants should submit by, August 20, 1984, curriculum vitae, statement of research and teaching interest, and names of three references to: Paul F. Agris, Chairman, Search Committee, University of Missouri, Biological Sciences, Tucker Hall, Columbia, MO 65211, 314-882-6426.

An Affirmative Action/Equal Opportunity Employer.

(NW602)A

Canadian Institute for Theoretical Astrophysics/ Institut Canadien D'Astrophysique Theorique

University of Toronto

SHORT TERM FELLOWS AND VISITING APPOINTMENTS

The community of theoretical astrophysicists in Canada, in association with the University of Toronto and with funding from the Natural Sciences and Engineering Research Council, has recently established a national centre for theoretical astrophysics. Pending appointment of a Director, after which longer term appointments will be considered, applications are invited for short term fellowships. These are intended to encompass visiting appointments at any level of seniority, and will be for a mutually convenient duration of up to one year, beginning immediately. Also included are postdoctoral and research associate positions, for a one year term with the possibility for renewal; these are likely to begin in the fall of 1984. Although candidates with interests spanning the whole spectrum of theoretical astrophysics are encouraged to apply, the Council of the institute will be attempting to concentrate interests at any given time to encourage interactions between Canadian and foreign investigators. Send letter, CV and arrange for three letters of recommendation to be sent to: Chairman, CITA Council, Canadian Institute for Theoretical Astrophysics, University of Toronto, Toronto, Ontario M5S 1A7 at the earliest possible time. Initial contact by letter or telephone (416-978-4165/6840) is encouraged for established scientists contemplating visits. In accordance with immigration regulations, certain portions of this advertisement are directed in the first instance to Canadian citizens or permanent residents. (NW606)A

Chair and Professor, Division of Nematology

Nominations and applications are invited for an 11-month, tenured position at the University of California at Davis to serve as Chair of the Division of Nematology. The Chair will also have some research, teaching, and student advising responsibilities. The usual appointment as Chair is for five to seven years, subject to renewal on review. Upon completion of service as Chair of the Division, the faculty member may return to full-time teaching and research. The position is available September 1, 1984.

Qualifications include a Ph.D. with experience in Nematology or closely related discipline, proven leadership and management qualities, and a record of scholarly and academic achievement.

Applicants should submit a *curriculum* vitae with a bibliography and reprints of pertinent publications, statement of research, teaching, and administrative interests and background in each, and the names and addresses of at least three references to: Dr. R. K. Webster, Acting Associate Dean and Search Committee Chair, College of Agricultural and Environmental Sciences, Dean's Office, 228 Mark Hall, University of California, Davis, CA 95616 USA. Applications should be received by August 1, 1984. Applications received later will not be considered unless the position is reopened for recruitment.

The University of California is an affirmative action/equal opportunity employer. (NW603)A

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF CHEMISTRY

RESEARCH ASSOCIATE

Applications are invited for the above NERC funded post to work with Dr J A Kerr on Kinetic and Mechanistic Studies of the photo-oxidation of Aldehydes under Simulated Atmospheric Conditions. Part of a research programme aimed at obtaining a better understanding of the chemistry of the lower atmosphere.

There will be an opportunity to register for a higher degree.

The post is tenable for up to 3 years from 1.10.84. Salary on the Research Associate 1B scale £6310 — £8530 plus superannuation. Starting point near the bottom of the scale.

For further particulars phone 021-472 1301 Ext 2559 quoting reference F3.

No formal application form. Three copies of application, including full Curriculum Vitae and naming three referees to Assistant Registrar (Science and Engineering), P O Box 363, Birmingham, B15 2TT by 29 June 1984. (2370)A

Southampton THE UNIVERSITY

NEW BLOOD LECTURESHIP IN GEOLOGY
(Re-advertisement)

Applications are invited for the post of Lecturer in Geology with special emphasis on the geochemistry of fluid-rock interactions as applied to metals and/or hydrocarbons. Applicants with interests in fields such as hydrothermal alteration, petroleum generation and migration, diagenesis, pore fluids, fluid inclusions or stable isotopes will be particularly welcome. This new blood post is intended to reinforce the research interests of the Department in applied geology. Salary scale: £7,190 × £450 (15) — £14,125 per annum (under review). The initial salary will depend on qualifications and experience. Further particulars may be obtained from Mr D. A. S. Copland, The University, Southampton SO9 5NH to whom applications (7 copies from United Kingdom applicants) should be sent not later than 2 July 1984, quoting reference No: 2039.

RESEARCH ASSOCIATE

To participate in formulation and solution of mathematical, statistical, and computer science problems in the analysis of macromolecular sequences. Candidates should have expertise in nucleic acid and protein sequences, the genetic code, probability, statistics, optimization theory and computer programming, and a master degree in mathematics. Salary $16,000 per year. Job site: Los Angeles area educational institution. Send Ad and curriculum vitae to Job #4126, PO Box 865, Sacramento, CA 95804 not later than June 29, 1984. (NW601)A

UNIVERSITY OF OXFORD

SIR WILLIAM DUNN SCHOOL OF PATHOLOGY
South Park Road,
Oxford OX1 3RE

MOLECULAR BIOLOGY OF MACROPHAGES

POST DOCTORAL RESEARCH
position Grade 1A
Salary: £7,190 — £11,615

A talented, well trained Molecular Biochemist is needed to initiate research into gene structure and expression in Macrophages. My group at the Sir William Dunn School of Pathology is supported by an MRC programme grant and works on macrophages secretion products, plasma membrane differentiation antigens and receptors.

The appointment, starting as soon as possible, is likely to be for at least four years.

Applications enclosing curriculum vitae and the names and addresses of two referees should be sent to Dr S Gordon, Sir William Dunn, School of Pathology, South Park Road, Oxford OX1 3RE. (2878)A

A challenging career in Diagnostic Reagents

LABORATORY HEAD

c.£15,000: Dartford, Kent

We are seeking to consolidate our activities in the field of Diagnostic Reagents by establishing a new laboratory within our Central Analytical Division at Dartford.

Managing a small team of experienced staff, you will be responsible to senior management for ensuring that the laboratory meets its major objectives, which include:

- Developing and introducing reliable quality control methods and procedures
- Establishing quality control standards and specifications
- Assessing the stability of products
- Assembling data for product registration
- Conducting technical audits
- Handling customer complaints

Qualified to honours degree level in a biological science, you should have several years' post-graduate experience in a range of applied techniques ideally involving diagnostic reagents. Experience of analytical development and quality assurance together with the ability to demonstrate good man-management and communication skills are also essential requirements.

The Wellcome Foundation Limited is a major group of pharmaceutical and chemical companies with headquarters in the UK and a turnover close to £700m.

Excellent benefits include five weeks' holiday, first class sports and social facilities and generous assistance with relocation expenses where appropriate.

Please write or telephone for an application form to Steve Menear, Personnel Officer, The Wellcome Foundation Limited, Temple Hill, Dartford, Kent. Tel. Dartford (0322) 23488, ext 2025. (2366)A

Wellcome

UNIVERSITY OF LONDON
ST GEORGE'S HOSPITAL MEDICAL SCHOOL

DEPARTMENT OF PHARMACOLOGY AND CLINICAL PHARMACOLOGY

MRC POST DOCTORAL POSITION IN CYCLIC NUCLEOTIDE RESEARCH

A 3-year MRC funded position (Ref TC 14) is available to work with Dr A C Dolphin on biochemical and/or electrophysiological aspects of the role of cyclic nucleotides in modulation of neuronal cell function. Immunocytochemical techniques will also be used. Experience in tissue culture would be an advantage, as it is envisaged that neuronal cells in culture will be used for much of the work.

The salary will be on the 1a scale, £7190: £7630: £8080 plus £1186 London allowance.

Applications, including curriculum vitae and the names of two referees should be sent to Dr A C Dolphin, Department of Pharmacology and Clinical Pharmacology, St George's Hospital Medical School, Cranmer Terrace, London, SW17 0RE.

Further details can be obtained by writing to Dr Dolphin or by telephoning (01-672 1255 Ext. 4688). (2888)A

Head of Literature/ Information Services

A unique Career opportunity

Merck Sharp & Dohme Research Laboratories are establishing a Neuroscience Research Centre on a greenfield site near Harlow, Essex. The Centre will be one of the world's largest laboratories dedicated to Neuroscience research encompassing Medicinal Chemistry, Biochemistry and Pharmacology.

We are seeking to recruit an exceptional individual who will have the task of initially establishing, and ultimately managing, a research library and information service for approximately 200 research staff. Responsibilities will include the acquisition, organisation, classification and evaluation of books and periodicals combined with a computerised bibliographical and data base searching facility.

Applications are invited from men and women who have a 1st degree in either Chemistry or Biomedical Science and postgraduate qualification in information science combined with a minimum of 3 years experience managing a scientific research library.

If you are confident of being able to make a significant contribution to this prestigious research endeavour, then write enclosing full C.V. to Andrew Harley, Personnel Manager, Merck Sharp & Dohme Research Laboratories, Hertford Road, Hoddesdon, Herts EN11 9BU.

MSD MERCK SHARP DOHME (2893)A

Neuroscience Research Centre

Research Opportunities Medicinal Chemistry

Merck Sharp & Dohme Research Laboratories is a leading international pharmaceutical research organisation which is establishing a Neuroscience Research Centre on a 30 acre greenfield site near Harlow, Essex. The Centre will be one of the world's largest laboratories dedicated to neuroscience research initially focussing on the study of inhibitory chemical messengers in the brain and exploration of the functional role of neuropeptides in the control of emotion, appetite, memory and learning.

In preparation for the move to the Harlow site, the current eminent research team is to be expanded by the development of a Medicinal Chemistry group. In this respect the following positions have been created:

SENIOR RESEARCH CHEMIST Candidates for this career appointment should have a Ph.D in Chemistry with postdoctoral experience in organic synthesis.

POSTDOCTORAL FELLOW This appointment will be to carry out basic research in the peptide chemistry area. Experience of working in this field although advantageous, is not essential.

Our goal is to provide the facilities and compensations to enable the candidates appointed to devote their total endeavours to our research aims. If you feel that you meet our requirements write enclosing a full Curriculum Vitae stating current salary and listing three referees to: Andrew Harley, Personnel Manager, Merck Sharp & Dohme Research Laboratories, Hertford Road, Hoddesdon, Herts, EN11 9BU.

MSD MERCK SHARP DOHME (2894)A

Neuroscience Research Centre

Amgueddfa Genedlaethol Cymru — National Museum of Wales

Department of Botany

Research Assistant
CRYPTOGAMIC BOTANY

A Cryptogamic Botanist (non-bryological) is required to assist in the development and curation of collections in the Cryptogamic Section of the Department of Botany.

Applicants should have a broad taxonomic knowledge and a speciality in which he/she has the potential to make original contributions to taxonomy. The successful candidate will be appointed on the Research Assistant II (Curatorial Group F) salary scale (£6,133-£8,563) with the prospects of promotion to Research Assistant I (Curatorial Group E) salary scale (maximum salary £10,831), both salary scales under review.

Applicants must be unemployed.

Further particulars of the post may be obtained from the Secretary, National Museum of Wales, Cathays Park, Cardiff, CF1 3NP to whom applications should be submitted not later than 2 July 1984. (2351)A

THE INSTITUTE OF ZOOLOGY THE ZOOLOGICAL SOCIETY OF LONDON

LABORATORY TECHNICIAN

required to run a radioimmunoassay laboratory and to assist in studies on mammalian reproductive physiology. Candidates must have a training in biochemistry or endocrinology, at least 5 years' relevant experience and an H.N.C. or equivalent qualification. The appointment is for five years initially and salary, according to age, qualifications and experience, will be within the range £7794 — £8880 inclusive of London weighting allowance.

Please apply in writing by providing c.v. and names and addresses of two referees to the Establishment Officer, Zoological Society of London, Regent's Park, London NW1 4RY. (2338)A

MISCELLANEOUS

SPINCO ANALYTICAL CENTRIFUGE MODEL E

with Schlieren and UV optics (no scanner) to give away to *third world country*. Recipient must take over cost of transport to new location.

Inquiries to: Zürich 01 377 3403. (W1048)J

BEEBSTAT STATISTICS ON THE BBC MICROCOMPUTER

BEEBSTAT is a suite of eight programmes for standard statistical tests such as correlation and analysis of variance (several models). Data may be edited and transformed, kept on disc files and printed.

Details from Dominic Design Software, 19 Cressy House, Queens Ride, London SW13 0HZ. (2885)J

ASSISTANTSHIPS

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

Applications are invited for a POST-DOCTORAL RESEARCH ASSISTANTSHIP

in molecular biology for work on the development of plant gene vectors from virus replicons, involving DNA cloning and sequencing, transcriptional mapping, in vitro translation and plant cell transformation. The appointment will be for 2 years from 1 October 1984 with the possibility of renewal for a further period. Salary in the range £8376-£9761 including London Allowance.

Applications, with names of two referees, to Dr K W Buck and Dr R F A Coutts, Department of Pure and Applied Biology, Imperial College London SW7 2BB. (2121)P

Continued on page 2

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL LONDON

DEPARTMENT OF PHYSIOLOGY

LECTURESHIP

Applications are invited for a Lectureship in Physiology. Applicants should have an established record in research and would be expected to develop their own research interests.

The post will be held within the Joint Department of Physiology at University College London and this Medical School, where the post will be based.

Salary, according to age, qualifications and experience, within the range £8,376 — £15,312 inclusive of London Allowance.

Further information may be obtained from Professor J A Stephens, Sherrington School of Physiology, St Thomas's Hospital Medical School, London SE1 7EH tel 01-928 9292 ext 2241/7.

Applications in the form of a curriculum vitae, statement of research interests and the names and addresses of 3 referees should be sent to The Secretary, The Middlesex Hospital Medical School, London W1P 7PN by 19 July 1984. (2369)

UNIVERSITY OF YORK

DEPARTMENT OF BIOLOGY

RESEARCH ASSISTANT

Applications are invited for the post of research assistant in the Department of Biology, tenable for a period of three years from 1 September 1984, to work with Dr S M Bougourd on the effects of cancer chemotherapeutic drugs and tumour promoting agents on the chromosomes of human cell lines. The project is supported by the Yorkshire Cancer Research Campaign.

Applicants should have, or expect to obtain, a first or second class honours degree in a biological subject. Experience in cell culture techniques and cytogenetics is desirable but not essential. The successful candidate may have the opportunity to register for a higher degree.

Salary within the range £6,310 to £7,630 per annum, with USS.

Two copies of applications, with full curriculum vitae and naming two referees, should be sent to Registrar's Department (Appointments) University of York, Heslington, York YO1 5DD, by 11 July 1984. Further particulars are available. Please quote reference number 7120. (2321)A

UNIVERSITY OF OXFORD

Sir William Dunn School of Pathology

ADMINISTRATOR

Grade IIx.

Salary: £11,160-£15,085

Applications are invited from suitably qualified persons for the above post which it is hoped to fill from 1st September, 1984. The post carries superannuation in the USS. The Administrator, reporting directly to the Head of Department, is responsible for financial and budgetary control of the Department, for administration of the building, its services and research-support facilities and for the appointment and general supervision of technical, clerical and maintenance staff.

Further particulars may be obtained from Professor H Harris, Sir William Dunn School of Pathology, South Parks Road, Oxford OX1 3RE to whom applications, giving details of education, qualifications and experience, together with the names and addresses of two referees should be sent as soon as possible. There is no application forms. (2353)A

PAPUA NEW GUINEA INSTITUTE OF MEDICAL RESEARCH

RESEARCH FELLOWS IN EPEDIMIOLOGY, BACTERIOLOGY, VIROLOGY, IMMUNOLOGY and BIOSTATISTICS

The Papua New Guinea Institute of Medical Research is a Statutory Body of the Papua New Guinea Government set up to conduct research into the disease problems affecting Papua New Guineans. Major research programs have been established for the principal diseases of pneumonia, malaria, diarrhoea and malnutrition, problems common to the countries of the tropical world.

The Institute was founded in 1968. It has its headquarters at Goroka in the Eastern Highlands of Papua New Guinea, with a major branch at Madang, on the north coast, and a smaller branch in the Southern Highlands Province. The Institute has a new laboratory and office complex in Goroka and laboratories, including an insectary in Madang. It has a total staff of over 100. Data processing is carried out with computers in Goroka, Madang and Mendi in the Southern Highlands, each of which has its own manager.

Each of the major research programs has an epidemiological base in rural village communities, with associated laboratory studies. Each program is an integrated investigation of mortality, morbidity, aetiology, pathogenesis, genetics and specific risk factors in defined populations, with the evaluation of an innovative intervention aimed at prevention or early treatment of the disease under study. Each investigation is collaborative with colleagues from overseas laboratories and is carried out under the direction of the Institute Director. Apart from its principal funding from the Government of Papua New Guinea the Institute receives support for its programs from the World Health Organization and other international agencies.

The pneumonia research program investigates the major cause of death in children in Papua New Guinea and its integrated approach has been used as a model for similar programs elsewhere in the tropical world. The interaction between viruses, bacteria (principally *Streptococcus pneumoniae* and *Haemophilus influenzae*), the immune response and other host factors in determining the severity of ubiquitous acute respiratory infections and the spread from upper to lower respiratory tract is being investigated. A pneumococcal vaccine trial is in progress.

The diarrhoea research program investigates the aetiology of diarrhoea and the interaction between pathogens, including parasites (the Institute has its own parasitologist), and host and environmental factors. An attempt is being made to introduce oral rehydration methodology at the community level. The diarrhoea research program is being carried out in close collaboration with the pneumonia research program in both field and laboratory aspects.

The malaria research program is defining the epidemiology of malaria in a holo/hyperendemic area and investigating the causes for small-area variation. Parasites are being cultured in vitro and antigenic diversity investigated. The immune response to malaria is being dissected. The ultimate thrust of the program is the development, in collaboration with colleagues overseas, of antimalarial vaccines derived from defined antigens and in establishing populations suitable for the field evaluation of such vaccines.

Applications are sought for the following positions:

1. Research Fellow in Epidemiology in the Diarrhoea Research Program in Goroka, now vacant;
2. Research Fellow in Epidemilogy in the Tari Research Unit, Southern Highlands Province, investigating pneumonia, diarrhoea and nutrition, vacant in January 1985;
3. Research Fellow in Epidemiology in the Malaria Research Program in Madang, vacant in April 1985;
4. Research Fellow in Bacteriology in the Diarrhoea Research Program in Goroka, now vacant;
5. Research Fellow in Bacteriology in the Pneumonia Research Program in Goroka, vacant in October 1984;
6. Research Fellow in Virology in the Diarrhoea Research Program in Goroka, now vacant;
7. Research Fellow in Immunology in the Pneumonia Research Program in Goroka, now vacant; and
8. Research Fellow in Biostatistics, stationed in Goroka but responsible for statistical aspects of all research programs, now vacant.

Research Fellows are sought with a higher qualification in their respective field at PhD or MSc level, with suitable experience. Those with technical qualifications and relevant experience may apply. Salaries are in the range of K16,820 to K21,520 depending on qualifications and experience. Salaries are subject to CPI indexation. An additional allowance of K2000 is payable to those with clinical qualifications valid for medical registration in Papua New Guinea. One kina (K1.00) = U.S. $1.20. In addition to salary a gratuity of 24% of salary earned is payable each year (increasing to 32% after 3 years' service). Taxation on salary is at standard levels but the gratuity is taxed at a flat rate of 2%. Contracts are normally for three years, but may be given for two years, and are renewable. Economy air fares are paid for the employee and family between the place of residence and Papua New Guinea on recruitment and repatriation. In addition, return leave fares for the whole family are payable every eighteen months to place of residence. Free accommodation is provided in Papua New Guinea. Education expenses are paid in Papua New Guinea. For children attending high school overseas, education allowances are paid and a fare from school to Papua New Guinea payable twice a year. Settling-in and settling-out allowances are paid at the beginning and end of the contract period.

Applicants should send a full curriculum vitae, including details of qualifications and experience, and the names and addresses of three referees to

Dr Michael Alpers
Director
Papua New Guinea Institute of Medical Research
P.O. Box 60, Goroka, EHP
Papua New Guinea

by 31 July 1984.

STUDENTSHIPS

THE UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF BIOCHEMISTRY

SERC/CASE STUDENTSHIP

Applications are invited for a three year Ph.D. studentship starting October 1984 to work on the roles of lipid peroxidation and the covalent binding of drug metabolites in the development of liver toxicity.

The award is held cooperatively with Dr B Clark, Fisons Ltd., Pharmaceutical Division, Loughborough. Applicants must obtain a 1st or II(i) degree. Full curriculum vitae with names of two referees to Dr A A Horton, Department of Biochemistry, University of Birmingham, Birmingham B15 2TT. (2371)F

ROBERT GORDON'S INSTITUTE OF TECHNOLOGY

SCHOOL OF PHARMACY

RESEARCH STUDENTSHIPS IN PHARMACY AND PHARMACOLOGY

Applications are invited from graduates or students about to graduate with a 1st or 2nd Class Honours Degree in Pharmacy, Pharmacology, Biochemistry or Microbiology. Topics include

1. Mode of Action of DMSO

2. Characterisation of multiple-phase and oil-in-oil emulsions to evaluate their potential as vehicles for the controlled release of drugs

3. Mode of action of pharmaceutical preservatives on selected microbial species

4. The binding of anti-aggregatory compounds to , acid glycoprotein and to platelets

5. Involvement of products of arachidonic acid metabolism in platelet aggregation and bronchoconstriction.

Further details from Secretary, Robert Gordon's Institute of Technology, Schoolhill, Aberdeen AB9 1FR. (2895)F

OXFORD UNIVERSITY RESEARCH LABORATORY FOR ARCHAEOLOGY

Carbon-14 dating using a 2 MV tandem accelerator, thermoluminescence dating, archaeomagnetism: studentship(s) for DPhil research, suitable for physicists, chemists, earth scientists, anticipating a good honours degree.

ROTHAMSTED EXPERIMENTAL STATION Harpenden, Herts AL5 2JQ

PHYSIOLOGY & ENVIRONMENTAL PHYSICS DEPARTMENT

SERC CASE STUDENTSHIP: MATHEMATICAL MODELLING OF THE DRIFT OF AGRICULTURAL SPRAYS

Applications are invited for a SERC CASE Studentship tenable at Rothamsted Experimental Station and Imperial College of Science and Technology to study the drift of agricultural sprays downwind from crops. The project will involve field experiments and the use and adaptation of air pollution dispersion models.

Candidates should hold, or expect to obtain, a First or Upper Second Class Degree in Physics, Meteorology, Applied Mathematics or an Environmental Science.

Applications giving full cv and the names of two referees should be sent to: Dr H A McCartney, Physiology & Environmental Physics Department, Rothamsted Experimental Station, Harpenden, Herts AL5 2JQ by 1st June 1984 quoting Ref: 557.

We are equal opportunities employers. (2367)F

FACULTY OF SCIENCE

SERC RESEARCH STUDENTSHIPS IN BIOLOGICAL SCIENCES

(2 Posts)

Required to work in one of the following areas of research: Fish biotechnology/immunology; Plant biotechnology; Physiological adaptations of marine crustaceans; Treatment and control of parasitic diseases of fish

Candidates should hold or expect to gain this year a good Honours degree in Biological Sciences.

Further details and application forms may be obtained from:-Department of Biological Sciences, Plymouth Polytechnic, Drake Circus, Plymouth PL4 8AA. Tel: 0752 264659. (2877)F

Plymouth Polytechnic

UNIVERSITY OF READING

DEPARTMENT OF MICROBIOLOGY

AFRC CASE STUDENTSHIP

Applications are invited from graduates with a First or Upper Second Class Honours degree in Microbiology or a related subject or from those who expect to be awarded such a degree this year for a three year AFRC CASE studentship commencing in October 1984. The project, in collaboration with Cadbury Schweppes, will be to develop a method for the detection of small numbers of yeasts which cause spoilage of soft drinks, using monoclonal antibodies. The project will be supervised by Dr A I Tiffin (Reading) and Dr C S Gutteridge (Cadbury-Schweppes).

Further particulars may be obtained from Dr A I Tiffin, Department of Microbiology, University of Reading, London Road, Reading RG1 5AQ, to whom completed applications, a CV and the names of two academic referees should be submitted by 28 June, 1984. (2349)F

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF BIOCHEMISTRY

SGRC STUDENTSHIP IN STEROID BIOCHEMISTRY

Applications are invited for the above studentship, tenable for three years commencing October 1984. Candidates must hold, or expect to obtain, a I or II(i) Honours degree in an appropriate subject, and will be expected to register for a higher degree.

The project involves studying the relationship between sex steroids and the endometrium, particularly with respect to implantation, in cases of sub-fertility. The work will be carried out in the Department of Obstetrics and Gynaecology, but the student will also be a member of the Department of Biochemistry.

Applicants should write, giving names and addresses of two referees and enclosing a curriculum vitae to Dr P V Maynard, Department of Obstetrics and Gynaecology, University Hospital, Queen's Medical Centre, Nottingham NG7 2UH. (2325)F

UNIVERSITY OF ABERDEEN

INSTITUTE OF ENVIRONMENTAL AND OFFSHORE MEDICINE

POSTGRADUATE STUDENTSHIP

Applications are invited from suitably qualified graduates in physiology, pharmacology or related biological sciences for a postgraduate studentship in the Institute. The field of study will be hyperbaric pulmonary oxygen toxicity and the objective will be the determination of safe oxygen exposure limits in diverse. It is anticipated that research will involve both human volunteers and animal models.

The studentship is available at normal Research Council rates from 1 October 1984. Applications including CV and the names of two referees should reach Dr T Shields, Institute of Offshore and Environmental Medicine, Aberdeen, AB9 2ZD, as soon as possible but by 6 July at the latest. (2360)F

UNIVERSITY OF READING SERC-CASE STUDENTSHIP IN MICROBIOLOGY

Applications are invited for an SERC-CASE Studentship, in co-operation with ICI, tenable for 3 years from October 1984 in the Department of Microbiology. Applicants must have, or expect to receive this summer, a 1 or 2i honours degree in microbiology or a closely related subject and have a particular interest in the physiology and biochemistry of microorganisms. The successful applicant will investigate the effect of CO_2 on the growth and metabolism of methylotrophic bacteria growing on methanol (eg the organism used for single-cell protein by ICI) and will register for a higher degree. About 3 months will be spent at the ICI Research Laboratories during the 3 years. The value of the Studentship is £2,430 pa tax free (under review), plus University fees, plus £600 pa and some travel expenses from ICI.

Applications with full curriculum vitae including a telephone number and two academic referees should be sent before 29 June 1984 to Dr L J Zatman, Department of Microbiology, University of Reading, London Road, Reading RG1 5AQ. (2318)F

UNIVERSITY OF ABERDEEN

INSTITUTE OF ENVIRONMENTAL AND OFFSHORE MEDICINE

POSTGRADUATE STUDENTSHIP IN HUMAN PHYSIOLOGY

Applications are invited for a postgraduate studentship within the Institute. The project will investigate the role of substrate availability as a limiting factor in exercise performance, and will involve collection and analysis of blood and skeletal muscle samples from human volunteers. The effect of artificially induced variations in substrate availability on the metabolic response to exercise will be studied.

Applicants should have an interest in the physiology and biochemistry of exercise and should possess, or expect to obtain, a good honours degree in an appropriate discipline.

The Studentship is available at normal Research Council rates for a 3 year period from 1st October 1984. Applications including CV and the names of two referees, should reach Dr R Maughan, Institute of Offshore and Environmental Medicine, Foresterhill, AB9 2ZD, as soon as possible but by 6th July at the latest. (2361)F

STUDENTSHIPS *Continued*

THE UNIVERSITY OF OXFORD
Dyson Perrins Laboratory

SCIENCE AND ENGINEERING RESEARCH COUNCIL CASE STUDENTSHIP

Applications are invited for a CASE studentship leading to the degree of D Phil in organic chemistry to be held in the above department and sponsored by Shell Research Limited, Sittingbourne, Kent. The successful applicant will work with Dr L M Harwood on the isolation and synthesis of certain allelophathic agents from plant sources. Applicants should hold or expect to gain this year a good honours degree in chemistry and have a particular interest in organic synthesis.

It is intended that the studentship will be taken up by 1st October, 1984 and applications (including a curriculum vitae and quoting two referees) should be sent to Dr L M Harwood, the Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY. (2312)F

UNIVERSITY OF CAMBRIDGE

Applications are invited for

RESEARCH STUDENTSHIPS

for the PhD, one each in insect chemistry; nutrients of potatoes; establishment of wheat and two in soil processes.

Further details can be obtained from Professor Sir James Beament, Department of Applied Biology, Pembroke Street, Cambridge CB2 3DX. (2315)F

THE HATFIELD POLYTECHNIC

SCHOOL OF NATURAL SCIENCES

RESEARCH STUDENTSHIPS IN BIOLOGY

A SERC Studentship is available for one of the following projects:-

(i) cell-free transcription of exogenous plant DNA.

(ii) effects of morphological differentiation of Streptomyces spp. on antibiotic production.

(iii) identification of different races of Plasmodiophora brassicae.

A Research Assistantship is also available to work on the biotechnology of abattoir waste. This project will investigate microbiological and biochemical characteristics of abattoir waste and its potential for conversion into high value byproducts. Applicants for the post must possess a driving licence.

Applicants for both posts should possess a good honours degree in an appropriate subject and should submit a full Curriculum vitae and the names of two academic referees to Dr C Wilson, Biological Sciences, The Hatfield Polytechnic, P O Box 109, Hatfield, Herts. AL10 9AB (Hatfield 68100, Ext. 481). Full details of the projects are available on request.

Closing date: 9 July 1984 (2357)F

UNIVERSITY OF READING

NATIONAL COLLEGE OF FOOD TECHNOLOGY

AFRC STUDENTSHIP

Applications are invited from graduates who hold or expect to obtain first or upper second class honours degrees to work on either:

a) Glycosyl Transferases or

b) Physicochemical Aspects of Food Processing.

Candidates for project (a) should be graduates in biochemistry, microbiology, chemistry, food science or related subjects. Candidates for project (b) could also have degrees in engineering or applied physics.

Applications including a CV and names of two referees should be sent to Dr G G Birch, National College of Food Technology, Food Studies Building, University of Reading, Whiteknights, Reading, RG6 2AP. (2341)F

UNIVERSITY OF READING

DEPARTMENT OF PURE & APPLIED ZOOLOGY

Applications are invited for suitably qualified graduates for an

SERC STUDENTSHIP

to undertake research for a higher degree in the areas of comparative physiology, behaviour, parasitology or applied entomology.

Applicants should write to Professor K Simkiss, Department of Pure & Applied Zoology, Whiteknights, University of Reading, RG6 2AJ, stating their interests and enclosing a curriculum vitae with the names of 2 referees. (2316)F

WELSH NATIONAL SCHOOL OF MEDICINE
(University of Wales)

DEPARTMENT OF MEDICAL BIOCHEMISTRY

PHD STUDENTSHIP

Applications are invited for a Research Studentship (supported by the Welsh Scheme for the Development of Health and Social Research) tenable for three years commencing October 1984. The successful applicant will work under the supervision of Dr M A McPherson on biochemical control of exocrine secretion; with the aim of investigating abnormal regulatory factors(s) which may result from expression of the genetic defect in cystic fibrosis.

Candidates should have or expect to obtain a good Honours degree in Biochemistry or a closely-related subject.

Applicants should apply in writing, including a curriculum vitae with the names and addresses of two academic referees (quoting Ref No C38/4/50) to the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff, CF4 4XN (Tel No 0222/755944 Ext 2296) from whom further details are available. Closing date for application: 31st July, 1984. (2350)F

UNIVERSITY OF READING

DEPARTMENT OF AGRICULTURE AND HORTICULTURE

MAFF RESEARCH STUDENTSHIP

A MAFF research studentship is available from 1 October 1984 for a project on "The compensatory threshholds/tolerance limits of cereals to invasion by nematodes". The work will involve the use of growth regulators to alter the morphology of cereal roots and hence the potential invasion sites.

Applicants should send CV and the names of two referees to Dr N G M Hague, Department of Agriculture and Horticulture, Earley Gate, University of Reading, Whiteknights, Reading, RG6 2AT. (2342)F

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF ZOOLOGY

Research Studentships are available in at least two of the following fields: cell motility, the cytoskeleton of protozoans, cell surface receptors, insect parasitology, ecological genetics, avian ecology and the ultrastructure of lower vertebrates.

Further particulars are available from Dr D S O'Dell, Postgraduate Tutor, Department of Zoology, University College London, Gower Street, London WC1E 6BT (01-387 7050 Ext 424). Applications should include the names of two academic referees. (2887)F

UNIVERSITY OF READING

RESEARCH STUDENTSHIP IN MICROBIAL PHYSIOLOGY & BIOCHEMISTRY

Applications are invited for a Research Studentship tenable for 3 years from October 1984 in the Department of Microbiology. Applicants must have, or expect to receive this summer, a 1 or 2i honours degree in microbiology or a closely related subject and have a particular interest in the physiology and biochemistry of microorganisms. The successful applicant will register for a higher degree and will investigate the mechanism of nitrogen assimilation by microorganisms from natural habitats followed by physiological, biochemical and enzymological studies. Up to 64 hours per term demonstrating duties will be required for which extra payment will be made. The value of the Studentship is £2,430 pa tax-free (under review), plus approx £300 per term for demonstrating duties, plus University fees.

Applications with full curriculum vitae including a telephone number and two academic referees should be sent before 29 June 1984 to Dr L J Zatman, Department of Microbiology, University of Reading, London Road, Reading RG1 5AQ. (2317)F

UNIVERSITY OF ABERDEEN

DEPARTMENT OF OPHTHALMOLOGY

POSTGRADUATE STUDENTSHIP

Applications are invited from suitably qualified candidates for a 3-year postgraduate studentship to work on immunological aspects of ocular inflammatory disease, using an established model of experimental allergic uveo-retinitis (EAU). The work involves the use of purified retinal S antigen and is aimed at determining the relationship between altered immune responses to the antigen and severity of the disease.

The successful applicant will work in the new University Department of Ophthalmology and will be expected to participate in its development. Applicants should have a 1st or upper 2nd class Honours Degree in the biological sciences. Experience in biochemistry and/or immunology would be an advantage.

The Studentship will be at normal Research Council rates and is available immediately although it is expected to commence around October, 1984. Applications (together with with names of two referees) should be sent to Professor A Forrester, Department of Ophthalmology, University of Aberdeen, as soon as possible but by 6th July at the latest. (2362)F

UNIVERSITY OF LONDON
ST. GEORGE'S HOSPITAL MEDICAL SCHOOL

DEPARTMENT OF PHARMACOLOGY AND CLINICAL PHARMACOLOGY

SERC CASE AWARD STUDENTSHIP
In association with the Lilly Research Centre

Applications are invited from suitably qualified candidates (First or Upper Class Honours) for the above award tenable from October 1984.

The project, supervised by Professor J.S. Kelly and Dr S.R. Forda, involves the maintenance of 5HT containing neurones of the raphe nucleus in dissociated cell culture to provide a model in which the intrinsic activity of 5HT neurones can be examined. Electrophysiological, autoradiographic and immunocytochemical techniques will be used to identify the site and mechanism by which centrally active drugs of clinical importance, particularly antidepressants and analgesics, affect 5HT receptor function.

Applications, including brief curriculum vitae and the names of two referees should be sent to Professor J.S. Kelly, Department of Pharmacology and Clinical Pharmacology, St. George's Hospital Medical School, Cranmer Terrace, London SW17 0RE.

Further details can be obtained by writing to Professor Kelly or by telephoning (01-627 1255 Ext. 4722). (2889)F

ASSOCIATESHIPS

UNIVERSITY OF BIRMINGHAM

DEPARTMENTS OF BIOCHEMISTRY AND ZOOLOGY AND COMPARATIVE PHYSIOLOGY

RESEARCH ASSOCIATESHIP

Applications are invited for the above post to work on the isolation and characterisation of naturally occurring factors which inhibit growth and oviposition in freshwater snail hosts of schistosome parasites.

It is anticipated that the successful candidate will hold at least an upper second class honours degree in Biochemistry or a related subject, and it would be possible to register for a higher degree.

The post is initially for one year but support for a further two years is envisaged, subject to satisfactory progress.

Salary on the Research Associate 1B scale £6,310 — £8,530 plus superannuation.

For further particulars phone 021-472 1301 ext 2559, quoting reference J3.

No formal application form. Three copies of application, including full Curriculum Vitae and naming three referees to Assistant Registrar, (Science and Engineering), PO Box 363, Birmingham B15 2TT by June 1984. (2320)O

ACCOMMODATION

SOUTH SUBURB Paris, furnished apartment for academic visitor — Aug 84 — Sept 85. Three bed rooms. Equipped kitchen — convenient for Paris, Orsay, Saclay. Meudon, Créteil, Villejuif. Dr Pierre Gibart, Le Hameau de Pré du Lac, F-06740 Chateau Neuf de Grasse (W1053)S

FELLOWSHIPS

UNIVERSITY OF EAST ANGLIA
Norwich

Applications are invited for a University Postdoctoral Fellowship in

ACID RAIN RESEARCH

The person appointed will work on *either*: a) Soil Microbiology — Acid Rain Interactions *or* b) Factors Controlling the pH of Rain in Remote Areas. Project a) requires someone with experience in soil microbiology, and project b) needs a person trained in chemistry and/or environmental chemistry. The appointment is for two years starting 1 October 1984, or as soon as possible thereafter. Salary on the scale £7,190 — £8,530 per annum plus USS (under review).

Further information is available from Dr T.D. Davies (project a)) or Dr P.S. Liss (project b)), School of Environmental Sciences, University of East Anglia, Norwich NR4 7TJ. Applications, including the names of two referees, should be sent as soon as possible to the Dean of the School of Environmental Sciences, University of East Anglia, Norwich NR4 7TJ. (2873)E

NIHE

NATIONAL INSTITUTE FOR HIGHER EDUCATION DUBLIN

POSTDOCTORAL FELLOWSHIP: GROWTH FACTORS IN CELL CULTURE

A fellowship exists, supported by the Irish Cancer Society, to work on genetic control of growth factor production by human tumour cells in culture. Experience in cell culture, recombinant DNA techniques or peptide separations would be an advantage. Applications to: Dr. M. Clynes, School of Biological Sciences, N.I.H.E., Glasnevin, Dublin 9, Ireland. (2876)E

UNIVERSITY OF EDINBURGH

DEPARTMENT OF ZOOLOGY

POST-DOCTORAL FELLOWSHIP IN BIOCHEMISTRY

Applications are invited for a SERC Fellowship to work on the biochemistry of the yeast cell cycle. Research range IA starting 1 October 1984.

Further particulars are available from Professor J M Mitchison, Department of Zoology, University of Edinburgh, Kings Buildings, West Mains Road, Edinburgh EH9 3JT with whom applications (2 copies) including CV and the names of two referees should be lodged not later than 9 July 1984.

Please quote reference No 5178. (2311)E

THE HATFIELD POLYTECHNIC

SCHOOL OF NATURAL SCIENCES

POST-DOCTORAL FELLOWSHIP IN BIOTECHNOLOGY

Applications are invited for a Post-Doctoral Fellowship to work on either:-

(i) the stability of plasmid vectors in yeast; or,

(ii) the molecular biology of algal viruses.

Both projects require expertise in recombinant DNA techniques. Experience in either yeast research or continuous culture would be an asset for the plasmid vector project and experience in animal or plant virus for the algal viruses project.

Full details of both projects may be obtained from Dr E GINGOLD, Biological Sciences, The Hatfield Polytechnic, P O Box 109, Hatfield, Herts. AL10 9AB (Hatfield 68100, Ext.489).

The appointment is for three years from October 1984. The salary is in the range of £7,215 - £9,801 + £258 Local Allowance (under review).

Applicants, who should possess a PhD or have submitted a thesis, should submit a full Curriculum vitae and the names of two academic referees to Dr Gingold.

Closing date for applications: 16 July 1984 (2356)E

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF MICROBIOLOGY

RESEARCH FELLOWSHIP

Applications invited for this MRC funded post. The Project is designed to purify and characterise enterotoxin(s) of Salmonella typhimurium as a prelude to detecting their production, location and release in vivo by immunoelectron microscopy. Work will be carried out in Departments of Microbiology and Institute of Child Health in conjunction with Department of Physiology of Birmingham University.

The post is tenable for up to three years from the soonest possible date.

Salary on the Research Fellow 1A scale £7,190-£11,615 plus superannuation.

For further particulars phone 021-472 1301 ext 2559, quoting reference M5.

No formal application form. Three copies of application, including full Curriculum Vitae and naming three referees to Assistant Registrar, (Science and Engineering), PO Box 363, Birmingham B15 2TT by 29 June, 1984. (2880)E

THE UNIVERSITY OF SYDNEY

ROTHMANS FELLOWSHIPS

Applications are invited for Rothmans Fellowships, which are awarded under the Rothmans University Endowment Fund set up by Rothmans of Pall Mall (Australia) Limited to enable Fellows to undertake postgraduate work within an Australian University.

Rothmans Fellowships are of an annual value of up to $A17,000. A Fellow may be paid travelling expenses incurred in taking up the Fellowship and returning home.

In addition, an amount of $A2,000 pa towards fees and expenses including the purchase and maintenance of equipment may be paid to the University where the Fellow is working.

A Fellow shall take up a Fellowship before attaining the age of twenty-eight. The Fellowships are open to graduates of any University who have had at least three years postgraduate experience in research. The Fellowships are not open to permanent members of academic staff or applicants proceeding on sabbatical, study or other leave (including leave without pay). The Fellowships must be held at an Australian University.

Application forms and further details may be obtained from The Secretary, Rothmans University Endowment Fund, c/o The University of Sydney, NSW 2006, Australia, or from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications close on 29 July 1984. (W1060)E

UNIVERSITY OF BIRMINGHAM

DEPARTMENTS OF MICROBIOLOGY AND GENETICS

POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited for the above post which is funded by an MRC grant to Dr C W Penn (Microbiology) and Dr C M Thomas (Genetics). The work will involve cloning and expression of antigen genes of the syphilis agent Treponema pallidum in Escherichia coli. Candidates should have a background in microbiology and/or biochemistry and should preferably have some experience of recombinant DNA techniques, although this is not essential.

Post tenable for up to three years from 1/4/84 or as soon as possible thereafter.

Salary on the Research Fellow 1A scale £7,190-£11,615 plus superannuation.

For further particulars phone 021-472 1301 ext 2559, quoting reference M6.

No formal application form. Three copies of application, including full Curriculum Vitae and naming three referees to Assistant Registrar, (Science and Engineering), PO Box 363, Birmingham B15 2TT by 29 June 1984. (2879)E

UNIVERSITY OF WAIKATO

POST-DOCTORAL FELLOWSHIPS

(A 84/15)

The University of Waikato invites applications for post-doctoral fellowships to be taken up during 1985 for one or for three years. The fellowships will be funded and awarded by the University Grants Committee and tenable at the University of Waikato.

Applications from candidates who wish to hold a fellowship in any department of the University will be considered: the University Grants Committee, however, in making the awards, will give priority to current growth research areas such as biotechnology, genetic engineering, electronics, engineering, chemistry, etc.

Applicants should have been awarded, or qualified for the award of, the degree of Doctor of Philosophy.

The emolument payable to the Fellow will be determined at a rate not exceeding step one of the scale for Lecturers (ie NZ$21,660 p.a.).

Before lodging an application, prospective applicants should obtain details of the method of application and conditions of appointment from the Registrar, University of Waikato, Private Bag, Hamilton, New Zealand, or from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF. Applications should be forwarded to the Registrar by 25 June 1984. (W1055)E

FELLOWSHIPS *continued*

Southampton THE UNIVERSITY

INSTITUTE OF CRYOGENICS RESEARCH FELLOWSHIP

Applications are invited for a 2 year research fellowship supported by SERC to study convection in cryogenic fluids using Laser Doppler Anemometry and microthermometry. Experience with data processing and lasers preferred.

Salary on range: £7,190-£8,080 per annum (under review).

Applications giving Curriculum Vitae (in duplicate) and names of two referees should be sent to D.A.S. Copland, Southampton University, Highfield, Southampton, SO9 5NH as soon as possible quoting reference 2056. (2340)E

Special Training Fellowships in Recombinant DNA Technology

Applications are invited for fellowships for any period from 6 months to three years commencing on or after 1 May 1985 from scientists requiring training in recombinant DNA techniques. Applicants may be young postdoctoral scientists (or those just completing PhD's) or more mature scientists with established reputations in other areas wishing to enter this field. Permanent academic staff with unpaid leave of absence may apply.

These fellowships are tenable in any UK institution offering training appropriate to the applicant's needs. UK residents currently working abroad may apply.

MRC Medical Research Council

Application forms, and further details may be obtained from Training Awards Group, Medical Research Council, 20 Park Crescent, London W1N 4AL. (Tel: 01-636 5422 Ext 448)

Closing date: 15 October 1984

(2896)E

THE RANK PRIZE FUNDS

Rank/Widdowson Post-Doctoral Fellowship in Child Nutrition

The Trustees of The Rank Prize Funds are to honour Dr. Elsie Widdowson, F.R.S. by establishing for three years a Post-Doctoral Fellowship at the M.R.C. Dunn Nutrition Unit to work on the metabolic and physiological aspects of infant nutrition.

Applicants should have a recently awarded Ph.D. in an appropriate biological science or expect to be awarded a Doctorate in the near future.

Details will be provided to short listed candidates.

Applicants should write to Dr. R. G. Whitehead, M.R.C. Dunn Nutrition Unit, Downhams Lane, Milton Road, Cambridge, CB4 1XJ giving details of their previous research experience and indicating the type of work which they would like to pursue in the field of infant nutrition.

The terms and conditions of service for this Fellowship will be identical with those of an M.R.C. Post-Doctoral Fellowship.

Applications should reach the Dunn Nutrition Unit by the 15th July, 1984. (2343)E

E M B O
European Molecular Biology Organization
LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY
AUTUMN 1984 AWARDS
Next deadline: August 15, 1984

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligibile a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country. Long term fellowships are awarded initially for one year, but depending on a review of progress, they be renewed for a second year. In cases of exceptional scientific merit renewal for a third year is possible. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is August 15, 1984. Successful candidates will be notified of their awards immediately after the meeting of the selection committee, which is on October 29, 1984.

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F.R. Germany.

(W1016)E

ICI

NEW SCIENCE GROUP
POSTDOCTORAL RESEARCH FELLOWSHIP AT MIT

Applications are invited from suitably qualified candidates for an ICI New Science Group Postdoctoral Fellowship based within the Department of Materials Science at the Massachusetts Institute of Technology in Boston, USA. This prestigious appointment will be for two years with a starting date in September 1984. The research fellow will be involved in studies of sintering phenomena in ceramic precursor systems and will work in close association with Professor J.D. Birchall FRS at ICI's New Science Group in his capacity as Visiting Professor at MIT.

The fellowship offers a unique opportunity for carrying out original research with leading edge University and Industrial research laboratories. Applications are invited from candidates with a PhD in Physical or Inorganic Chemistry, Materials Science, Solid State Physics or Ceramics who feel that they could contribute to the aims of this fundamental research programme.

The value of the Fellowship is $23,000 per annum with travelling expenses to and from the UK at the start and finish of the fellowship being provided by ICI. It is anticipated that the Fellowship may well lead to employment with ICI New Science Group on completion.

Applicants should send a curriculum vitae and the names of three referees to Miss E. Lauermann, Personnel Officer, Imperial Chemical Industries PLC, New Science Group, P.O. Box 11, The Heath, Runcorn, Cheshire, marking the envelope MIT Fellowship. The closing date for applications is 28th June 1984.

GRANTS and SCHOLARSHIPS

Rainbow Research Scholarship

Bass Public Limited Company invite applications for the Rainbow Research Scholarship, which was founded in memory of the contribution to brewing science by the late Dr. C. Rainbow and which falls vacant in January 1985 for the second occasion. Candidates should hold a first or second class honours degree, preferably in genetics or a related subject.

The project entitled "Developing Systems for Genetic Manipulation of Brewing Yeast", is aimed at the generation of new vector systems for yeast and rendering *Saccharomyces* spp. more amenable to genetic manipulation. The successful candidate will be required to seek registration with the Council for National Academic Awards for the degree of Doctor of Philosophy and will spend a period of 3 years in the research laboratories at Burton-on-Trent, where working conditions and facilities are first-class. This constitutes a unique opportunity to acquire research training in a progressive industrial research environment.

We will meet all the costs of the project and associated fees. The candidate will have access to the comprehensive sporting and social facilities provided by the Company. Written application, curriculum vitae and the names of two referees should be addressed to:-

Director of Research,
Bass Public Limited Company,
137 High Street, Burton-on-Trent, DE14 1JZ.

Bass
Public Limited Company

AWARDS

British Diabetic Association/ St Bartholomew's Hospital

ANDREW CUDWORTH MEMORIAL PRIZE

To commemorate the work of the late Professor Andrew Cudworth, the British Diabetic Association, jointly with the Department of Medicine, St Bartholomew's Hospital, offers a prize of £250 for the best essay submitted on any aspect of diabetes mellitus. Essays should not exceed 10,000 words and the winner may be invited to present the work to one of the meetings of the Medical and Scientific Section for publication.

Applicants should be under age 40 and of British nationality. Four copies of the essay should be submitted for consideration to the Secretary General, British Diabetic Association, 10 Queen Anne Street, London, W1M OBD by 30th September 1984. **(2892)N**

ASSISTANTSHIPS

UNIVERSITY OF SOUTHAMPTON
FACULTY OF MATHEMATICAL STUDIES
RESEARCH ASSISTANTSHIP IN SEMI CONDUCTOR MODELLING

Applications are invited from candidates with a good degree for a Research Assistantship, tenable from September 1984. Theoretical studies will be carried out on the Physics of Polycrystalline silicon devices in parallel with experimental work in the electronics department and in industry. The successful applicant may be permitted to register part-time for a higher degree.

Salary according to qualifications on scale up to £8080 per annum.

Applications giving a telephone number should be sent by 2nd July 1984 to Professor P T Landsberg, The University, Southampton SO9 5NH. Applicants are requested to ask two referees to write on their behalf at the same time. (2374)P

UNIVERSITY OF STIRLING
DEPARTMENT OF BIOLOGICAL SCIENCE

Applications are invited for two research assistantships, each for up to two years, to set up the first phase of a study of the dynamics of primary rain forest in Sabah, Malaysia. The research is funded by an NERC grant awarded to Dr D M Newbery. One post is for a plant ecologist and the other for a plant taxonomist.

Applicants should be graduates in botany or a related subject, preferably with some postgraduate experience in tropical botany or forestry and ideally not older than 26 years of age. The appointees are expected to spend about two-thirds of their time in the field. The starting date is 1 January 1985.

Further particulars from, and applications (naming two referees) to: The University Secretary, University of Stirling, Stirling FK9 4LA. Tel: 73171, ext 2314. Closing date: 16 July 1984. (2346)P

THE POLYTECHNIC OF NORTH LONDON
SCHOOL OF APPLIED PHYSICS
TWO ONE-YEAR RESEARCH ASSISTANTSHIPS

are required for: 1 Study of excitation processes in electrical discharges in low pressure gases, relevant to improving sources for applied spectroscopy. Co-operation with the Institut für Spektrochemie, Dortmund, is planned; extension of tenure for the post, and registration for a higher degree, may be possible. 2 Study of 1/f noise, by the use of an autocorrelation method, at very low frequencies. The work will involve interfacing a microprocessor to various sources of electronic noise.

The salary for these posts, the duties of which include six hours' teaching per week, is £4,946 + £987 London Allowance.

Candidates should have good Honours degrees in physics, or equivalent, and should apply direct to the Head of the School of Applied Physics, Polytechnic of North London, Holloway Road, London N7 8DB, (Tel: 01-607 2789), stating the post in which interested and with brief details of qualifications and experience. (2309)P

CONFERENCES and COURSES

M.Sc. in Analytical Chemistry

This postgraduate course, involving lecture courses, extensive practical work with modern analytical instrumentation, and preparation of a dissertation on a research topic, can be completed over a period of six academic terms by full-time candidates, and in not less than 24 months by part-time candidates. Candidates having or expecting to have at least a Second Class Honours Degree in Science, with substantial Chemistry content, are eligible to apply and are invited to attend an Open Day in the Analytical laboratories in mid-July or early September.
The closing date for receipt of applications is Saturday, 15 September, but candidates wishing to be considered for financial support as post-graduate demonstrators should apply not later than Friday, 20 July.
Application forms and further information may be obtained from Professor J. Cunningham, Head of the Department of Chemistry (Telephone (021) 26871, ext 2374) (2358)C

NOW DO COMPUTING COLORIMETRY WITH YOUR ISCO UA-5 DETECTOR

No more manual calculation of each concentration — this new accessory for your UA-5 absorbance detector will do it for you.

The microprocessor-controlled Concentration Readout saves time and improves your accuracy. It converts sample absorbance to concentration, then displays and prints it directly in any units you choose: mg/ml, g%, mol/ℓ, lb/gal . . . whatever. Use it with the UA-5 to automate such UV-VIS colorimetric assays as enzymes at 340 or 365 nm,

proteins or nucleic acids at 214 or 254 nm, or heme proteins at 405 nm.

You can use the Concentration Readout to read solutions in spectrophotometer-type cuvets; in a semi-automatic sipper system using the WIZ smartpump/dispenser to carry samples through a UA-5 flow cell; and in a fully automated system with the ISIS AutoSampler, WIZ and printer. In the automated system, you can print sample number and concentration of up to 114 samples without operator intervention.

The Concentration Readout is our latest accessory to keep the UA-5 ahead of other detectors you could buy. A UA-5 has 18 available wavelengths from 214 to 660 nm and full-scale sensitivity ranges from 0.002 A to 2.0 A. You can choose from 14 flow cells for applications ranging from μLC (0.12 μl volume!) and HPLC to large-scale prep work. Use it to scan electrophoresed gels or centrifuged density gradients, monitor simultaneously two separate columns or one column at two wavelengths, and, of course, to read solution absorbance in lift-out cuvets. And now, with the Concentration Readout, the UA-5 gives you those readings automatically and directly in the units you want.

For more information about the UA-5 lab system, write ISCO, P.O. Box 5347, Lincoln, Nebraska 68505, U.S.A.

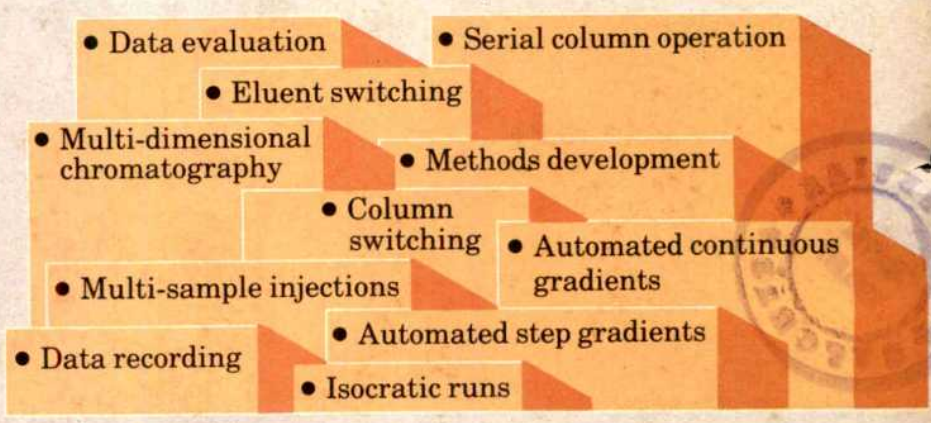
When you say "why FPLC" you are half way there ...

... because FPLC instrumentation from Pharmacia is the state of the art in high performance chromatography equipment for the separation of biologically active molecules.



Unlike any other chromatography system, the FPLC System was designed from the beginning to meet the demands for high performance separations of complex biomolecules. Since all wetted surfaces are of glass, titanium and fluoroplastics, aqueous buffer solutions and organic solvents may be used for separating biological molecules while maintaining biological activity.

The Pharmacia FPLC System is modular and can be tailored to your needs and budget. Depending on the exact configuration chosen, the FPLC System will provide you with any of the following techniques using both the new high performance columns and traditional chromatographic procedures.

... so go all the way.

With the Pharmacia FPLC System separations of biomolecules are easily performed. Chromatography can be fully automated and reproducible results will be obtained while operator time is kept to a minimum.

FPLC from Pharmacia goes beyond HPLC with biocompatibility

NEW ACRYLAMIDE REAGENT WITH UNBEATABLE PURITY

The proof is in the FREE sample. Send for it today & test it tomorrow.

Minimum assay (ex N) 99.9%
$E^{1\%}_{1cm}$ at 290 nm (aqueous) not more than 0.10
Maximum level of impurities are 0.001% for both acrylic acid (conductometric) and water insoluble matter – one fifth the content of competing material.

Product Code Ordering Nos: 100 gm 44313 2V 500 gm 44313 4A

Fill in the coupon for details of the complete range of Electran electrophoresis reagents, including the new Acrylamide Grade 1.

Circle No.18 on Reader Service Card.

Recent developments in molecular biology, many of which have been described by their authors in *Nature*, are helping to clarify the causes of cancer. With each passing week, more and more people consider that a full understanding of cancer cannot be long delayed. But the implications for physicians and their patients are still entirely unclear.

Organized and presented by NATURE, the international journal of science

Perhaps the most important international conference you could attend in 1984. Devoted to the recent contributions of molecular biology to the understanding of malignant disease.

For Research Scientists and Clinicians

IN SEARCH OF UNDERSTANDING...

THE MOLECULAR BIOLOGY OF CANCER

This is why NATURE has chosen to devote its third international conference to an occasion when researchers in the life sciences and clinicians can assess the importance of recent developments in molecular biology for the understanding and ultimately for the treatment of cancer.

SEPTEMBER 10, 11, 12, 1984
BOSTON PARK PLAZA HOTEL

Park Plaza at Arlington Street
Boston, MA 02117 U.S.A.

The conference program has been designed for two groups of people—researchers in the life sciences anxious to learn about and discuss the latest developments in the molecular biology of cancer, and physicians who consider that these developments may eventually affect their own work with patients.

Participation in the conference will be restricted so as to provide opportunities for those participating to mix with and to question those responsible for the latest research.

To this end, the leading scientists making formal presentations will also take part in two-hour round table discussions, providing an ample and unusual opportunity for participants to take part in detailed discussions and to make short presentations of their own.

To take part in this important and novel conference, register now and book your rooms (also limited) at the Boston Park Plaza Hotel and Towers.

TO REGISTER FOR THE CONFERENCE: Return the form appearing in this advertisement, with your check, or an authorized purchase order from your organization.

EARLY REGISTRANTS SAVE $50: If your registration and payment is received by July 1, you may deduct $50 from the regular full registration fee of $325. You pay only $275.

THE SETTING: Boston Park Plaza Hotel and Towers, Boston located at Park Plaza and Arlington Street, just off the famous Boston Public Gardens and Common.

ROOM RESERVATIONS: A large block of rooms has been set aside for attendees, but we do suggest that you reserve your accommodations early, to avoid disappointment. Rooms must be reserved directly with the Hotel, at (617) 426-2000, or 800-225-2008, Telex: 710 321 1088. Be certain to mention your participation in the "Nature Conference", to take advantage of these special lower rates: Singles: $70, 80 & 85; Double: $85, 95 & 100.

CONFERENCE DINNER: The Conference dinner will be held on Tuesday evening, September 11th, in the Imperial Ballroom. TO INSURE SEATING AT THE CONFERENCE DINNER, please include your dinner ticket requirements and payment of $25 per person with your Registration.

POSTER SESSIONS: A limited space for posters will be made available. Please write to: Poster Sessions Editor, Nature Publishing Company, 15 E 26 St., N.Y., NY 10010.

RECRUITMENT CENTER: Private meeting rooms and staff will be provided for recruitment executives and scientists to discuss employment opportunities. Contact: Miss Gene Fein, Recruitment Services Manager, Nature Publishing Co., 15 E. 26 St., N.Y., NY 10010, (212) 689-5900.

THE MOLECULAR BIOLOGY OF

CANCER

Conference Program
September 10-12, 1984
Boston Park Plaza Hotel

Daily Themes:

DAY 1 - ONCOGENES,
DAY 2 - THE CANCER CELL,
DAY 3 - PROSPECTS/PROBLEMS.

DAY 1

MONDAY, 10 September
Exhibition Viewing: 8:30am— 6:30pm
Recruitment Center: 9:30am— 6:00pm

ONCOGENES AND GROWTH FACTORS — WHAT THEY ARE AND WHAT THEY DO

9:00— 9:15	Chairman
9:15—10:00	Oncogenes *R. Weinberg (MIT)*
10:00—10:45	Growth factors *M. Sporn (NIH)*
11:15—12:00	HTLV *R. Gallo (NIH)*
12:00—12:30	Clinician's View *S. Broder (NIH)*
2:00— 4:00	Roundtables with morning speakers
4:30— 5:30	The Cancer Cell *J. Cairns (Harvard)*

DAY 2

TUESDAY, 11 September
Exhibition Viewing: 8:30am— 6:30pm
Recruitment Center: 8:30am— 6:00pm

THE CANCER CELL — HEREDITARY CANCER, TUMOR PROMOTERS AND CARCINOGENESIS

9:00— 9:15	Chairman
9:15—10:00	Gene Regulation *P. Leder (Harvard)*
10:00—10:45	Hereditary cancer *R. White (Utah)*
11:15—12:00	Carcinogens and promoters *I.B. Weinstein (Columbia)*
12:00—12:30	Clinician's View *F. Gilbert (Mt. Sinai)*
2:00— 4:00	Roundtables with morning speakers
4:30— 5:30	NCI program

DAY 3

WEDNESDAY, 12 September
Exhibition Viewing: 8:30am— 3:00pm
Recruitment Center: 8:30am— 3:00pm

PROSPECTS AND PROBLEMS— DRUG RESISTANCE, MONOCLONAL ANTIBODIES AND NEW DRUGS

9:00— 9:15	Chairman
9:15—10:00	Diagnostics and therapeutics *G. Todaro (Oncogen)*
10:00—10:45	Immunotoxins *J. Uhr (Texas)*
11:15—12:00	Drug resistance *A. Varshavsky (MIT)*
12:00—12:30	Clinician's View *J. Gutterman (Houston)*
2:00— 4:00	Roundtables with morning speakers
4:00— 4:45	Prospects
4:45	Closing remarks

TO REGISTER FOR THE CONFERENCE, mail this form with your payment.

Please reserve my place at

The Molecular Biology of CANCER

I wish to reserve _____ Conference Registration(s) in the names of: *(Please print or type)*

_____

and _____ Seats at the Tuesday Evening Dinner in the names of:

_____

Name _____ Title _____

Co./Institution _____

Address _____

City, State, Zip _____

I understand that as a paid conference participant, I may attend all sessions, and receive all programs and other materials.

My Check for $_____ is enclosed.
Charge My Credit Card as Shown:
☐ AMEX ☐ VISA ☐ MASTERCARD
Credit Card # _____ Expiration date _____

Signature _____
(as it appears on credit card)
☐ Please Bill Me
☐ Please Bill My Organization

RETURN TO:

Sensitive It Is. Radioactive It Isn't.

The DNA Detection System From BRL.

Until now, only a radioactive label could provide the sensitivity required for detecting small quantities of DNA. Today—with BRL's new DNA Detection System—*you can visualize even single copy genes without radioactivity.*

What the DNA Detection System is:

Sensitive. Using this enzyme-based system, together with the nonradioactive label biotin-11-dUTP, *you can detect 2 to 5 picograms of DNA.* The key to this extraordinary ability is a polymer of alkaline phosphatase, which provides far greater sensitivity than horseradish peroxidase.

Reliable. *Only BRL provides pretested reagents for making DNA test strips* on your nitrocellulose. Developed beside your filter, test strips act as an internal control, enabling you to monitor each visualization reaction.

Easy to use. All the reagents in the system—biotinylated poly alkaline phosphatase, streptavidin, dyes, biotinylated control DNA and DNA dilution buffer—are prescreened for use together. They are packaged in a convenient plastic container in which the filter can be developed. In addition, BRL's DNA detection experts have compiled a clear, step-by-step instruction manual which is included with the system. Our scientists also can assist you when you call the BRL Tech-Line™.

Flexible. You can label your DNA with biotin-11-dUTP and the nick translation reagents or labeling protocol of your choice. Of course, if you choose to purchase BRL's own Nick Translation Reagent System and our Biotin-11-dUTP, you can be assured of optimal results, because they are completely qualified for use with our companion DNA Detection System.

Rapid and inexpensive. Faster than autoradiography, the DNA Detection System actually costs less to use and requires no expensive equipment.

What the DNA Detection System Isn't:

Radioactive. Used with biotin-11-dUTP, our system has none of the safety, stability and disposal problems associated with radiolabeling for autoradiography.

Ask for our brochure and try BRL's DNA Detection System. You'll like it for what it is—and for what it isn't.

SCIENCE IN THE LOW COUNTRIES

- *Will the policy of "concentrating" the universities in Holland and Belgium create more problems than it solves?*
- *Is Belgian science stagnating?*
- *What would be the effect of increased government control over Dutch research policy?*

These and other questions are examined in *Nature*'s special supplement on Science in the Low Countries.
Extra copies of this issue are available now from the address given below.

- Dorothy Nelkin reviews David Dickson's *The New Politics of Science*

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

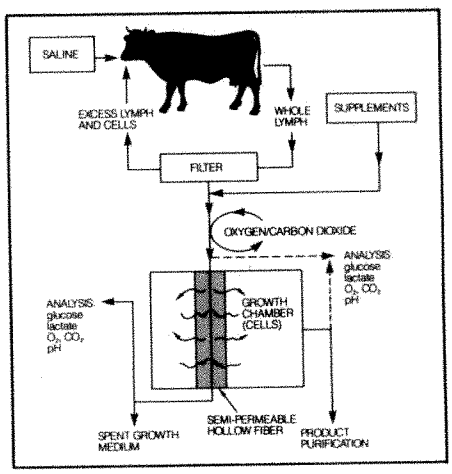
Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.



References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

NATURE'S BIOREACTOR

The New Bio-Response MCT* (Mass Culturing Technique) System Delivers Monoclonal Antibodies And Other Mammalian Cell Products When You Need Them—From Grams To Kilograms.

Insufficient quantities of desired peptides are a key cause of expensive research and production delays. The MCT system is a *new* and *unique* mammalian cell culturing process designed to overcome the obstacle of insufficient quantities of peptides by delivering the quantity you need...*when you need it!* Additionally, every step in MCT production has been developed to contain costs now and in the future while maintaining exceptional purity and quality in mammalian cell proteins.

Quantity

Unlike conventional cell-culture methods, the MCT system uses "fresh," free-flowing lymph directly from a cow. Following treatment, the lymph is continuously diffused into and out of a growth chamber. This nearly *in vivo* growth environment stimulates continuous and optimal protein secretion. The result? Large quantities of desired proteins enabling you to move to the clinic or market...*faster.*

Cost

Unlike conventional cell-culture methods that require extensive labor forces and expensive growth mediums, Bio-Response's MCT is a closed, steady-state system. In essence, the MCT system starts with a low-cost lifeline—a feeding cow—and ends with a pure, quality product. MCT ...*an optimal system at low cost.*

Purity

Unlike conventional cell-culture methods, the MCT system is designed to insure purity without tedious processing. By directing the lymph across semi-permeable membranes, MCT provides both separation of media protein from desired cell products, and a continuous nutrient flow. The ability to add or withdraw from the chamber to maintain optimal cell density permits continuous harvest of a highly pure product.

Quality

Unlike conventional methods of production that attempt to create biologically active mammalian cell products, the MCT system provides a pure-mammalian product—an exact copy of the original protein and, in the case of non-antibody polypeptides, uncompromised by inappropriate glycosylation and disulfide bond formation. There is a growing consensus favoring products produced in a mammalian cell-culture system, such as the Bio-Response MCT system.

Isolate DNA and RNA with CsTFA™ a new centrifugation medium

- Convenient isolation of nucleic acids
- Improves purity and quality
- Bands all types of RNA
- Inhibits nuclease activity
- Fewer phenol extractions
- Easy recovery by ethanol precipitation
- EtBr-free one-step plasmid isolation

Contact us today for more information on CsTFA and other high quality centrifugation media for nucleic acids, including optical and reagent grades of CsCl, or order directly from your local representative.

BACHEM ... a good name for biologically active peptides.

With its listing of nearly more than 4 000 chemical compounds in the field of **biologically active peptides**, including protected amino acid derivatives and peptide fragments for various methods of peptide synthesis, **BACHEM's new catalog S7 1984/85** is one of the most important tools for all those scientists requiring the most different biologically active peptides for their daily laboratory work. If you did not receive the catalog till now, please, send for your free copy. Nevertheless, if you cannot find a particular peptide in our catalog S7, please do not hesitate to contact our specialists for **custom syntheses** and you will get a prompt quotation.

Are you looking, however, for somebody able to produce large quantities of biologically active peptides or to help you in the transformation of theoretical synthetic considerations into the sometimes cumbersome practice of peptide synthesis, we present us as your partner for **contract work.**
Finally, the following information sheets are now available in new editions:

- BA 035 Substance P, Analogs and Sequence of Substance P, Antagonists of Substance P.
- BA 040 Enkephalins, Endorphins and Opioid Peptides.
- BA 013 Enzyme Substrates.
- BA 003 FMOC-amino Acids.

All peptides described in these information sheets have been synthesized by our peptide synthesis department following the best synthetic ways either by conventional or by solid-phase methods.
Solid-phase chemistry at BACHEM's laboratories is now exclusively performed on the new **LABORTEC Peptide Synthesizer SP 640,** an instrument which convinces by its ease of handling, its high reliability and, especially, by its very low price. You should immediately ask LABORTEC for more information and prices on its Peptide Synthesizer SP 640.

Let the NEN advantage in molecular biology work for you.

The NEN advantage is the superior performance you get from products at the forefront of biotechnology. In molecular biology especially we offer a variety of innovative products in response to your specific needs. Here are three examples.

Pretested research systems—
We offer three new systems: C-Tailing and Cloning, Southern Cross/Restriction Mapping, and Wheat Germ Translation. That makes 16 systems pioneered by NEN to bring convenience and reproducibility to molecular biology studies.

Autoradiography Enhancers—
We continue to lead the industry with EN^{3}HANCE™ and ENLIGHTNING™, the enhancers that drastically reduce processing time.

^{35}S-Nucleotides
Perhaps the best example of our commitment to biotechnology is our ^{35}S-nucleotides, pioneered by NEN as a superior alternative to the conventional use of ^{32}P. The technical and safety advantages of using ^{35}S are widely recognized, and we are collaborating with the research community to develop further applications.

Let the NEN advantage work for you. Ask your NEN Technical Representative to give you more information about these and our other problem-solving products for molecular biology.

From the innovators in electro-blotting, a powerful new high performance system.

Bio-Rad's new electro-blot system offers unprecedented power, resolution, and simplicity of operation. The key performers in the new system are the Trans-Blot® Cell and Model 250/2.5 Power Supply. Together, they provide a level of performance previously unobtainable.

New Trans-Blot Cell

- Accommodates 3 gel cassettes with convenient handles for easy removal. A unique gel cassette clamping system eliminates slippage, and provides positive contact between membrane and gel.
- One-piece molded construction prevents leaking and increases strength, assuring many years of use.
- Removable platinum electrode cards designed for easy cleaning.
- High efficiency cooling coil.

New 250-Volt, 2.5 Amp Power Supply

- Constant voltage, continuously adjustable from 0-250 volts. 0-2.5 amps.

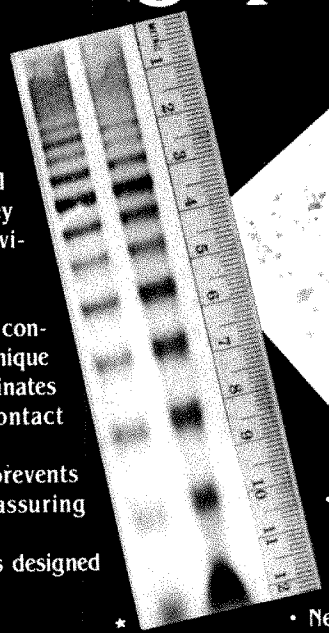

*Photo courtesy of William Garrard and David Gross, University of Texas Health Science Center, Dallas TX.

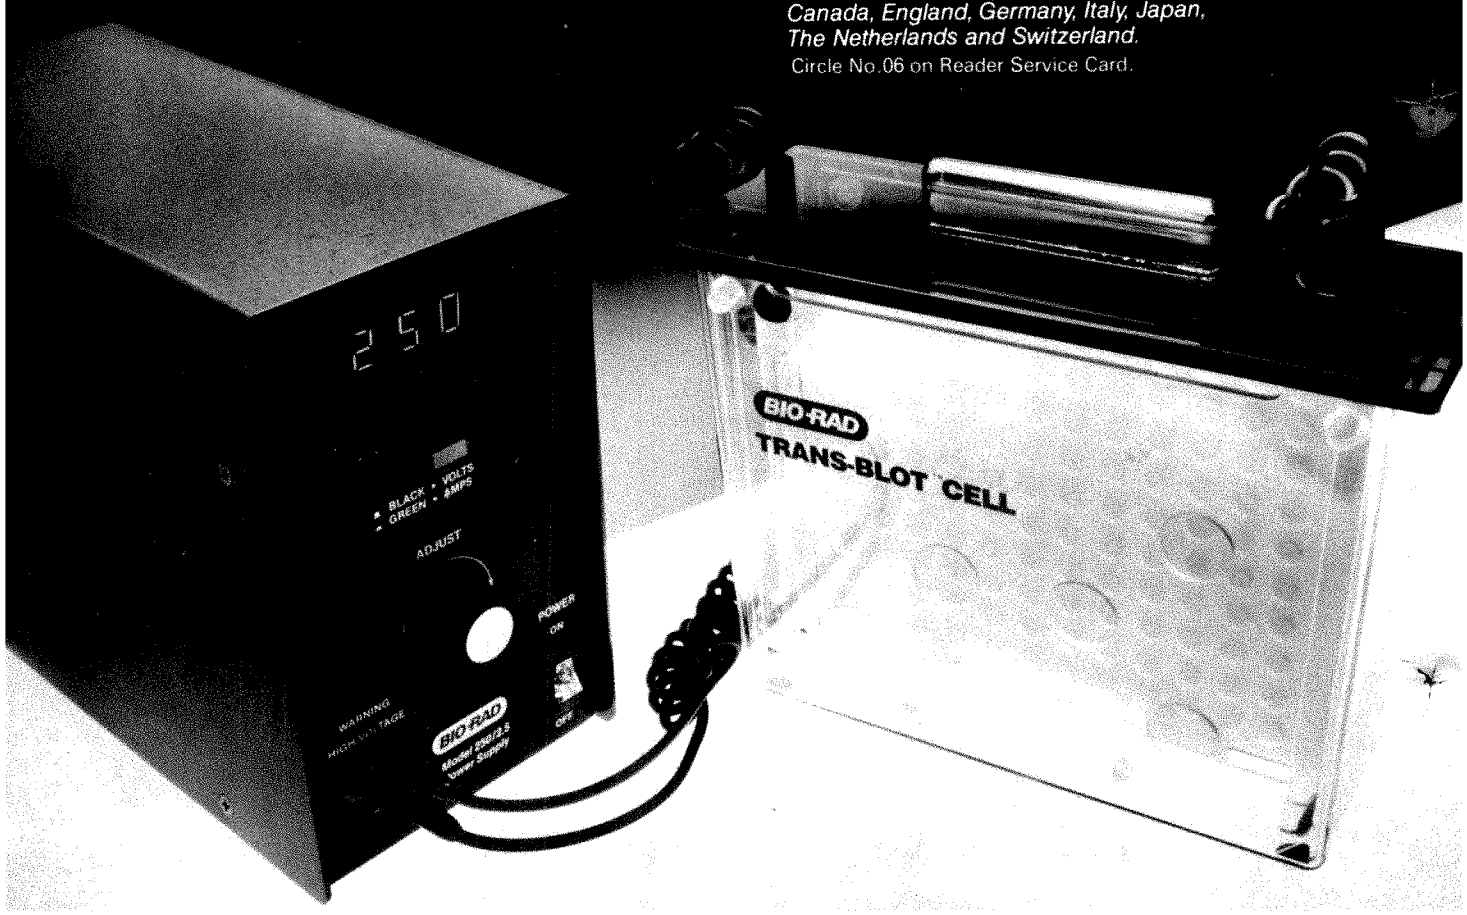
- Capable of supplying power for even the most demanding blotting experiments. No other supply can provide both high amps and volts simultaneously.
- Digital meter, regulated output and fan cooled, for easy viewing, performance and reliability.
- Dual outputs wired in parallel allow running of 2 blots simultaneously.
- Overload protected.
- Conforms to all relevant safety standards to protect operator.

New detection systems and transfer membranes

Completing the system, Bio-Rad offers

- Two rapid ways to perform Immun-Blot™ non-isotopic picogram level detection using affinity purified Goat anti-Mouse and Goat anti-Rabbit horseradish Peroxidase conjugates.
- New nylon-based membrane, Zeta-Probe,™ for efficient Western, Southern and Northern electro-blotting.
- All needed reagents, membranes and supplies, as well as comprehensive applications data and protocols.



Contact us for details.

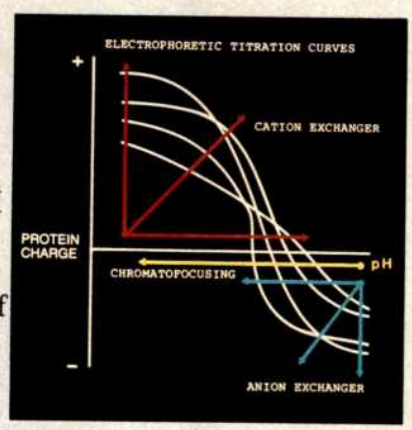
When you say "why FPLC" you are half way there ...

... because MonoBeads™ from Pharmacia is the state of the art in high performance media for separating and recovering biologically active molecules.

MonoBeads is a new generation pressure and pH stable chromatography matrix specifically designed for protein and peptide chemistry. MonoBeads is a beaded hydrophilic resin which is rigid and has the narrowest of any particle size distribution available today for chromatography.



Three derivatives of this monodisperse matrix are prepacked for high resolution in borosilicate glass columns, Mono Q™ HR 5/5 (strong anion exchanger), Mono S™ HR 5/5 (strong cation exchanger) and Mono P™ HR 5/20 (chromatofocusing). These columns are run with aqueous buffers at low back pressures, to separate labile biomolecules, analytically or preparatively, while retaining *biological activity*.

Glass columns prepacked with MonoBeads give you *high recoveries and high performance resolution in minutes*.

... so go all the way.

The inert glass columns together with the high performance MonoBeads provide you with a complete and optimized range of columns for the separation of proteins according to charge. Electrophoretic titration curves can indicate which column and pH will give optimal resolution of a particular protein in the sample mixture. Different combinations of the three exchangers plus varied pH, ionic strength and gradient shape offer you innumerable possibilities for separating complex biomolecules.

- High recovery of biological activity
- High performance prepacked glass columns
- Wide pH range (2–12)
- Aqueous buffers and organic solvents
- Three dimensions: anion exchanger, cation exchanger and chromatofocusing
- Analytical and preparative (1 μg–5 mg/peak)
- Rapid separations
- Economical

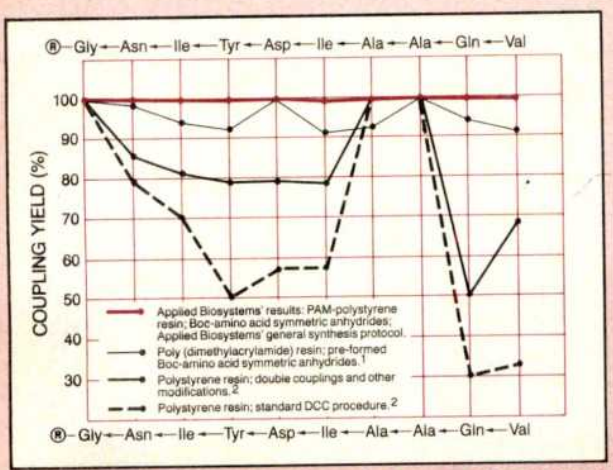
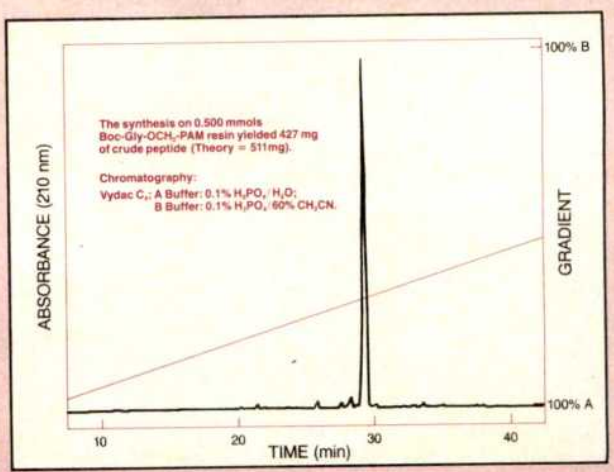
BIOSYSTEMS UPDATE



A New Approach to Automated Peptide Synthesis

Applied Biosystems is pleased to announce the first instrument designed for high efficiency peptide synthesis. The key to the high coupling yield of the Model 430A Peptide Synthesizer is an activation unit which converts the amino acid to a very efficient acylating species immediately prior to the coupling step. The defined protocol has been optimized for general peptide synthesis, but the fully programmable system allows straightforward adaptation to other chemistries.



Cycle times with the general synthesis protocol are approximately one hour. A single loading of protected amino acids, reagents, and solvents will give up to 50 synthesis cycles. To insure high coupling yields, Applied Biosystems manufactures and supplies all synthesis reagents.

The data below summarize the results of the synthesis of the decapeptide Acyl Carrier Protein (65-74). These results illustrate the combined capabilities of the novel automated synthesis procedure and the high quality peptide synthesis reagents and loaded resins.

The new Model 430A Peptide Synthesizer was introduced at FASEB, Analytica and at the ASBC Meeting. For more information, circle No. 08

APPLICATIONS REPORT NUMBER 3

ULTRAPURIFICATION OF MONOCLONAL ANTIBODIES

Your present purification methods may be missing something.

Even electrophoretically pure monoclonal antibody preparations are frequently contaminated with antibodies of unknown specificity.

With the new Bio-Rad high performance hydroxylapatite (HPHT) protein purification system,* these contaminants can be detected and removed—quickly and easily—either directly from raw ascites or from immunoglobulin fractions purified by other methods.

Consider the evidence.

The experiment at left illustrates the separation of an electrophoretically pure immunoglobulin preparation into different species with the Bio-Rad HPHT system. Using the HPHT system, you can purify the antibody from as much as 40mg (~1ml) of total protein present in raw ascites per injection.

Consider the advantages.

Obtain the purity you need for therapeutic applications and dramatically increase the specific titer of your antibody for the best possible sensitivity and specificity in immunoassays and other applications.

Make sure your monoclonal antibodies are ultra-pure.

Contact our applications scientists at **(800) 4 BIO-RAD** for complete information on the new HPHT protein purification system.

TWO-VOLUME PAPERBACK EDITION NOW AVAILABLE

Molecular Biology of Tumor Viruses, 2nd Edition

RNA TUMOR VIRUSES

Monograph 10C

Edited By
Robin A. Weiss, *Institute of Cancer Research, London*
Natalie M. Teich, *Imperial Cancer Research Fund Laboratories*
Harold E. Varmus, *University of California, San Francisco*
John M. Coffin, *Tufts University School of Medicine*

Since the original edition of *RNA TUMOR VIRUSES* first appeared two years ago, there has been an enormous increase in the amount of detailed information and a wealth of novel observations in retrovirology. Several progenitors of retroviral oncogenes have been implicated in human cancers, protein products of many oncogenes have been described, several new *v-onc* and *c-onc* genes have been identified, and sequencing of many retroviral genomes, LTRs, structural genes, and *v-onc* and *c-onc* genes has been completed. The result is a TWO-VOLUME PAPERBACK EDITION of *RNA Tumor Viruses* that is almost double the size of the original edition. Volume 1 contains the original text and remains the standard textbook for graduate students. The developments of the past two years, including a new chapter on human oncogenes, are recounted in Supplements to the original chapters. These appear in volume 2 along with new, expanded appendixes of extensive sequencing results and structural and restriction maps. Thus, those who already own the original edition need only purchase the second volume to update their hardcover copy.

Contents

Volume 1

Introduction: Origins of Contemporary RNA Tumor Virus Research; Taxonomy of Retroviruses (N. Teich); Experimental Biology and Assay of RNA Tumor Viruses (R. Weiss); Structure of the Retroviral Genome (J. Coffin); Replication of Retroviruses (H. Varmus, R. Swanstrom); Protein Biosynthesis and Assembly (C. Dickson et al.); Genetics of Retroviruses (M. Linial, D. Blair); Pathogenesis of Retrovirus-Induced Disease (N. Teich et al.); Functions and Origins of Retroviral Transforming Genes (J. M. Bishop, H. Varmus); Endogenous Viruses (J. Coffin); The Search for Human RNA Tumor Viruses (R. Weiss)

Volume 2

Supplements to original chapters; Human Oncogenes (C. Marshall); Appendixes—Nomenclature; Nucleotide Sequences Complemented with Functional and Structural Analysis; Restriction Endonuclease Maps; tRNA Primers; Amino Acid Sequences of Retroviral Structural Proteins

How to get custom DNA or peptides from a telephone—*Fast!*

Call Biosearch.

Our business *is* synthetic DNA and peptide chemistry. And we've automated these chemistries to supply you with high quality, custom oligonucleotides and peptides for prices that will fit your budget and need for fast delivery.

Custom DNA—Choose from three new pricing options to suit your budget and requirements for speedy delivery. For example, save up to 25% on our regular price if you sequence your custom nucleotide. And fast? Depending on the option you choose,

we can deliver a custom product within **ten days!**

Custom peptides—We guarantee confidentiality, sequence integrity, on-time delivery, and high purity at very competitive prices. Each peptide is shipped with complete analytical data for product verification. Call us with the sequence you need and we'll furnish a quote the same day.

Additional discounts are available for multiple orders. So . . . to get the best custom DNA or peptides from a telephone,
call Biosearch. Today!

New machinery for UK science

After only a year, the new-style administration of British academic science has more enemies than friends. The best course would be to redesign the machinery, the best hope is that it will be improved.

THE British, humiliated earlier this week at the English national sport of cricket by a bunch of skilful Caribbeans, seem also to be heading for defeat in their next most gripping preoccupation, that of reorganizing the administration of publicly supported science. Although new arrangements for deciding how the budget for basic science should be distributed were introduced only at the beginning of 1983, the new system is already in trouble. The focus of general discontent is the Advisory Board for the Research Councils, the committee whose indispensable function is to tell the Department of Education and Science how the annual science budget for academic and basic research should be divided among its traditional recipients — five research councils, the Royal Society and the British Museum (Natural History).

For much of the time since the early 1970s, the board was a cosy committee of the executive heads of the research councils, the chief spenders of the science budget, accompanied by the chief scientists of other government departments. A select committee of the House of Lords then complained that the board had become too ingrown, too idle and too unreflective. The government declined to follow the advice then given that there should be a part-time minister with separate responsibility for civil science, but instead agreed that the board should be strengthened (which in practice has meant enlargement) and encouraged to take a wider view of the conduct of civil science. A year ago, those involved were full of hope that the new arrangement would function well. What has gone wrong?

Complaints abound, not the least of which is that the board has been turned into yet another talking shop of all the talents. Certainly it is too large to take decisions, or even to give advice decisively. The new chairman of the Economic and Social Research Council, Sir Douglas Hague, seems subversively to have been making this point to his colleagues in the past year, and cogently. To say the least, it is a sign of weakness that the board, for all its distinction, when faced with the question raised by the Science and Engineering Research Council whether the United Kingdom should continue to contribute towards the CERN high-energy physics laboratory, could not decide off its own bat but had instead to set up yet another committee, prolonging uncertainty by at least a year. Another difficulty that has arisen is that the research councils, whose chief executives remain members of the board, must turn themselves into supplicants of their lay (and less expertly informed) colleagues when they bid for their shares of the cake (most recently at the meeting on 7 June). It is galling to those concerned that the advice eventually given to the Secretary of State for Education and Science should be based on only second-hand knowledge of what the councils actually do with the money they are given to spend. The difficulty is especially acute when, as now, marginal changes in their budgets may determine the survival of particular laboratories.

Benefits

Before resentment of the present arrangements gets out of hand, its benefits should at least be acknowledged. For the past two years, the board has operated more publicly than previously, publishing both its advice on how the budget should be divided and (earlier this year) its sour response to the denial of extra funds. With luck (and time), it could yet become a means by which the British research community's sense of how limited resources should be used could be channelled more effectively into the conduct of public policy on civil science. The board has also, with its tiny and poor secretarial resources, commissioned some useful studies on questions such as the relationship between research institutes and universities, and between university research and industrial sponsorship. In passing, as part of its cake-cutting, the board has also pushed the research councils towards a greater concern for university research than for their own institutions. And while there is no prospect that, on present form, it will become collectively so knowledgeable about the pattern of British civil science as to refute the research councils' charge that it is inexpert, the need for such an all-knowing institution is itself questionable.

These frustrations would no doubt have been borne more easily in other, happier, times. If the British science budget were still growing every year, the great and the good would be able to supplement their advice to the Department of Education and Science with a few urbane comments on the opportunities lying ahead. Bad tempers have made their appearance only because those who spend the science budget, chiefly the research councils, are unable to satisfy the demands now being made on them by researchers seeking support for projects that are eminently worthwhile. It does not help that this year, the board has been compelled to repeat the demand, refused last year, for extra funds, with only committee-style eloquence to help. But these are precisely the circumstances — likely to persist for many years — when an effective commentary on public policy for science is needed. The strains that have become apparent are indeed a proof that the system needs to be changed. Here are three directions for reform.

Reform

First, most modestly, the present arrangements could be made to function more effectively. To that end, the board should be given an adequate secretariat, one composed of people (not necessarily civil servants) who understand the problems it needs to tackle. While the essence of the board's task may be to cut the annual cake of public spending on science, it could then hope to do this more intelligently by finding out what happens to the funds that eventually find their way into the hands of the research councils. Many obvious questions are unanswered. How many universities have set up research committees, as the board asked them two years ago, to plot a strategy for their institutions' research? (Some say that the answer is just one.) Are public research institutes collaborating more effectively with universities now that they have been bidden to do just that a dozen times? (Some are, some are not.) What is the effect on the pattern of academic research in Britain of the stream of exhortation by the British Government in favour of this, and then that, brave new opportunity? (Mostly baleful.) And is it true that, for reasons that are as much psychological as financial, the British research enterprise has lost its capacity to compete with others? (Probably yes.) What are the prospects — and problems — of strengthening inter-European collaboration in ways that would economize in effort, not waste it? (Many, but unexplored.) Without means of dealing intelligently with these and related questions, the board continues to lose conviction — and friends.

Second, and more imaginatively, the board could be given wider terms of reference. In the curious British way, its sphere of interest is confined to scientific research supported by the

Department of Education and Science. Other parts of the public research enterprise are within the purview of a different committee (the Advisory Council for Applied Research and Development), which lately has not surfaced in public view. There is no committee to ask questions about the relationship between civil and military research. It would still need a better secretariat. It could deliver the annual gobbet of advice to the Department of Education and Science more convincingly if it knew more directly what research is being sponsored by other departments. And it could avoid the present frustration by considering how the coordination between the disjoint halves of British public science could lead to greater effectiveness. In the real world, this is the most to hope for but the least for which to clamour.

Third, outrageously, is the remedy suggested in 1982 by the House of Lords: whatever apparatus there may be for giving specialized advice, let there be a minister specialized at receiving it. As things are, the British Government has built itself into a box. Lacking specialists within the civil service (as in West Germany) or an intimate relationship with the government's own specialist agencies (as in France), departments turn to advisory committees for advice which may be taken seriously when it is palatable and otherwise ignored. The downfall of the Advisory Board for the Research Councils can be traced to the occasion last year when it asked for more and was denied. Even if the Prime Minister rather than the Secretary of State was the one who finally said no, the doctrine of collective responsibility lumps the board in with all other dissident disappointed claimants on public funds — local authorities, schoolteachers and the unemployed. There is nobody to put the case, within the government, that the once and for all decline in the quality of the British research enterprise which is now on the cards will cast an even longer shadow. Within the political system to which the British are attached, but which allows ministers to carry only one torch at a time, only the designation of a single-minded political standard-bearer can enable the arguments for rescuing British science to be heard. □

Claims to antiquity

Publishers like to claim either antiquity or modernity. Cambridge can boast of both.

CAMBRIDGE University Press last week celebrated what it calls its 400th birthday with a "Garden Luncheon Party and Great Exhibition", offering its guests the presence of Prince Philip, the chancellor of the university, some sunshine, a band and a menu from which strawberries, usually mandatory on these occasions, were absent. Cambridge boasts that it is the oldest press in the world with an unbroken history. Only 80 years after Gutenberg, Henry VIII issued Letters Patent in 1534 granting the university "lawful and incontestable power to print there all manner of books". Although the first book did not appear until 1584 — even then, too long an interval to be explained as normal publication delay — it was a single but crucial year ahead of Oxford University Press and three years before the Vatican Press. Confusing for students of priority disputes was a 500-year celebration held by the University of Oxford in 1978. That occasion, Cambridge says, marked the quincentenary of the first book to be printed in the city of Oxford, not by Oxford University Press itself.

In science publishing, Cambridge University Press has been strong in mathematics and physics. In 1713, a revision of Newton's *Principia Mathematica* appeared under its imprint. Its other authors included James Clerk Maxwell, Rutherford, Jeans, Schrödinger, Einstein and, more recently, Hawking and Chandrasekhar. Undoubtedly the best known of the contemporary works is Joseph Needham's mammoth *Science and Civilisation in China,* Volume 6, Part 2 of which was published in April. Legally the press is unique, formally a department of the university with the status of a charity. It thus pays no tax. The press is governed by the 18 members of the syndicate, appointed by the university, which must approve all publishing proposals. Mercifully, this apparently anachronistic constitution seems not to be inhibiting. □

Unwelcome precision

Last week's US missile test could destroy the ABM treaty.

STAR wars are becoming uncomfortably realistic. That is one reading of the successful test last week of the US ground-based missile system, based on the Minuteman antiballistic missile, in which a dummy missile warhead was successfully intercepted within hours of a crucial decision by the US Senate about continuing support for these and related projects (see p.660). But last week's test was no part of the comprehensive defence against other people's ballistic missiles that President Reagan has been canvassing this past year. Instead, it is part of what some may call the conventional Anti-Ballistic Missile (ABM) programme which, in the United States and the Soviet Union, has its origins in the early 1960s. The fact that the test (the fourth) succeeded is nevertheless a sign that the treaties which are the fragile reminders of the time, not so long ago, when the superpowers felt able to sign agreements with each other may be coming to the ends of their useful lives.

In 1972, when the ABM treaty was signed between the Soviet Union and the United States, the openly acknowledged incentive was the fear that, without such a treaty, the deterrent value of strategic forces would be eroded. If one power believed that it could destroy the other's missiles, it would be less fearful of making a first strike with its own. That the two powers should thus openly acknowledge the identity of each other's calculations of the psychology of nuclear war was in itself a triumph. The treaty offered a little more — the promise of a respite from ruinously expensive development. But now those benefits appear to be receding. Both sides seem certain to be spurred by last week's test to further development. Technically, there is no reason why the new US system should not be stretched so as to become a second antisatellite (ASAT) weapon, capable of destroying satellites in low orbits, and thus a partner for the US Air Force system called MHV, launched from F-15 aircraft and already tested. (The traditional rivalry between the US Army and the Air Force will, left to itself, ensure rapid progress.) But technically, again, the arguments of the early 1970s remain valid that no rocket-borne system of this kind can be a certain defence against ballistic missiles with several warheads.

The first casualty will be the ABM treaty. The signatories accepted limitations on the testing of these weapons, although research was to be allowed. The signs now, however, are that unrestrained testing will create the impression, on one side or the other, that the treaty is a dead letter. Then, that is what it will become. And in such a setting, the prospects of an agreement on more elaborate systems to be deployed for longer periods above the atmosphere of the Earth will be even smaller than at present. The United States, after all, has not yet launched as many antisatellite weapons as has the Soviet Union, which began to test its system as long ago as 1968. President Reagan will be able to certify to Congress whenever he likes that he has complied with the Senate's qualification of its grant of star-wars funds by saying that no agreement with the Soviet Union would be "consistent with the national security interests" until the United States has done at least as well. But by then, the Soviet Union will have provided further goals at which to aim.

The depressing reality of all this is that it will be at the least a waste of resources on both sides, and will be dangerous as well. While the star-wars idea is said (by some of those privy to what is planned) to be a technically interesting bag of innovations, nobody has been able to convince the sceptics that a star-wars defensive system could destroy a high proportion of the other side's missiles. And for as long as that remains the case, the course on which the Senate has allowed the US Administration to embark, and on which the Soviet Union is already engaged, cannot counter the objections raised against ABM defence in 1972: if there is a nuclear balance, it is bound to be upset. The irony, of course, is that the two governments were prepared to accept the logic in 1972. They should now follow suit for star wars. □

Australian uranium

Chance of policy change on nuclear fuel

Canberra

THE Australian Labor Government has been given an influential blessing for a change of policy on uranium exports. On 31 May, the Prime Minister, Mr R.J. (Bob) Hawke, presented to the federal parliament the report of a committee which argues that the mining and milling of uranium should continue and that the government should have authority to approve new mines and supply contracts.

If eventually adopted, the policy now recommended will represent a substantial change in the policy which the Labor Government has followed since its election. During the past year, the federal government has allowed existing operations and contracts to continue but has set its face against new enterprises. The new report argues not merely that the supply of uranium overseas should be increased but that Australia should participate in the enrichment of uranium, the reprocessing of nuclear fuel and, possibly, other steps in the nuclear fuel cycle.

These recommendations will strengthen Mr Hawke's hand in influencing uncommitted delegates to the Australian Labor Party (ALP) national conference next month, when strong opposition from the left is expected to the government's policy of allowing existing mining to continue, even under stringent supply conditions.

The 300-page report, *Australia's role in the nuclear fuel-cycle*, was prepared at Mr Hawke's request by the Australian Science and Technology Council (ASTEC), under the supervision of its chairman, Professor Ralph Slatyer, former Australian Ambassador to the United Nations Education, Scientific and Cultural Organization, when in November last year the government granted permission for the development of a new uranium mine at Roxby Downs, South Australia, potentially the world's largest.

The Slatyer report recommends that Australia, although not itself likely to use nuclear power, should accept that for many countries nuclear energy has become a fact of life. And since Australia owns 30 per cent of the uranium resources of the West, its contribution to nuclear non-proliferation should be enhanced by participation in the nuclear fuel cycle.

As a reliable long-term supplier of uranium, Australia would be in a position to influence the behaviour of other states, the report argues. Thus, by helping to ensure international energy security, Australia might reduce the motivation of other countries to engage in other steps of the fuel cycle, particularly reprocessing and fast-breeder development.

The compilers of the report are unconvinced that supplying uranium to nuclear weapons states frees other uranium for use in weapons (vertical proliferation). Denial of supply to such states, the report says, would be an empty gesture, scarcely affecting weapons programmes, since stockpiles are already adequate. Similarly, denial would not deter horizontal proliferation, since the political decision to develop nuclear weapons can in present circumstances be implemented by any country with sufficient determination and a reasonable scientific infrastructure. The absence of a civil nuclear industry would not prevent the manufacturer of nuclear weapons. In any case, the report adds, such a country is unlikely on efficiency grounds to rely on civil power reactors for the manufacture of plutonium.

Other recommendations include continued support for a nuclear weapons-free zone in the South Pacific and for an Indian Ocean zone of peace. Australia should seek to join the board of governors of the International Atomic Energy Agency and spell out the feasibility of regional treaties with South and East Asian countries along the lines of the Treaty of Tlatlelco. The regime should be strengthened by internationalizing the steps in the fuel cycle, but sensitive facilities, particularly enrichment and reprocessing plants, should be located in as few countries in the region as possible, Australia and Japan for example. There should be support for the moratorium on ocean dumping of low-level waste, and continued research on the Australian-designed ceramic Synroc, the most promising high-level waste form, but Australia should not be obliged to dispose of high-level wastes from Australian uranium.

For the government and Mr Hawke, everything now hangs on the outcome of the Australian Labor Party's national conference, which seems unlikely to endorse a uranium policy going beyond that now defined by the government party caucus at Canberra and which is opposed to further uranium mines after Roxby. A further difficulty for the government stems from the ban on uranium sales to France, intended as a protest against French nuclear tests in the Pacific, the latest of which took place on 17 June. Unless the tests end, the Labor Party is unlikely to relax its traditional view that Australian uranium should not be used for other people's bombs. This, the government fears, may lead to trade reprisals and even to a law suit at the International Court of Justice.

Jeffrey Sellar

US–China nuclear treaty

Congress makes difficulties

THE United States–China nuclear exchange agreement which President Reagan announced triumphantly in Beijing last April is almost certain to be postponed and may fall through altogether. The text of the agreement initialled in Beijing has not yet been submitted for congressional approval, and the administration is now conceding privately that the assurances on non-proliferation may not be explicit enough to satisfy Congress.

A State Department spokesman said last week that the text had been studied by the relevant federal departments, including the Nuclear Regulatory Commission, and found to comply with US law on the transfer of nuclear technology. But he also revealed for the first time that the administration had sought renewed talks with the Chinese Government "to ensure a full mutual understanding".

What appears to have happened is that the administration was so eager to close the deal while President Reagan was still in Beijing that it fudged the two issues that had already dragged out the negotiations for more than two years. One is the status of China's promise not to help other nations to acquire nuclear weapons; the other is a requirement that China must seek US approval before using nuclear fuel from American-supplied reactors in nuclear warheads or for warship propulsion.

Persistent allegations in Congress that China has assisted Pakistan in a nuclear weapons programme have been a major reason for Congress's lukewarm attitude. Last week, however, the *Washington Post* published a startling news story maintaining that the US delegation in Beijing had decided to accept verbal assurances on non-proliferation from Premier Zhao Ziyang instead of insisting on explicit written assurances in the text of the agreement. There had previously been reports that the thorny problem of China having to ask for US permission to use reprocessed fuel from US-supplied reactors had been overcome by "clever drafting".

Just why the administration has had second thoughts about the adequacy of the safeguards it claimed to have negotiated successfully last April is a mystery. Officially-inspired leaks suggest that new intelligence information has confirmed China's role in Pakistan's nuclear weapons programme.

It is just as likely that the Nuclear Regulatory Commission and other agencies with close experience of Congress's views on nuclear proliferation have concluded that the agreement is too vague to be approved in its present form.

Peter David

Electron accelerators

Southern US project delayed

Washington

THE group of US universities unexpectedly selected last year to build a major new electron accelerator has begun hesitantly. After a year, the project still has no director and, in the absence of a definite estimate of construction costs, Congress is balking at appropriating the full amount requested by the Department of Energy (DoE) for the project, now known as the Continuous Electron Beam Accelerator Facility.

The Southeastern Universities Research Association (SURA), a consortium led by the University of Virginia, was chosen last year by the Nuclear Science Advisory Committee (NSAC) to build the new machine at a site in Newport News, Virginia.

The decision set off a long political battle when Argonne National Laboratory, which had hoped to win the committee's recommendation, took its case directly to Congress and the Secretary of Energy. Traditionally, the physics research community has accepted as final the decisions of NSAC, which is made up of nuclear physicists and is formally an advisory body to DoE.

The fight between Argonne and SURA may have played a part in the slow start of the project. James McCarthy, a professor of physics at Virginia who is acting director of the accelerator, said that last year's fight gave the project a "political visibility" which provided greater congressional scrutiny, even after the Secretary of Energy had settled the matter last summer in SURA's favour.

The House of Representatives approved the administration request of $5 million for research and development and $2 million for construction in fiscal year 1985, but the Senate, complaining about not having a detailed cost estimate or a clear justification for the project, cut the figures to £2.5 million and zero respectively. At the bidding of Senator Bennett Johnston, the senior Democrat on the Senate Energy Committee, the Senate also asked DoE to provide a five-year plan for nuclear physics that would include the options of going ahead with the SURA accelerator or dropping it.

Although SURA would still be allowed to go ahead with the detailed architectural and engineering design work it had called "construction" in its budget request, the Senate's elimination of construction funds serves notice that the future of the project is by no means certain. It is generally difficult to kill a project once it has been accorded a line-item construction authorization.

SURA originally proposed a budget of $20 million for next year, but backed off in the face of congressional complaints that the ultimate cost is uncertain. SURA's original proposal was that the total cost would be about $100 million, but NSAC, considering that unrealistic, increased it to $150 million. In testimony to Congress this spring, McCarthy mentioned a figure of $225 million. Although most of the increase can be explained by inflation, there appeared to be some new items (such as increased office space).

Some of the Senate's caution may stem also from worries about whether the United States can afford such projects if it is to go ahead with the massive proposed Superconducting Super-Collider, which may cost $3,000 million.

D. Allan Bromley of Yale University, who chaired the NSAC panel that recommended SURA, said that the physics community still considers the project to be a first priority. He said that although there is widespread disappointment that more progress had not been made, much of the trouble is a result of a "Catch-22" dilemma; SURA cannot attract a director without assured construction funds, and cannot get assured construction funds until it has a director and a definite design.

According to McCarthy, an offer has been made to a "leading accelerator physicist", who will decide by 1 July whether to accept the directorship. That date is also when SURA will receive $1 million appropriated by the Virginia legislature and an additional $1 million that Congress has just allocated to DoE to "reprogram" the project. The funds will allow SURA to begin filling 9 senior and 15 junior positions on the scientific staff.

Stephen Budiansky

Computer theft boom

Washington

A SURVEY of US companies and government agencies has provided the first systematic evidence of how widespread computer crime has become. Of the 283 organizations that responded, 72 reported "known and verifiable" losses as a result of computer crime in the past 12 months. The average loss was in the range of $2–10 million, but one organization reported losing more than $100 million.

The survey, conducted by the American Bar Association, defined "computer crime" quite broadly to include embezzlement, theft of software and even the unauthorized use of computers for personal programming. The last was found to be the most common "crime", reported by 62 respondents; next in line was the theft of software, reported by 45, and use of computers for theft of assets (44).

While it is impossible to extrapolate the survey's results, the bar association states that "given the small number of organizations reporting these large losses . . . the total loss figure nationwide would appear to be enormous." The survey was sent to 1,000 organizations Two-thirds of the identified perpetrators were employees of the organization, most often computer programmers.

The bar association called for the enactment of federal legislation against computer crime to aid in the reporting and prosecution of such incidents. Existing statutes that may be applicable, such as wire fraud, trespassing and embezzlement, carry penalties that the association said are often "far from commensurate" with the seriousness of computer crimes.

Academic ethics

Perils of scholarly plagiarism

Palo Alto

A distinguished Stanford University professor resigned as chairman of the department of medicine last week after a university ethics committee found him guilty of "grossly negligent scholarship". Dr Kenneth Melmon, who keeps his faculty position, was censured for plagiarizing roughly a quarter of a chapter in an endocrinology textbook. The committee said that no fraud had been committed and that Dr Melmon had had no conscious intent to deceive.

Trouble arose when the publisher of another medical text, *The Pharmacological Basis for Therapeutics*, found that large portions of that had appeared in Dr Melmon's chapter contributed to the endocrinology book (see *Nature* 5 April, p.489). At the time, Dr Melmon said his friend and editor of the endocrinology book, Dr Robert Williams, had urged him to use portions from the pharmacology book, promising that permission and attributions would be secured. Dr Williams died, however, while the endocrinology book was being edited and his personal papers were later destroyed.

The Stanford ethics committee now says that it accepts Dr Melmon's explanation but has nevertheless censured him for his "recklessness" and "carelessness in dealing with the intellectual properties of others". He violated "the fundamental norms of the academic profession".

Dr Melmon was responsible for ensuring that proper attribution was incorporated into the chapter, the committee says; he should have checked that it was done properly.

Dr Melmon said he was resigning his chairmanship because "the mistake was a serious one". A clinical pharmacologist, he holds the Bloomfield endowed chair in Stanford's department of medicine and is a member of the Institute of Medicine of the National Academy of Sciences.

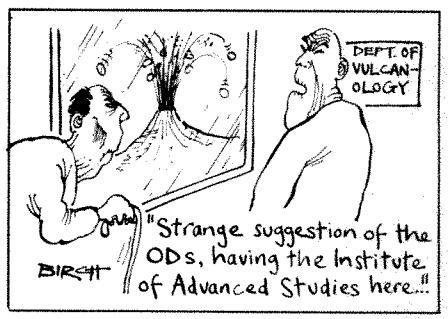
Sandra Blakeslee

Japan's unemployed PhDs

Unused researchers to arms

Tokyo

JAPAN's ever-increasing numbers of unemployed postdoctoral researchers are banding together to find ways of making life a little easier. But there is little they can do to increase their chances of actually finding an academic job.



The number of "overdoctors", or "ODs" as unemployed postdoctoral researchers are known in Japan, is now at an all-time high. (Overdoctor is an apt English word which the Japanese have invented for themselves.) There are at least 5,000 waiting for jobs in university departments, many of whom have now been waiting for more than ten years.

Japanese universities, unlike many of their Western counterparts, officially allow students who have completed their doctorates to stay on in their laboratories (upon payment of a monthly fee of around £40) to continue unpaid research while looking for a job. In some cases, such as the physics department of Kyoto University where there are now over a hundred, they outnumber the full-time teaching staff. Physicists, particularly theoretical physicists, have been hardest hit, with more than a thousand ODs nationwide, followed by humanities, social science and agriculture.

To ease their plight, Dr Teruhisa Komatsu, an oceanographer from Kyoto University, has set up an OD Society and has found himself 200 members in just a few weeks. The society's chief aim is to keep ODs going, both financially and psychologically, while they are looking for *arubaito* (part-time work, this word stolen from the German *arbeit*) — usually teaching in a cramming school, translating technical reports from European languages or helping with the sophisticated analysis of university entrance requirements needed to help high-school students to pick a suitable university. The society plans to help find the best jobs for its members and also to remove the ODs' sense of isolation by arranging conferences for the presentation of their work.

Life as an OD is by no means easy. Although most ODs are in their late twenties, surveys show that only a little over half are married (compared with nine-tenths of the general population of the same age). Average incomes are exceptionally low, only a little over £3,000 a year before tax.

A particularly cruel irony faces those who never find academic jobs. During their postgraduate study (two years for a master's course followed by three years of doctoral research), students must pay their own fees of around £400 a month as well as their own living expenses. There are no cosy European-style grants to cover the cost of education. As a result, almost all students take loans from semi-governmental bodies. While the loans need not be repaid by those who find a university job, the unemployed are left with a huge bill for their education.

Neither the Ministry of Education, Culture and Science (MESC) nor university staff are taking steps to ease the OD problem, mainly because everyone lays the blame at someone else's door. One ministry official sums it up by saying that "they (the ODs) should seek work in practical, non-academic fields, instead of keeping their sights on a life in the ivory towers".

Certainly it is a common view that ODs bring about their own problems by "refusing" to work in industry, insisting instead on waiting for the impossible. There is some truth in this charge. Among physicists, for example, there are many who have had experience of computer programming and are in demand by industry. But it is nonsense to suggest that most ODs can easily find work of any other kind than the part-time work they already do.

Industry in Japan has a strong preference for graduates fresh from university, who can be trained in a company's own ethos. Even school teaching is hard to enter, with an upper age-limit for new entrants of around 28–32. Particularly hard-hit are the many ODs with training in agriculture, for there is no related practical field into which they can go. Small wonder, then, that the two most favoured routes out of the OD trap are a fellowship to a US or European university — and journalism.

The only long-term Japanese solution must be an expansion of the universities, but this is a political question. And the government intends to squeeze all the ministries again next year (with the exception of defence). Hopes of university expansion must for the time being remain in the realms of fantasy. **Alun Anderson**

Academic demography awry

THE OD problem results from the massive expansion of the universities in the late 1960s, which created many new doctoral schools. With the oil shock, the expansion of the universities has been halted, but there are fewer job opportunities for researchers from the new schools.

So why cannot the Ministry of Education, Science and Culture (MESC) reduce the flow of graduate students, or at least redirect them into areas, such as computer programming, where highly-trained people are needed? Unfortunately, the Japanese system is far from flexible. Once permission has been gained for the establishment of a doctoral school, there is little further MESC can do to control it. As no grants are given directly to students (and loans are easy to obtain), it is hard to redirect students quickly into new subject areas. And professors, enjoying considerable power under the "chair" system, will fight tooth and nail to prevent government meddling in their affairs.

Thus arises a common view within MESC that professors worried about the OD problem should voluntarily reduce their student intake and coordinate activities with others in their field to take account of future forecasts. Some professors have indeed done exactly this. But because teaching loads are high, it is virtually impossible for any ambitious professor to carry out a research programme without graduate students to help.

The contraction in the universities that has provoked the OD problem has also caused another, potentially more damaging, academic problem, one which MESC seems again to be ignoring. The slowdown in the recruitment of new researchers has seriously distorted the age structure in the university research community. Simulations conducted by Kenichi and Kaoru Aoki of the Kyoto University Research Institute for Fundamental Physics show that, by 1991, the median age of university staff will peak very sharply at 48. By 2001, the distribution will be bimodal with the larger peak at age 58.

European countries, particularly West Germany, are no strangers to this problem. The difference is that in Europe studies are being made by official bodies rather than being left to private individuals and steps are being taken — such as the United Kingdom's "new blood" scheme — to ensure that there are enough young workers at universities.

Drs Aoki hold that Japan just does not take a long-term view of scientific research planning — day-to-day economics are the prime determinant.

Postdoctoral fellowships, at present non-existent in Japan, could bridge the immediate shortage of young university workers until retirements begin to ease the situation. The Aokis claim that with such fellowships, an average expansion of 1,800 university posts a year, well below the 1960s peaks when 5,000 new jobs a year were being created, would give the universities a very healthy age structure. Alun Anderson

Weapons in space

ABM test persuades US Senate

Washington

LAST week's interception of one Minuteman missile by another at an altitude of more than 100 miles was a feat of exquisite political timing. The successful test was announced by the Department of Defense at the beginning of a week in which the Reagan Administration's plans for testing a new antisatellite (ASAT) weapon and stepping up research on the proposed "star wars" nuclear defence system faced major congressional hurdles. In the event, the Republican-controlled Senate agreed to give the ASAT test an amber light. And Congress now seems certain to give the administration much if not all of the $2,000 million it wants in 1985 for research on ballistic missile defence.

Of the two space weapon initiatives, the more pressing from the administration's point of view is the ASAT test. The Air Force has already developed a sophisticated aircraft-borne satellite interceptor (see *Nature* **308**, 576; 1984), but the House of Representatives voted last month to block tests against targets in space for a year or for as long as the Soviet Union continued a moratorium on tests of its own weapons. In both houses, there is strong feeling that talks on an ASAT ban should be resumed, despite the administration's insistence that no such ban could be adequately verified. And in a piece of deft timing of his own, Soviet President Konstantin Chernenko again urged the United States to negotiate an ASAT ban before it was "too late".

To discourage the Senate from following the example of the House, President Reagan's Senate allies arranged a closed session in which senators received intelligence briefings on the state of Soviet ASAT technology. They are said to have been told that, in addition to its well-publicized ASAT interceptor, the Soviet Union now has the means to cripple US satellites with a laser beam from an Earth station or by jamming their radio communications.

A day later, the Senate voted by 61 votes to 28 to allow the ASAT tests to proceed provided only that the President shows that he is trying to negotiate "the strictest possible limitations on antisatellite weapons consistent with national security interests of the United States".

The effect of the Senate resolution, which will have to be reconciled with the position of the House in a conference committee, is to require some action by the administration that demonstrates a wish to prevent an arms race in space. But it is clear from the mood of the debate that a symbolic gesture will suffice. As long as Mr Reagan certifies that the ASAT tests are vital to national security, and will not represent an "irreversible" block to negotiation, he will be allowed to test the new weapon.

Whether the President will take up the option in a hurry is another matter. The administration is becoming uncomfortably aware of growing public concern about the prospect of an arms race in space. So is the Democratic Party; its national chairman, Mr Charles Manatt, said last week that the presidential election in November will give voters a chance to ponder the "frightening choices" entailed in the administration's plans for the militarization of space. President Reagan is under pressure from his own party to show some flexibility on arms control before the election; by the end of last week the administration was already hinting that it might be willing to discuss some limitations on ASAT development.

The short-term ASAT question has not entirely distracted attention from "star wars". While Congress appears still to be willing to underwrite the preliminary research called for in the 1985 budget, organized opposition to the concept is gathering pace. A "national campaign to save the antiballistic missile (ABM) treaty" was launched this week by a committee of senior politicians and scientists, including former President Jimmy Carter and former defence secretary, Robert McNamara. In an opening statement, the committee claimed that the expanded star wars testing programme requested by the administration will "soon collide" with the restrictions imposed by the ABM Treaty.

Meanwhile, in a bizarre coda to the political debate, the technical debate over the feasibility of the star wars programme is becoming increasingly unfriendly. Deputy Defense Secretary Howard Taft has taken the extraordinary step of asking the Office of Technology Assessment to withdraw a technical memorandum on the subject written by Dr Ashton Carter of the Massachusetts Institute of Technology (see *Nature* **309**, 485; 1984). Mr Taft claims that the memorandum, which said the prospect of a near-perfect defence against nuclear attack was "remote", had subsequently been criticized on technical grounds by four independent review groups.

The Pentagon clearly expects last week's Minuteman interception to cut some ground from under the feet of those who doubt whether a defence against ballistic missiles is feasible. However, most critics of the star wars concept have already acknowledged that the interception of nuclear warheads in midcourse is feasible. Their objection is that a nuclear attack would involve so many missiles and decoys that such defences would be overwhelmed. The Office of Technology Assessment study therefore focused on the prospects for destroying missiles in their boost phase, before they could spawn their mutiple warheads. It concluded that most of the novel technologies required could be countered with relative ease.

Peter David

US Naval Observatory

Research at risk

Washington

THE US Naval Observatory, one of the oldest government scientific institutions in the United States, is in trouble, according to the National Academy of Sciences. Short of funds and overburdened by its role as a support agency, the observatory's basic research capability is in jeopardy, according to a new study. Some divisions of the observatory are "one man deep", according to Lee Hunt of the National Academy staff, and are "struggling to provide the bare minimum of services". Scientists often have to act as administrators and technicians as well, all of which leaves little time for basic research.

The primary mission of the observatory is what it always has been: providing data to aid navigation. Much of its work at present, for example, involves calibrating

atomic time standards and carrying out the observations needed to adjust the International Atomic Time scale for astronomical and navigational use.

But the observatory has also established a solid scientific reputation. The study notes the observatory's longstanding work on visual double stars, now in jeopardy for lack of manpower, and its determinations of parallaxes of faint stars — data that "effectively define our knowledge about luminosities, colours and tangential velocities of faint stars in the neighbourhood of the Sun". "Too much of the astronomers' time must go toward technical support activities", the study says, but Hunt put the point more directly: "You find directors sweeping floors."

The shortage of manpower is apparent in the study's recommendation on the double-star programme. If "one other person were able to take over clerical jobs", the study says, "the staff would be able to do much needed work on new technology." Hunt said that the study panel felt that continued excellence in basic research was vital to attract qualified scientists and to keep them in the mainstream of science.

The observatory has suffered not so much from budget cuts as from benign neglect. But the consequences are just as serious, the academy panel said. "No action at this time is a decision to erode the quality of staff and the services of data and information it provides."

Stephen Budiansky

UK medical research

More MRC units threatened

THE parlous financial position of Britain's Medical Research Council (MRC) is obliging the council to reconsider the future of any research to which it is not "irrevocably committed". The futures of three research units supported by the council are now described as "under review" following critical reports by visiting parties that, in some cases at least, recommended the council to consider closure.

The council said that a decision had been taken "in principle" to close its unit of neurochemical pharmacology at Cambridge (see *Nature* 7 June, p.486). But, as if to advertise that British medical research is not completely moribund, the council has also announced a new research unit to undertake laboratory studies of tuberculosis.

Surprisingly, the location of the new unit has not yet been finally decided, although the probable choice will be the Royal Postgraduate Medical School at Hammersmith, London. The new unit will replace two existing units in London, one at Hammersmith and one at the Brompton Hospital, Fulham, which are to be closed when their directors retire shortly.

The formation of the new unit signals a shift away from the study of the effects of tuberculosis on communities and of chemotherapy towards the use of new techniques, including recombinant DNA technology and monoclonal antibodies. The director is to be Dr Juraj Ivanyi, now head of experimental immunobiology at Wellcome Research Laboratories.

The three units whose future is uncertain are the Biostatistics Unit at Cambridge, the Pneumoconiosis Unit at Llandough Hospital in Penarth, South Wales, and the Mineral Metabolism Unit based in Leeds. A report by a regular visiting group to the Pneumoconiosis Unit has recommended closure, and the matter is to be considered shortly by MRC's Physiological Systems and Disorders Board. There has been a cloud over the future of the unit for some time, but the recommendation to close it was still a surprise to staff, who say they will be able to enter pleas for continuation when the board's recommendations, together with the unit's responses, are formally considered by MRC. The unit has no director in post at present, thus facilitating any closure decision.

The Mineral Metabolism Unit is also without a director, but its acting director, Dr M. Peacock, seems unwilling to accept that closure is one option to be considered by the disorders board. The unit's work on osteoporosis and adrenal stone disease is in line with recommendations of an international review of calcium in metabolism, and Dr Peacock is confident that MRC will find "no scientific grounds" to close the unit, although there have been some recent staff reductions. Much the same applies to the Biostatistics Unit, where interviews for a replacement director for Dr I. Sutherland have been called off at short notice.

Tim Beardsley

No sale yet for UK chip-maker Inmos

THE British Government is apparently still undecided about how it should introduce private capital into Inmos, the state-backed semiconductor manufacturer. The company, which started to trade profitably in the final quarter of 1983, has been provided with government capital of £65 million and loans and guarantees worth £40 million, and the Secretary of State for Trade and Industry, Mr Norman Tebbit, is keen to reduce the strain on the public sector borrowing requirement.

Earlier this month, Mr Kenneth Baker, Minister for Information Technology, said in the House of Commons that the government had vetoed a private share placing organized by the company that would have raised £30 million, on the grounds that the terms were not sufficiently attractive. Mr Baker's answers to supplementary questions made it clear that the government is anxious that Inmos technology should continue to be accessible to British industry and that there should be a commitment to continued development and expansion of Inmos's activities in Britain.

More recently, Thorn EMI has made public its offer of £10 million for a share of the company, an offer which Inmos's chairman Sir Malcolm Wilcox described as "very interesting". But the matter is still under consideration by the Department of Trade and Industry, which oversees the nominal holder of public shares in Inmos, the British Technology Group.

The US communications group AT&T (American Telephone and Telegraph) is also now bidding again for Inmos. An approach by AT&T was rejected by the board of Inmos in February, but negotiations are now under way directly with the government. AT&T has, as a nod towards the principle of keeping some of Inmos's activity based in Britain, agreed that some of its research and development activity might be carried out by ICL, the British computer company. AT&T is understood to have made an offer of £45 million for the whole company, a figure regarded as derisory by Inmos management.

Inmos is now making a monthly profit of around £1 million and has great hopes for the future with its revolutionary "transputer" chip. Tim Beardsley

Neural tube defects

British vitamin trial starts slowly

THE controversial British clinical trials of vitamin supplements in the prevention of spina bifida and other neural tube defects has begun, but on a much smaller scale than originally intended. A progress report issued last week said that so far the Medical Research Council (MRC) has recruited 132 women to the trial, still far short of the 2,000 target.

Even so, MRC says it is reasonably confident that recruitment will accelerate as new centres join the study. So far, physicians at a total of 16 medical centres in the United Kingdom and 12 overseas have agreed to take part, all with the approval of their local ethical committees.

The decision to conduct control trials with vitamin supplements was taken in December 1982, partly because of research by Professor R.W. Smithells at the University of Leeds which seemed to show that neural tube defects might be prevented by vitamin and particularly folic acid supplements before and immediately after conception. To separate the effects of folic acid from those of other vitamins, MRC advocated clinically controlled trials with randomly selected patients.

The trial has been controversial because the four groups of women to which volunteers are assigned at random includes one to whom only a placebo will be administered. During the past two years there have been complaints that the use of a placebo group is unethical in the face of *prima facie* evidence that vitamin supplements will prevent neural tube defects, and that it may even be a breach of the revised Helsinki code of 1975 on the use of human subjects in research. There is also some concern that the daily dose of folic acid being administered to one of the four groups in the MRC study is, at 4 milligrams per day, ten times that used in earlier work.

Recruits to the study, who must first declare themselves to their personal physicians, include only women who have already given birth to a child with spina bifida or encephaly and among whom the chance of a recurring defect is, at 3 per cent, comparatively high. MRC insists that the anxieties of protesters such as the National Childbirth Trust at the ethical basis of the trial are answered by its information leaflet for participants, which says that the consent of the woman's husband will normally be required and that women's medical care will not be diminished if they do not volunteer.

So far, 18 of the 132 recruits to the study have become pregnant (and one has produced a normal child). Whether the target number of 2,000 recruits will be found within five years is at this stage by no means certain. **Judith Abel**

Artificial reproduction

Unrestrictive guidelines for UK

THE Warnock Committee's recommendations to the UK Department of Health on artificial reproduction began accurately to leak out last week. The main conclusions of the 18-month study, due to be published at the end of June, are that commercial surrogate motherhood agencies should be banned; that hospitals and clinics specializing in *in vitro* fertilization (IVF) and artificial insemination by donor (AID) should be licensed and required to register successful births; that the children born through AID programmes should be legitimized; and that research on embryos should be limited to 14 days after fertilization.

To administer these provisions, the committee recommends a permanent national licensing body whose role would also include monitoring embryonic research and advising government on new developments in artificial reproduction techniques.

On the issue of AID births (already accounting for at least 2,000 children in Britain each year), it has also been recommended that no sperm donor should be allowed to father more than ten children and that his identity should remain undisclosed; it is not yet clear, however, what subsequent access a child conceived by the AID method would have to information about his or her natural father.

The broad conclusions are not, however, unanimous. Two of the 16 members of the committee hold that surrogate motherhood should not be completely banned, but accessible only when there is no other option for a childless couple. The dissenters advocate that, in these circumstances, arrangements should be undertaken by non-profit-making bodies such as adoption and fostering agencies; the British Agency for Adoption and Fostering is not, however, enthusiastic about the suggestion.

On embryo research, two further minority reports (signed respectively by 3 and 4 members of the committee) are expected; one opposes on principle all research on human embryos, the other argues against the special creation of embryos for research purposes.

First indications are that the committee's report will be fairly well received by physicians and researchers, although some claim that the 14-day limit on work with embryos is too restrictive. (The Royal College of Obstetricians and Gynaecologists has recommended a 17-day limit.) The committee also eschewed a time limit on how long embryos can be kept frozen where parents desire several children, although the general specification is that it should be long enough to allow for children to be well spaced. Parents should be consulted on the fate of spare embryos, the committee says.

The leaking of the Warnock Committee's recommendations has been greeted with relief both by researchers fearing restrictive regulations and by those who see a need for swift legislation, especially with increasing commercial interest in surrogate motherhood.

Despite the sense of urgency in the scientific community and, indeed, among the Warnock Committee members, government legislation is not likely before October 1985. But there is likely to be mounting pressure on politicians to achieve some form of legal guidelines well before then, especially once the report is published, later this summer. **Judith Abel**

British universities

Another turn of the screw

WHILE British universities contemplate the news that their recurrent grant is likely to fall in value by more than 2 per cent over each of the next 2 years, six of them have been named as guinea pigs for a study of university efficiency being undertaken by the Committee of Vice-Chancellors and Principals (CVCP) and the University Grants Committee. The chosen six are the Universities of Edinburgh, Essex, London (University College), Loughborough, Nottingham and Sheffield. These institutions will during the coming autumn collaborate in efficiency studies with a steering committee under Sir Alex Jarratt.

Although universities have been anxious to appear willing to cooperate in such efficiency exercises, their temper has not been improved by recent estimates circulated by CVCP which indicate that the recurrent grant is likely to fall in value by 4.4 per cent between the present financial year and 1986–87. The estimates are based on "indications" provided by the University Grants Committee and were arrived at by excluding the protected Information Technology and New Blood schemes and then incorporating government expectations for inflation over the next 2 years.

CVCP's document, circulated to vice-chancellors at the beginning of this month, argues pointedly that provisional levels of recurrent grant incorporate two levels of reduction in value: scheduled cash increases are lower than projected cost increases, and the cost increases are themselves lower than government expectations for inflation. The cash value of the recurrent grant is expected to rise from its current level of £1,249 million to only £1,320 million in 1986–87.

Mr Michael Baatz, secretary of the efficiency study group, emphasizes that the initiative for efficiency studies came from CVCP itself, albeit "in response to government interest". All British universities had declared themselves willing to take part, but the chosen six represent a variety of university types, old and new, large and small. The study is supported by a grant of £300,000 from the Department of Education and Science.

The plan for the study now agreed is unusual in at least two respects. Eight topics have been drawn up as suitable for investigation, ranging from the all-embracing ("financial management") to the particular ("animal houses"). But only one topic will be investigated at each of the six universities included in the study (the topic to be chosen jointly by the university and the committee), and so at least two of the possible topics will be left untouched. And the committee is pledged to make no judgement on academic matters, such as what subjects should be taught.

Mr Baatz admits that there will be much discussion on what constitutes an "academic" matter. While questions such as level of provision for each subject are clearly out of bounds, the committee will hope to make recommendations on how resources might best be deployed to achieve stated aims. The academic side of these questions is being tackled by a separate CVCP working group on academic standards chaired by Professor Philip Reynolds, vice-chancellor of the University of Lancaster. **Tim Beardsley**

Reagan's Lysenkoism

US PRESIDENT Ronald Reagan should be awarded a special "Lysenko prize" for his "star wars" theories, Academician Evgenii Velikhov asserted last week. Velikhov, a vice-president of the Soviet Academy of Sciences and chairman of the Committee of Soviet Scientists for Peace and Against Nuclear Wars, was speaking on Moscow Radio's "English for North America" service.

According to Velikhov, Reagan's allusion to "new defensive systems" that would give the United States an antimissile capability was simply "Lysenkoism". Present-day lasers, he said, would have to be improved by ten million times to provide a reliable antimissile defence system. Like Lysenko, he says, Reagan is prepared to "put science into storage" if it gets in the way of his theories.

The hope of "protecting all people" is a "wonderful concept", but, like Lysenko's agricultural theories, is in reality "a lie" which cannot be implemented.

Velikhov says he made this clear during a visit to the United States last month, in meetings with the Federation of American Scientists, the US National Academy of Sciences and "people with political and military experience". Vera Rich

Baikal-Amur railway

Building too fast for efficiency

SOVIET plans to complete construction of the Baikal–Amur Mainline (BAM) railway by autumn 1984, a year ahead of schedule, have been jeopardized by a lack of understanding of the geology of permafrost. This year, the Soviet media have noted several instances where the rapid exploitation of geological research findings for the good of the economy, urged by successive five-year plans, has run into difficulties. Oil extraction from newly discovered fields in Siberia is far behind schedule, and it was revealed last month that the reservoir of the Cheboksary hydro-electric station on the Volga had caused an unexpected rise in the water-table between Cheboksary and Gor'kii, so that the water-table in Gor'kii has already risen to ground-floor level in some places.

Such problems seem endemic in a centrally planned system. Civil engineering works may be started without allowing sufficient time for preliminary surveys; and if one sector carries out a programme of "shock-work", others working at normal speed will appear to be lagging.

The trouble on BAM appears to be a result of the decision to bring forward the construction date, so that the last "golden link" could be laid to celebrate Revolution Day (7 November) this year. BAM, which has been hailed as one of the most important achievements of Soviet civil engineering, has been built in sections, and the running of trains on completed portions has already earned, its publicists claim, impressive sums from the Soviet economy. Looping far to the north of the (Tsarist-built) Trans-Siberian Railway, and thereby avoiding sensitive areas close to the Chinese border, BAM, when completed, is expected to offer fast and com-petitive freight rates for the container transport of goods from the Far East to Western Europe. The driving of the final link is therefore economically important.

The course of BAM was carefully planned — according to official reports — by a think-tank covering all the relevant scientific disciplines. The chief snag on the final choice of route was the Kodar range of mountains, through which a 2-km tunnel had to be drilled at an altitude of 3,000 m. When the completion date was brought forward, it became necessary to complete this tunnel by May 1984 (leaving six months for the track-layers to do their work), and the tunnellers forged ahead with such gusto that by 15 February, they had already excavated 1,600 m of tunnel.

Unfortunately, however, the concrete workers responsible for facing the newly dug surfaces made slower progress, and before they could catch up, lumps of rock began breaking away from the unfaced ceiling of the tunnel. It was eventually decided to reinforce the roof with metal structures, but this remedy was adopted too late to prevent a serious cave-in.

Serious recriminations have broken out as to who was responsible for the cave-in. The tunnellers blame everything on the "mysteries" of the permafrost. They have hinted, moreover, that the strata encountered were less hard than the geologists had supposed, and that although temperatures were monitored in the excavated tunnel, readings were taken only at floor level, and it was only later discovered that temperatures near the roof were considerably higher (around 12°C). The chief directorate for the BAM construction, however, tends to blame "sluggishness" in the concreting of the roof, while admitting that an elementary law of physics had been ignored — that at the temperatures that built up in the tunnel, permafrost gradually ceases to be permanent.

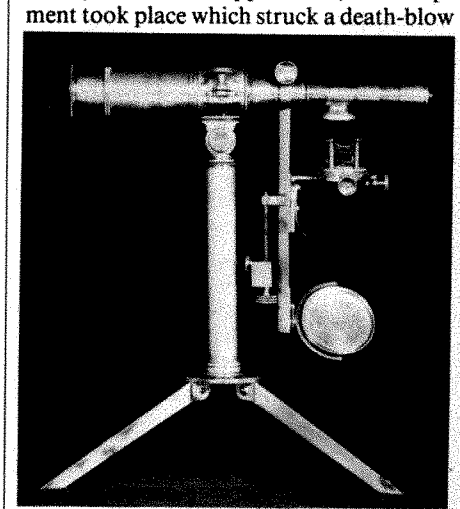
All the resources of Soviet society have now been mobilized: representatives of the Party bureau have been posted to "key sectors" and the concreting teams reinforced with Party cadres. The Ministry of Transport Construction has instructed the tunnellers to have the tunnel ready for traffic this autumn. The Chief Tunnel Construction Directorate, according to the Soviet newspaper *Sovetskaya Rossiya* considers this task "unrealistic". Officially, however, the schedule for driving the golden link remains unchanged.

Vera Rich

Optical microscopes

Reflector makes high price

A RARE reflecting microscope constructed in 1827 by John Cuthbert under the guidance of Dr Goring, the eminent Scottish microscopist, was sold last week in Sotheby's London sale-room for £8,000, about three times the price expected. The instrument was based on one produced several years earlier by the famous Italian experimenter Giovanni Amici, but instead of varying the magnification by a set of eyepieces, Cuthbert has provided a series of elliptical mirrors and Lieberkuhns. The mirrors are mounted in tubes to which the Lieberkuhns can be attached.



The reflecting microscope first made its appearance when the struggle for the achromatization of the microscope had almost been abandoned. Great strides had been made in the mechanical properties but there had been scarcely any improvement in the optical performance of the microscope since its invention two hundred years earlier.

Isaac Newton had certainly not helped matters by supporting the view that the construction of a colour-correcting achromatic lens system was not possible, and in 1672 he wrote to the secretary of the Royal Society outlining his ideas on how chromatic aberration could be overcome in a microscope by the use of a "reflecting piece of metal instead of an object glass".

Newton's preoccupation with a reflecting rather than with a lens system was influenced by his conclusion that refraction is always accompanied by dispersion, an unfortunate conclusion which went unquestioned for many years and which resulted in considerable delay before serious research was undertaken on the achromatic lens. As to Newton's microscope, if he ever had plans for its construction, they appear not to have materialized.

The first satisfactory reflecting microscopes made their appearance some 50 years later, and were by the Italian and London makers, Amici and Cuthbert. John Quekett, in his microscope treatise of 1848, points out the difficulties of making and using these instruments, but of the Cuthbert microscope, he says that it was (in its time) "the most perfect instrument manufactured in this country".

The success of Cuthbert's microscope was, however, short-lived. In 1830, just three years after its appearance, a development took place which struck a death-blow

The Cuthbert reflecting microscope

to all reflecting microscopes: the successful production of the long-awaited achromatic objective. For the first time, the conventional compound microscope began to emerge as an indispensable tool in science and industry. No longer was it merely a plaything for dilettante enthusiasts, who, to quote a nineteenth century historian, "regarded their costly instruments as precious toys rather than as tools for work and study".

Paradoxically the twentieth century has seen the re-emergence of reflecting systems for specialized use in ultraviolet or infrared regions of the spectrum; so even if Newton had been misled in his dispersion experiments, his pioneering work on the reflecting microscope was not altogether in vain.

Arthur Frank

Coronaries and diet

SIR — The article "You are not what you eat" (*Nature* **307**, 199; 1984) gives the seriously misleading impression that dietary modification cannot reduce the risk of coronary heart disease. In addition, the article contains many inaccuracies.

In the Coronary Primary Prevention Trial referred to in the article, all patients received a standardized diet which limited saturated fats and cholesterol and which was designed to lower blood cholesterol by 3–5 per cent. Both the treatment and the control groups achieved a 4 per cent plasma cholesterol reduction as a result. It is wrong to imply that the control group (no drug treatment) could not have done any better; controls showing a large dietary response were deliberately excluded. More restrictive diets have frequently been shown to reduce plasma cholesterol levels by 10–15 per cent.

You are incorrect in implying that only those in the study who reduced their plasma cholesterol to a level near the national average benefitted. Reduction of risk was directly and continuously related to the per cent reduction in cholesterol concentration. (You state that the group receiving the drug (treatment group) reduced plasma cholesterol by 17 per cent; the correct figure is 13.4 per cent. And you state that non-fatal myocardial infarctions were reduced by 17 per cent; the correct figure is 19 per cent.)

Although you did not distinguish between dietary cholesterol and dietary saturated fat, your article carries the clear implication that diet is unimportant in reducing the risk of coronary artery disease. The results of the trial clearly showed the benefit of lowering plasma cholesterol. In fact, it is almost standard practice for the patient to be treated with diet first, and a drug added only if diet fails to achieve a satisfactory reduction in plasma cholesterol. The results of the Oslo study, in which dietary modification and elimination of cigarette smoking achieved reduction in plasma cholesterol and a significant reduction in coronary artery disease, are consistent with the results of the Coronary Primary Prevention Trial and with our recommendation that patients with plasma cholesterol levels greater than 240 mg dl^{-1} should be carefully evaluated and should change their diet to reduce the level. Those whose plasma cholesterol remains elevated after a trial with diet are candidates for treatment with a drug. The suitability of this treatment must be an individual decision made by doctor and patient, based on accurate data on the patient's plasma lipoprotein levels. The trial indicates that vigorous treatment of this high-risk group will be effective if begun sufficiently early.

Unfair on Illmensee

SIR — Your coverage of what you call "the Illmensee affair" continues to prove unfair. Or has it become common usage in *Nature* to report on the failure of anonymous "other researchers" who unsuccessfully try to "repeat Illmensee's experiments", as you do in *Nature* **308**, p.394? Knowing Illmensee for more than sixteen years and having worked as one of his fellow PhD students in the same room for more than a year, I am fully convinced of his personal and scientific integrity. If others fail to repeat his work successfully — what of it? Even Carl Lewis has not yet reached Bob Beamon's 8.90 metres.

Indian items

SIR — Your news report (*Nature* **307**, 307; 1984) rightly terms recent exhortations of the head of India's University Grants Commission (UGC) as utopian, although the UGC chief is to be credited for highlighting maladies responsible for academic backwardness in Indian universities. The bureaucracy and the politicians have strangulated university autonomy. There is interference in day-to-day running of the academic administration, as witnessed only a few months back when the vice-chancellor of a university resigned in protest at a state political authority encroaching upon his stand to maintain discipline in the campus.

In India education is a state matter. Except with regard to research, technical and scientific education, the education is entirely within the purview of the states. For this reason education has not developed a national perspective, with each state going its own way. The first step to improve matters would be to bring education under the category of the concurrent list of the Indian Constitution. This will enable UGC to intervene effectively to protect academic interests.

In the Indian university system, a vice-chancellor has a very important role to play in shaping the academic life of a university. But the recent trend is to appoint vice-chancellors mainly on political grounds. So vice-chancellors have failed to inspire the respect that students and teachers should normally have for a person who is supposed to be the leader of academic life of a university. In this context I may mention the report of Justice Mootham in which the choice of vice-chancellors was dealt with at length. Similarly, the Radhakrishnan commission on university education has not only described the quality of a person to be chosen as a vice-chancellor but also prescribed a procedure for appointment of vice-chancellors. Let academic merit be the guiding principle in the selection of a vice-chancellor. Furthermore, the highest authority in the government should be directly accessible to the vice-chancellor with no bureaucrat acting as a middleman.

Much of the erosion of university autonomy is done in the name of finances. This has reduced universities to just another section of the Education Department of the State Secretariat. There is no justification in placing a provincial civil servant designated as Financial Officer controlling the university finances. Such an officer has only a narrow bureaucratic outlook and cannot apprehend the need and priority of the academic challenges. Let the university be allocated "*x*" finances and details of its disbursement or priority in expenditure be decided by the academic body itself.

Recent approval accorded to a scheme of promotion of university teachers by UGC is incongruous to the recent pronouncements of the UGC chief. Only recently UGC has approved automatic promotion from reader to professor and from lecturer to reader on the basis of length of service (13 years as lecturer and 10 years as reader) of an incumbent. This move was rejected by the Indian Science Congress (*Nature* **307**, 100; 1984), but it is a worrying trend. Promotion should depend on open competition based strictly on merit without any bias tied to the length of service.

Finally, I am certain a great deal of practical wisdom is contained in the reports of various education commissions set up by the Government of India in recent years. The reports of the Radhakrishnan, Mudaliar, Mootham, Sen and Kothari commissions are gathering dust on various governmental shelves. The UGC chief could render an invaluable service by implementing relevant recommendations from each one of these reports, which can be implemented at the UGC level. Such actions would strengthen moves to persuade government machinery to take effective measures to save universities from academic deprivation. Genuine concerted efforts could turn a demoralized academic community into a professional force committed to seek and advance frontiers of knowledge and able to contribute its fair share in stimulating intellectual growth, nationally and internationally.

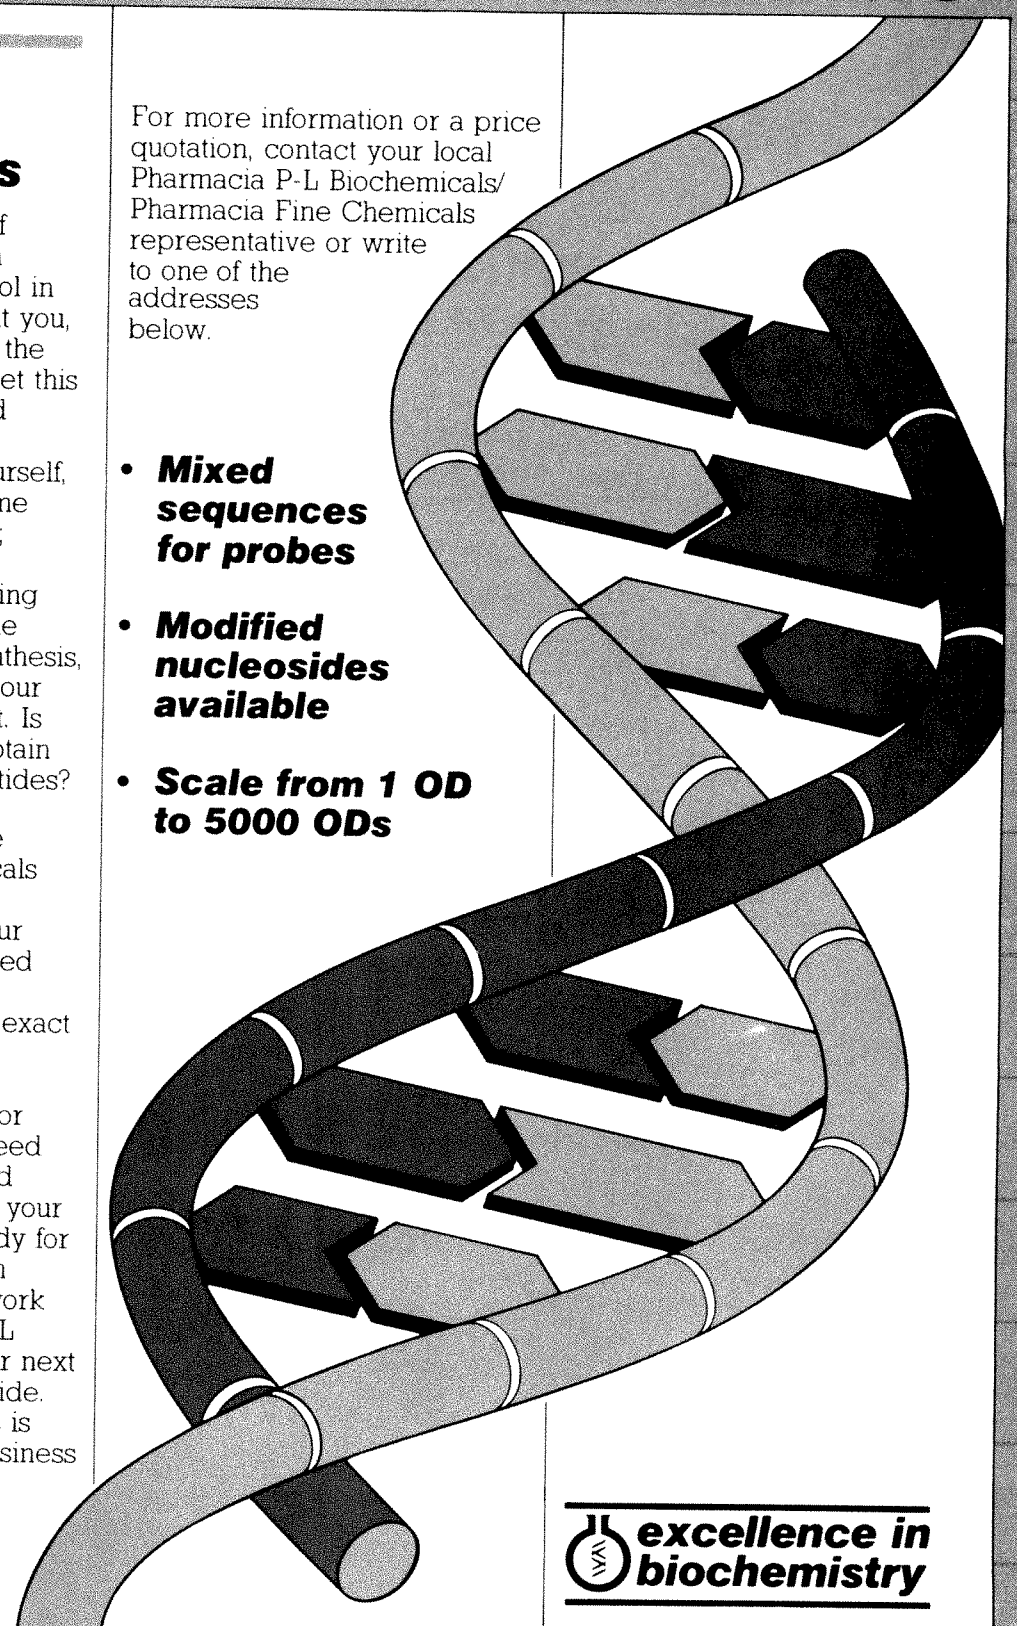
Custom Oligodeoxynucleotides From Pharmacia P-L Biochemicals



Make Discoveries, Not Reagents

Oligodeoxynucleotides of defined sequence are an increasingly important tool in research. This means that you, the researcher, must ask the question: "Where can I get this vital product?". You could synthesize and purify the oligodeoxynucleotide yourself, but this takes valuable time away from your research; instead of making new discoveries, you are making reagents! Expensive "gene machines" can do the synthesis, but you must still invest your time to purify the product. Is there no better way to obtain custom oligodeoxynucleotides?

The better way is to have Pharmacia P-L Biochemicals prepare your custom oligodeoxynucleotides. Our experienced team of skilled professionals can quickly synthesize and purify the exact sequence desired in the quantity that you require. Whether you need 1 OD or 5000 ODs, whether you need modified bases or a mixed sequence, we can supply your oligodeoxynucleotide ready for you to use. Put our custom synthesis experience to work for you—let Pharmacia P-L Biochemicals prepare your next custom oligodeoxynucleotide. Remember, your business is scientific research; our business is making your reagents.

For more information or a price quotation, contact your local Pharmacia P-L Biochemicals/ Pharmacia Fine Chemicals representative or write to one of the addresses below.

- ***Mixed sequences for probes***
- ***Modified nucleosides available***
- ***Scale from 1 OD to 5000 ODs***

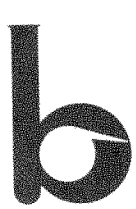
Materials for Peptide Synthesis from Bachem



We offer all the materials you need for a successful synthesis by both classical and solid phase techniques including:

* An extensive range of **resins** including **t-Boc** and **FMOC resin esters**
* **FMOC** amino acids including Arginine, Cysteine and Histidine derivatives
* Full ranges of **t-BOC, CBZ** and **NPS** protected amino acids

Delivery from stock, very competitive prices and consistent extremely high quality.

Custom Synthesis is our speciality

Perils of too much disclosure

The New England Journal of Medicine *would have authors disclose commercial interests in their articles. The American Institute of Physics will tolerate prior disclosure. Why?*

WALL Street in the past year has been seriously damaged not by the unpredictability of the markets (from which it usually manages to profit) but in its reputation. A few months ago, it was alleged that an employee of the *Wall Street Journal*, a newspaper highly respected by the financial community, had been helping his friends to play the markets armed with the knowledge of what was about to appear in print.

Soon afterwards, an Arizona academic appeared on a television network, bad-mouthing G.D. Searle's new synthetic sweetener — and afterwards confessed that he had been selling Searle stock short in the expectation that its price would fall (which, surprisingly, it did not). Both tales are illustrations of what Wall Street and the other financial markets call "insider trading" — the exploitation of private knowledge by a few favoured people to make profits out of the ignorance of others. Their peculiar difficulty is that, in each case, the culprits are people not strictly subject to the regulations that govern the behaviour of recognized market makers.

For the financial markets and for governments, it has become a kind of nightmare to know how outsiders with inside knowledge should be prevented from cheating others. The agony seems now to have afflicted the *New England Journal of Medicine*, if anything even more highly respected than the *Wall Street Journal*. (At least, it does not fire off unsubstantiated charges that the Soviet Union is using genetic manipulation to manufacture biological weapons, as the *Wall Street Journal*, on the basis of a flimsy knowledge of what a gene is like, has recently been doing.) Last month, the *New England Journal*, in an article by its editor Dr Arnold J. Relman, raised the question whether the commercialization of medical research has not now become so "rampant" that those who publish scientific articles in the technical literature, but who also have interests in commercial companies, may suffer intolerable conflicts of interest (*New Engl. J. Med.* **310**, 1182; 1984).

The question is interesting and important. That biomedical research has become uncomfortably commercial is widely accepted, even by some of those who hold this to be unavoidable or even desirable, for the sake of the rapid development of a new technology. That the publication of scientific articles can sometimes affect the prices of particular stocks is also undisputed; the most obvious effects are those which follow the appearance of disappointing (negative) reports of trials with new drugs, but the phenomenon is not new. So how can journals ensure that they are not being misused by their contributors?

The *New England Journal's* suggestion, now opened for public discussion before being implemented as editorial policy, is that all contributors should declare direct commercial interests within what they seek to publish. An employee of, or one who has been helped financially by, an interested company should say so openly, but researchers who act as consultants for a company should make a declaration to the editor, who may afterwards ask that some of this information should be disclosed. On the face of things, this sounds sensible enough, entirely consistent with the contemporary fashion for publishing one's latest tax return before running for public office. But is the procedure necessary? And would it deal with the problem identified?

Especially since the latest surge of interest in biotechnology, most journals have found that full-fledged companies active in the field have been eager that their employees should clearly acknowledge who pays their salary. The declared motive is that the companies shall be better placed to recruit in the science labour market, but no doubt it helps on Wall Street that potential stockholders know the company is not asleep. The *New England Journal's* remedy would not change this state of affairs, but reinforce it. Practice suggests, however, that fast-moving corporations rely more on secrecy than on patent protection, with the result that the publication of important research is often delayed and, then, muffled.

In this climate, the most likely conflicts of interest are not those of contributors turned inside-traders but the following: members of the editorial staffs of journals may improperly use what they know about material not yet published, while contributors may tell lies in the interests of some secret sponsor. Fortunately, most journals are all too well aware of the dangers of even minor unauthorized disclosures. (*Nature* is still bruised by the angry withdrawal of an important article through the innocent transmittal of the report of a referee whose interpretation of the data was more interesting than the author's.) But the opportunities for financial gain are novel, and should be inhibited.

Contributors who may be tempted to shade the truth for hidden reasons are potentially a more serious problem. The *New England Journal's* recipe would help if only it could be enforced. The trouble is that those who may be the most tempted are the least likely voluntarily to disclose their interests. And the ultimate deterrent will be what it has always been — that those who shade the truth are eventually found out, and then damaged in reputation more seriously than their pockets can have benefited.

So, for the time being, *Nature* will not be following the policy with which the *New England Journal* is flirting, believing that present practices are most often sufficient to guard against abuse — and that the exceptions are those least easily dealt with by formal rules. Nor, for that matter, will *Nature* be following the new editorial policy announced by the American Physical Society (see *Physical Review Letters*, 11 June). On a quite different issue, that of the prior disclosure of the content of a scientific article, the society now says that it will not in future regard prior publication of the substance of an article in popular newspapers or magazines "with large circulations outside the physics community" as a bar to publication in its journals. It is shocking that this announcement should appear in the journal which, in the late Professor S.A. Goudsmit's time, most stoutly resisted the preference of many physicists for unrefereed publication on the front page of the *New York Times*.

The American Physical Society clearly does not appreciate what trouble this ill-thought policy will cause. Perhaps physicists are by now so dependent on the pernicious preprint system that they think their journals are archival from the start. But this new recipe is as neat a device as there could be for ensuring that important work is misrepresented to the public — one newspaper may sensationalize a hearsay account, the others will ignore the event for fear of seeming scooped. Even in the scientific press, broken embargoes may have the same disastrous consequences. This, in retrospect, is what may be made of the pallid account, in a recent issue of the journal *Science* (reference withheld), of a group of papers to be published in *Cell* and *Nature* in the next few weeks, and which may be the most important discovery so far this year. Thus will other tales of discovery be half-told if the American Institute of Physics is followed.

Cardiac peptides and the control of sodium excretion

from G. A. Sagnella and G. A. MacGregor

PHYSIOLOGICAL experiments have repeatedly suggested the existence of natriuretic substances that increase the excretion of sodium from the kidney, probably by inhibiting the reabsorption of sodium along the renal tubule[1]. These factors are of particular interest partly because the amount of sodium in the body's extracellular fluid regulates its volume, and partly because of suggestive evidence of a link between the kidney's ability to excrete sodium and essential hypertension[1], a major risk factor for cardiovascular disease[2].

It has recently become clear that there are at least two distinct types of natriuretic substances. One, probably produced by the hypothalamic region of the brain, is an inhibitor of ($Na^+ + K^+$) ATPase, the enzyme which transports sodium across membranes, and might be a contributory factor to a rise in blood pressure[1]. The other, comprising peptides that have been isolated from the atria of the heart, has recently become the focus of attention for numerous laboratories throughout the world, although its physiological significance remains tantalizingly uncertain. The occasion for the sudden attention to the atrial peptides is their recent characterization and synthesis; moreover, as described on pages 717 to 726 of this issue of *Nature*, their precursor has now been identified and its sequence deduced.

Both neuronal and humoral mechanisms have been suggested[3] for the increase in urinary outflow that follows stimulation of atrial 'stretch' receptors[4]. Speculation that a novel endocrine system might be involved was stimulated by the observation that intravenous injection of rats with atrial, but not ventricular, extracts led to a striking natriuretic and diuretic response[5]. Moreover, the natriuretic activity is associated with endocrine-like secretory granules of the atrial cells[6,7], and the number of granules changes during water deprivation[8].

Early work suggested that the active material was a peptide[9-12] and, more recently, it was shown to be a mixture of peptides of different molecular sizes which are not only natriuretic but can also relax the smooth muscle of vascular tissue[13], causing vasodilation. A number of peptides — variously named atriopeptins, auriculins, cardionatrins and atrial natriuretic factors — have recently been purified and sequenced[14-20]; their structures are summarized in Fig.1. There are two striking conclusions. First, all the rat peptides seem to be derived from a common precursor, as suggested by earlier indirect evidence[9-12] and consistent with the isolation of a 73 amino acid peptide containing the atrial natriuretic sequence in its carboxy-terminal region[21]. Second, the one human peptide so far sequenced differs from the rat peptide by only one amino acid. All the peptides require an intact disulphide bridge for biological activity.

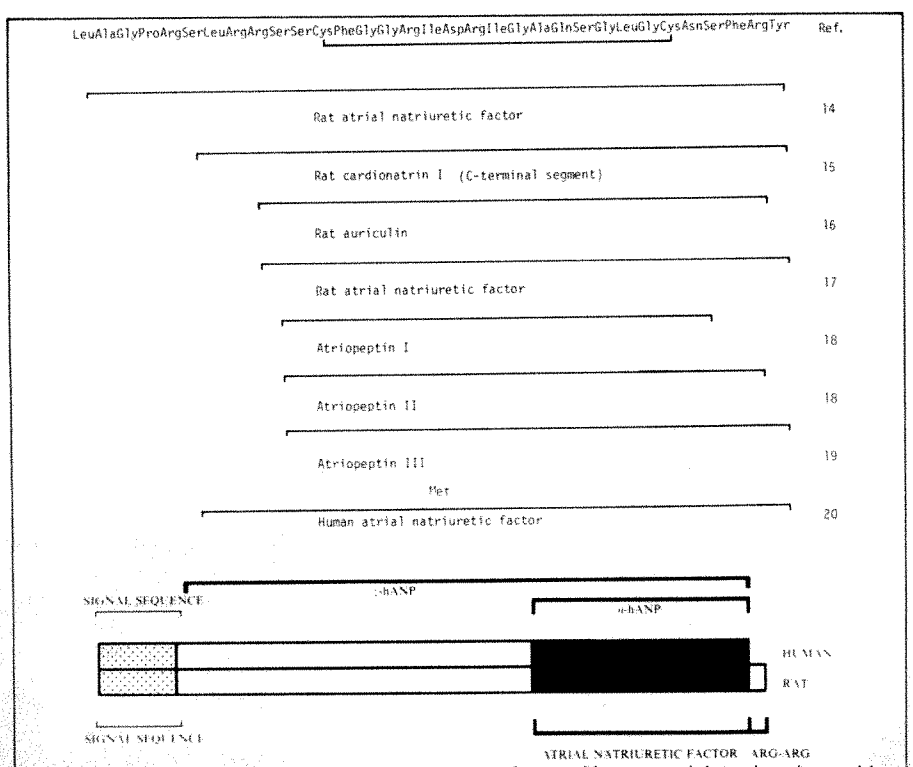

Fig.1 Amino acid sequences and proposed names of rat and human atrial natriuretic peptides (above) and organization of their precursors (below).

The suggestion of a common precursor for the peptides is now borne out by the sequences of precursor cDNAs of both rat and human atrial peptides reported by three groups in this issue of *Nature*. Both Yamanaka *et al.*[22] and Maki *et al.*[23] have cloned cDNA of the atrial natriuretic factor derived from rat atrial mRNA, and have determined its nucleotide sequence and deduced an amino acid sequence. The precursor is 152 amino acids long and contains in its carboxy-terminal region the amino acid sequences of all the atrial peptides reported to date (Fig.1). It also contains a likely signal sequence with a high content of hydrophobic amino acids in the N-terminal region, which is a characteristic feature of precursors of secretory proteins[24]. A remarkably similar sequence is reported by Oikawa *et al.*[25] for the cDNA encoding a precursor of the human atrial natriuretic peptide. (The deduced sequence contains not only the human atrial natriuretic peptide α-hANP, but also γ-hANP, a 126 amino acid peptide with the α-hANP sequence at its carboxy-terminus and which Oikawa *et al.* have identified in human atrial tissue — see Fig.1). Like the rat precursor, the human precursor contains a putative signal peptide sequence at its amino-terminus. There are some differences however — in particular, the Arg-Arg dipeptide following the atrial peptide sequence in the rat precursor is lacking in the human molecule. This may reflect differences in post-translational activation mechanisms.

The physiological function and importance of the atrial peptides have yet to be defined. Clearly, the fact that they have potent natriuretic and diuretic actions on the kidney as well as a vasodilatory effect raises the possibility of a role in the regulation of body fluids and blood pressure. Moreover, the peptides antagonize the vasopressor actions of the hormones noradrenaline[17] and angiotensin II[16]. Although limited, the available evidence is compatible with a hypothetical scheme in which an increase in extracellular fluid volume may serve as a trigger for release of atrial peptides into the general circulation (Fig.2); obviously, a number of questions remain to be answered.

How these peptides relax vascular smooth muscle and increase sodium excretion is not yet clear. They do not seem to act by inhibiting the ($Na^+ + K^+$)ATPase[12], and there is conflicting evidence as to their effect on the glomerular filtration rate — atrial extracts have no marked effect on it[26], whereas synthetic atrial natriuretic factor increases it slightly[16]. Atlas *et al.* suggest that the natriuretic effect results from the vasodilatory action of the peptide and a shift of blood flow to the medullary region of the kidney[16].

The characterization of the peptides at

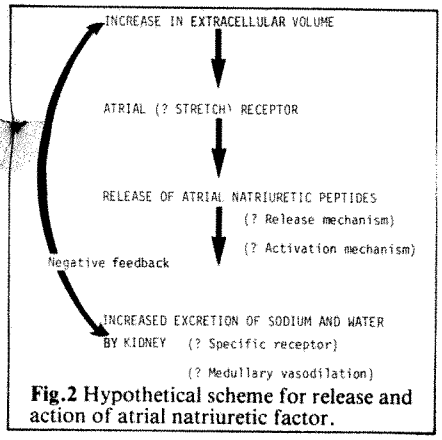

Fig.2 Hypothetical scheme for release and action of atrial natriuretic factor.

the molecular level and their subsequent synthesis provides a basis to investigate their mechanisms of action at the physiological and biochemical levels. There will undoubtedly be rapid progress in establishing radioimmunoassays to detect the presence of the peptides in the circulation and, if they are present, to test whether the circulating levels change with alteration of extracellular volume.

Clearly the potential roles of the peptides in disorders of electrolyte balance and in blood-pressure regulation remain to be clarified. For example, might Bartter's syndrome reflect excess atrial natriuretic factor and might hyporeninaemic-hypoaldosteronism be associated with a lack of it?

Finally, the relation of the atrial natriuretic peptides to other postulated, but as yet uncharacterized, natriuretic agents remains to be clarified. Teleologically, the existence of two natriuretic substances, one with vasopressor and the other with vasorelaxant properties, could allow the integrated control of both electrolyte and blood pressure homeostasis. □

Optical physics

Generation of the shortest ever optical pulses

from Peter Knight

How many optical cycles do you need in a pulse for it still to be called a light wave? Ippen, Fujimoto and Weiner at MIT have just reported the generation and measurement of 16 femtosecond (1.6×10^{-14}s) optical pulses of centre wavelength 620 nm which contain just eight optical cycles (*Appl. Phys. Lett.* **44**, 832; 1984). They also report that they can see the colour of the light change as their high-repetition-rate laser apparatus compresses the optical pulses. These are the shortest light pulses ever generated and, since a molecule takes about 10 fs to vibrate, they open a new time-window in the study of ultrafast processes.

The generation of picosecond optical pulses has become fairly straightforward with the use of laser mode-locking. Because laser action is encouraged over as wide a frequency band as possible, many laser modes will oscillate at once. Mode-locking gives each mode a common phase so that constructive and destructive interference among the different waves leads to a regular train of pulses. Each of these pulses has a temporal width inversely proportional to the number of modes participating and thus to the laser gain bandwidth. For this reason a dye laser which can be excited over a wide frequency range can generate extremely short pulses. For example, a colliding-pulse ring geometry, developed at Bell Labs and now used by Ippen *et al.*, can generate reliable pulses of less than 100 fs duration.

The study of ultrafast phenomena requires even these short pulses to be further compressed in time. To achieve that degree of compression, Ippen *et al.* at MIT (and other groups in Bell Labs, IBM and Rochester) have stretched out the pulse frequency spectrum even more by 'chirping' the light so that the carrier frequency is swept. When this is followed by a dispersive element, the blue-shifted training edge catches up with the red-shifted leading edge and compresses the pulse.

Chirping can be produced by the nonlinear propagation of intense laser light in a liquid such as carbon disulphide. The intensity-dependent alterations in the refractive index of the liquid cause self-phase-modulation of the light. This method, proposed by Giordmaine at Bell Labs, has proved troublesome. The optical pulses can be chirped, but not in a reproducible or stable manner.

Nonlinear opticians have turned to single-mode glass fibres to produce stable uniform chirping. Light from a mode-locked laser can be focused into the small-diameter (about 10^{-3} cm) core of the fibre to give internal intensities large enough for nonlinear effects to be important. The nonlinear refractive index produces a phase-shift which depends on the instantaneous intensity. The variable phase-shift increases until the peak of the pulse arrives and then it diminishes. The instantaneous frequency shift is given by the time-derivative of the phase shift, so that frequencies in the leading part of the pulse are lowered while those in the training edge are raised. The size of this frequency chirp increases directly with the length of the fibre. This chirping, combined with dispersion in the fibre, is the basis of the 'soliton laser' developed by Mollenauer and Stolen at Bell Labs (*Opt. Lett.* **9**, 13; 1984). The spectrally stretched pulse, on emerging from the glass fibre, can be compressed in time using a dispersive grating pair technique which allows the blue-shifted trailing edge of the optical pulse to catch up with the red-shifted leading edge.

Ippen's new experiment uses a colliding-pulse, mode-locked, dye laser to produce a train of pulses each of 65 fs duration. Single pulses are selected and amplified to initial energies of 5 μJ with a repetition rate of 10 Hz, and then spatially filtered, collimated and focused into an 8 mm long polarization-preserving fibre, which broadens the spectrum of pulse by a factor of about four by nonlinear chirping. This is followed by a grating pair to compress the pulse to its final length of eight optical cycles. The pulses are detected by a second-harmonic auto-correlator which determines temporal length by measuring the spatial extent of the pulse of light.

In a femtosecond, light travels one-third of a micrometre, so femtosecond pulses can be used to study a whole range of ultrafast processes which, until now, have been unresolvable. In condensed matter physics, such pulses can be used to study transport processes in semiconductors, non-radiative relaxation, and molecular vibration and re-orientation. In photobiology and photochemistry, direct observations should be possible of energy dissipation, transport and dephasing. The generation of femtosecond pulses has stretched nonlinear optics to the limit. With only eight cycles left in a pulse of visible light, any improvement would seem to demand a shift to the ultraviolet. Meanwhile, the new results of Ippen *et al.* will be eagerly applied to a wide range of transient phenomena. □

Microbiology

Proteins that bind the β-lactam antibiotics

from A.F.W. Coulson

A MEETING that is concerned more with the enzymes that form the targets for the β-lactam antibiotics than with the β-lactamases that destroy them, would not sensibly be called a 'β-lactamase workshop'. But the name was coined in 1975 for the first of the workshops; by the third*, held recently, the focus had changed.

The target enzymes can be identified in whole cells by their binding to ^{14}C-penicillin G. In *Escherichia coli* there are two classes of penicillin-binding protein (PBP). The low-molecular-weight proteins, PBP-4, -5 and -6, are not essential to the organism, are DD-carboxypeptidases and are believed to regulate the degree of cross-linking of the cell wall. The high-molecular-weight PBP-1a, -1b, -2 and -3 have already been shown to be essential to *E. coli*; real progress in understanding the behaviour of these membrane-bound proteins is now becoming possible through the cloning and sequencing of their genes.

The sequence of the PBP-3 gene, representing a protein of 588 amino acids, was reported a year ago by Y. Hirota (National Institute of Genetics, Mishima). PBP-3 displays both transpeptidase and transglycosylase activities, and the latter is not inhibited by penicillins. B. Spratt (University of Sussex) presented evidence that the transpeptidase activity is associated with the carboxy-terminal half of the molecule, whereas the amino-terminal half contains the transglycosylase activity.

J. Broome-Smith (University of Sussex) has sequenced the genes for PBP-1A, PBP-1B and PBP-5. 1A and 1B are highly homologous; otherwise the only extensive sequence similarities in this group occur in the region of the tetrapeptide -Ser-X1-X2-Lys-. Tetrapeptides of the same form also occur in low-molecular-weight DD-carboxypeptidases and in several examples of each of two types of β-lactamase. For β-lactamase it has been very thoroughly established that the serine residue is part of the active site, and is acylated by a β-lactam in the course of its hydrolysis. Other similarities in the sequences of these three groups of enzymes are also concentrated in the neighbourhood of the tetrapeptide sequence. It is clearly very tempting to suppose both that the serine residue is part of an active site with a similar role in the mechanisms of all the enzymes, and that all the genes are homologous, at least in parts.

A highlight of the meeting was the presentation of the first high-resolution X-ray crystal structure of one of the proteins that interact with penicillins: the 2.8Å structure of a *Streptomyces* DD-carboxypeptidase (J. Kelly, University of Connecticut). The enzyme contains two regions of secondary structure — a six-strand β-sheet and a group of five stacked α-helices. To add to the progress that has been made in the last four years in extending the sequence-based classification of β-lactamases, R. Ambler (University of Edinburgh) reported a partial sequence of the Zn-containing β-II enzyme from *Bacillus cereus*, still the only member of class B. And J.O. Lampen (Rutgers University) presented a partial sequence of its gene.

The most interesting mechanistic study was that described by R.F. Pratt (Weslyan University, Connecticut) who showed that acyclic esters of the form $Ar.CH_2.CO.NH.CH_2.CO_2R$ are hydrolysed by β-lactamases — the first non-β-lactam substrates to be discovered. Transpeptidation can occur from these substrates to suitable amines, which implies that acyclic amides must also be substrates (J.R. Knowles, Harvard University).

The induction of penicillinase in bacilli has unusual features which have made it a long-standing problem, a solution to which may be at hand now that clones of the entire penicillinase operons are available (Lampen). It seems clear that the main oddities in the induction arise because the inducer modifies the cell wall giving rise to a 'second messenger' within the cell; the genetic control itself may be entirely conventional. The nature of the modification to the cell wall remains mysterious, particularly since it can be brought about by a variety of chemically very different agents.

Astronomy

Quadrantid meteors

from David W. Hughes

IT is none too easy to gather data on the Quadrantid meteoroid stream. January 3 or 4, depending on our phase in the leap-year cycle, is the only day of the year on which the Earth intersects the stream; the point on the celestial sphere from which the shooting stars appear to originate has a declination of + 48.5°, so Quadrantids are best seen from high latitudes in the Northern Hemisphere where winter makes visual and photographic conditions seldom satisfactory; and at least one year in four is hampered by moonlight. Moreover, the Quadrantid stream is very narrow, the time between half-maximum flux rates being about 12 hours, and if the maximum occurs when the radiant is low in the sky, the proportion of the flux that can be observed by any method is much reduced. This factor limits optimum observations of the shower to one year in every four.

Radar methods can overcome two of the problems, permitting the observation of meteors in daylight and through clouds. They, however, suffer from their own kind of 'bad weather', because radio propagation conditions in the ionosphere can vary considerably as a function of solar cycle. Another problem with radar is the identification of the shower meteors. This is usually accomplished simply by subtracting an assumed background rate from the total observed rate.

One goal of meteor stream investigations is to unravel the disintegration process of the parent comet and the subsequent evolution of the meteoroid stream. A knowledge of the particle number density across the stream and around the stream orbit, and the way both of these vary as a function of particle size, would be very useful in that context. Hence the value of the determination by B.A. McIntosh, of the Herzberg Institute of Astrophysics, Ottawa, Canada, and M. Šimek, of the Astronomical Institute, Ondřejov, Czechoslovakia, of the long-term average cross-section of the Quadrantid meteoroid stream by analysing radar data obtained over nearly a quarter of a century (*Bull. astr. Inst. Czechoslovakia 35*, 14; 1984).

The Ondřejov and Ottawa radars are both pulsed systems and are similar in operation. Typical parameters are pulse length 10 μs, peak power 25 kW, repetition frequency 500 Hz. The antenna is fixed at an elevation of 45° and meteors within a line-of-sight distance of 400 km are recorded. Meteors are sorted into three duration classes, equivalent to median magnitudes of + 6, + 1.6 and − 1.0.

The practice of adding one year's data to the next is common with Quadrantid researchers but McIntosh and Simek warn that it is not without problems. These become obvious when the combined data for the time interval 1958–81 are compared with the well-observed year of 1979. There are three basic numerical values which represent any flux curve: the time of maximum flux, the rate of rise and the rate of decay. The last two can be combined to give a stream width which is usually defined as the change of solar longitude that occurs during the time when the stream is more active than half its maximum activity. The

authors noticed that the stream width from the combined data was twice that of 1979. The cause, they say, is the variation in the position of maximum, which can change by as much as 0.5° in solar longitude from year to year. So the annulus of Quadrantid meteoroids in the Solar System is not perfectly elliptical and deviations from this ellipse, at the descending node, can be as much as 7×10^5 km.

Contrary to the findings of many researchers, McIntosh and Šimek found that the maximum flux of bright meteors did not inevitably occur after the maximum flux of faint ones; in certain years the bright meteors preceded the faint ones. For all three meteor magnitudes the rate of rise of the flux to the maximum was slower than the subsequent fall. It was found, however, that the asymmetry increased as one considered brighter meteors. The theory of meteor stream production predicts that width should decrease as a function of meteor brightness. The authors found that the + 6.0 and − 1.0 magnitude meteors obeyed this rule but that the + 1.6 magnitude meteors had a wider flux curve than either of the others.

In conclusion, it is clear that the Quadrantid shower, currently both one of the most active showers and the narrowest, has many peculiarities. These can, in the main, be blamed on Jupiter. The ascending node of the Quadrantid orbit occurs very close to Jupiter's orbit. Also the mean period of the Quadrantids is approximately half Jupiter's orbital period. This causes the nodes of the Quadrantid orbit to regress by about 0.4° per century, leading to mass sorting in the shower (smaller meteoroids usually peaking earlier than larger ones) and introducing short-term resonance fluctuations which again have a size-dependent effect.

Jovian perturbation is very selective. The small sector of the stream that is in the vicinity of Jupiter every 11.86 years will be shifted by larger amounts than the rest of the stream. The velocities of the perturbed meteoroids will be changed slightly and they will redistribute themselves around the orbit, eventually forming a low-density tail preceding the main body of the stream. McIntosh and Šimek conclude that the degree of asymmetry so produced is to some extent a measure of the age of the stream.

This leads us to one of the main unsolved questions concerning meteor streams. How old are they? We know that the Quadrantids are old enough for the meteoroids to have spread out fairly evenly around the orbit and for the parent comet to have completely disappeared. But the stream is still young enough to retain the record of slimness. If only we knew its age our ideas about stream evolution could be placed on a much firmer footing. □

Molecular biology

DNA gyrations in reverse

from James C. Wang

In the well-known double-helix structure of DNA, the two strands revolve around each other. The topological problem of separating the parental strands during replication, particularly when the double-stranded DNA is in the form of a ring and thus the complementary strands are two intertwined single-stranded rings, was recognized more than two decades ago[1,2]. The enzymes capable of solving such topological problems, DNA topoisomerases, are ubiquitous. They catalyse the transient breakage of the DNA backbone and the passage of DNA strands through the transient breaks[3-5] in two mechanistically distinct ways. The type I enzymes break and rejoin one strand at a time and catalyse the crossing of one strand through another; the type II enzymes break and rejoin a pair of strands in concert and catalyse the crossing of a double-stranded DNA segment through a double-stranded break. It is not surprising that both types of activities are found in an archaebacterium *Sulfolobus*, as reported by Kikuchi and Asai on page 677 of this issue of *Nature*; what is amazing, however, is that *Sulfolobus* also contains an entirely new subclass of type II topoisomerase[6].

Until now, two subclasses of type II topoisomerases had been found in eubacteria and eukaryotes. Bacterial gyrases, which fall into one subclass, are characterized by their ability to reduce the 'linking number' of a double-stranded DNA ring. The term 'linking number' is a topological quantity defined as the number of times one strand revolves around the other when the duplex ring is laid in a plane. If a DNA ring laid in a plane assumes the B-helical form, 10.5 base pairs make a complete helical turn and the linking number is the total number of base pairs divided by 10.5. When a duplex DNA ring is incubated with gyrase and ATP *in vitro*, the linking number is reduced by as much as 10 per cent below that of the most stable B-DNA structure. Gyrase achieves this energetically unfavourable reduction in linking number, termed 'negative supercoiling', by coupling DNA supercoiling to ATP hydrolysis.

The other subclass of type II topoisomerase includes those found in eukaryotes and phage T4 topoisomerase. These enzymes, though ATP-dependent, can only break and rejoin DNA to allow the passage of strands in such a way that the linking number of a duplex DNA ring 'relaxes' towards that of the most stable DNA structure, whatever its initial linking number; in this process, the chemical energy of ATP hydrolysis is not harvested by the DNA.

By contrast, the type II topoisomerase found by Kikuchi and Asai in *Sulfolobus* increases the linking number above that of the most stable DNA structure by coupling ATP hydrolysis to the positive supercoiling of DNA. 'Reverse gyrase', as Kikuchi and Asai call their enzyme, thus becomes the founder member of a third subclass of type II topoisomerase, and an unexpected one, because no positively supercoiled DNA has ever been isolated from cells in physiological conditions.

Since all three subclasses are ATP-dependent and catalyse the passage of one double-stranded DNA segment through another, their differences lie in the directionality of duplex cross-over. Strand passage catalysed by the gyrase and reverse gyrase is directional, though opposite in sign, whereas strand passage catalysed by the other subclass lacks directionality and the DNA relaxes into a thermodynamic valley.

The discovery of reverse gyrase raises a number of questions. First, is it a distinct enzyme rather than an altered form of a gyrase of the same organism that has somehow changed its direction of strand passage? Mechanistically, it is an intriguing question whether directionality can be altered by changing the quaternary structure of an enzyme or by modifying its subunits. The scanty information that is available comes from studies with *Escherichia coli* gyrase. In the absence of ATP, gyrase can relax negatively supercoiled but not positively supercoiled DNA. However, a complex containing the A subunit of gyrase and what is probably a proteolytic fragment of the B subunit of gyrase, can relax both negatively and positively supercoiled DNA[7,8]. Moreover, gyrase is stimulated to relax positively supercoiled DNA by the binding of the β,γ-imido-analogue of ATP[9]. Whereas such experiments show that it is possible to nullify the normal bias in the directionality of strand passage (relaxation of negatively supercoiled DNA) by the modification of a subunit of gyrase, it is more difficult to envision how strand passage could be switched from one direction to another by subunit modifications. The total lack of directionality in strand passage catalysed by phage T4 and eukaryotic type II topoisomerases is as intriguing as the directional strand passage catalysed by the other type II enzymes. In the case of the eukaryotic type II topoisomerases, the purified enzymes are homodimers. It is plausible that complexes between such enzymes and DNA have a twofold symmetry axis and that the symmetry abolishes any bias in the directionality of strand passage. The interesting question, then, is whether the binding of additional protein factors, or the

anchorage of the enzyme to a surface, can destroy such symmetry and make strand passage directional.

Is reverse gyrase unique to archaebacteria? Even with hindsight, there has been no hint of such an enzyme in eukaryotes. Interestingly, however, positively supercoiled plasmid DNA has been isolated from *E. coli* following inhibition of its gyrase by novobiocin or oxolinic acid, although this can be attributed to the formation of a complex between DNA and drug-inactivated gyrase molecules[10] — relaxation of a DNA when it is coiled around inactivated gyrase molecules is expected to increase its linking number[11]. Furthermore, DNA gyrase is overproduced in cells treated with gyrase inhibitors[12], which might explain the slow time course for the formation of positively supercoiled *E. coli* plasmid DNA following the addition of gyrase inhibitors[10]. The observation that *E. coli* plasmid DNA isolated from temperature-sensitive gyrase mutants at non-permissive temperature is not positively supercoiled[10,13,14] also argues against the existence of a reverse gyrase activity in *E. coli*. Nevertheless, the possibility of a reverse gyrase in eubacteria or eukaryotes cannot be discounted.

Why does *Sulfolobus* need a reverse gyrase in addition to its other topoisomerases? This is essentially the same question as why there are three topoisomerases in *E. coli*[15]. Whether some particular aspects of DNA in archaebacteria require a reverse gyrase is unknown; even the state of DNA supercoiling in such organisms remains to be determined.

If there is one philosophical point to be gleaned from the coexistence of supercoiling and relaxing topoisomerases, it appears to be that nature not only solves the topological problems that come with intertwining of strands in the double-helix structure of DNA, but also seems to take full advantage of the topological properties of supercoiled DNA. At least in eubacteria, there is strong evidence that intracellular DNA is negatively supercoiled, that the degree of unwinding influences many vital cellular processes including replication, transcription and certain site-specific recombinations[3-5], and that multiple topoisomerases are, perhaps, needed to regulate the degree (see ref.12 and refs therein). For eukaryotes, the first question is whether the evidence of their lacking supercoiling activity belies what actually occurs *in vivo*. Indirect evidence suggesting a supercoiled state in regions or subpopulations of intracellular DNA in eukaryotes has been accumulating (see, for example, refs 16–18). With the recent identification of the gene encoding yeast type II topoisomerase[19,20] and efforts of a number of laboratories in the search for other genes encoding eukaryotic DNA topoisomerases, powerful genetic tools can begin to complement the available biochemical approaches to answer this question. □

Metallurgy

'Heavy' electrons in metals

from Tony Leggett

THE electrons in a typical metal interact quite strongly with the static crystalline lattice, with the vibrations of this lattice (phonons) and with one another. Many properties of nonmagnetic metals seem to be rather well explained, however, by a simple model, based on Landau's model of a Fermi liquid, in which the effects of these interactions are summarized by saying that the electrons behave as if they had an effective mass, m^*, which is different from their true mass, m, and a residual mutual attraction or repulsion. For almost all metals known until recently, the effective mass ratio m^*/m lies in the range 0.1–10 and the inter-electron interactions are not particularly strong. Great interest therefore attended the discovery of a class of metals which appear to be described by a Fermi-liquid picture but which have effective mass ratios of the order of 200 and, probably, correspondingly strong effective interactions. The interest was much increased when it was found that some of the metals of this class become superconducting at low temperatures, and is certain to be further heightened by the recent discovery that at least one of them, U_2Zn_{17}, undergoes a magnetic phase transition (*Phys. Rev. Lett.* **52**, 1551; 1984).

The systems in question are all compounds of a rare-earth element (usually cerium) or an actinide element (usually uranium) with one or more other metals: the most striking are $CeAl_3$, $CeCuSi_2$, UBe_{13}, UPt_3 and U_2Zn_{17}. From an atomic point of view, what they have in common is that the Ce or U atoms supply f-electrons, which are fairly tightly bound to the atom and would therefore be expected, in the solid, either to be strictly localized or to form a very narrow band, while the lighter elements supply p- or d-electrons which should be much more loosely bound; it seems probable that the electron states near the Fermi surface, which are expected to dominate the experimental behaviour, include both types. Probably the most striking experimental property shared by all these compounds is their enormous, low-temperature, electronic specific heats (C_{el}): while C_{el} is to a first approximation proportional to T as in ordinary metals, the ratio is of the order of 1 J K^{-2} as against the usual value, ~ 1 mJ K^{-2}. If interpreted in the conventional Fermi-liquid picture, this yields effective masses of the order of 200 electron masses; correspondingly, the 'Fermi temperature' above which the electrons are no longer degenerate is of the order of 10 K, compared with ~ 10^4 K for conventional metals. Although this huge effective mass could conceivably be due simply to the extreme narrowness of the band formed by the atomic f-electrons (the p- and d-electrons probably have much smaller effective masses and so contribute little to the specific heat), it seems very probable that it also has large contributions from strong electron–electron interactions.

While many of the experimental properties of the various compounds at temperatures above about 10 K are qualitatively similar, their low-temperature behaviour is strikingly different. $CeAl_3$ appears to undergo no phase transition of any kind down to the lowest temperatures reached (~ 0.02 K); $CeCu_2Si_2$ has a superconducting transition which depends sensitively on such factors as preparation method and pressure; UBe_{13} and UPt_3 become superconducting at about 0.85 K and 0.54 K respectively; while, as the new paper shows, U_2Zn_{17} undergoes a phase transition at 9.7 K to what appears to be an antiferromagnetic state.

In trying to make sense of this bewildering variety of behaviour it is tempting to turn for guidance to the one extended laboratory system of fermions in which we know that inter-particle interactions are very important, namely liquid ^{3}He. Indeed, some experimental properties of the heavy-electron metals, particularly the specific heat at intermediate temperatures, show some striking similarities to those of ^{3}He. One important feature of the behaviour of ^{3}He that is often believed to be characteristic more generally of strongly interacting Fermi systems is the part played by long-lived spin fluctuations, which arise from the fact that the liquid is 'nearly ferromagnetic' (or 'nearly solid').

Interestingly, when liquid ^{3}He becomes superfluid (the analogue of the superconducting transition in metals) the Cooper pairs form not, as in ordinary superconductors, with total spin S and angular momentum L equal to zero, but with $L = S = 1$. As a result, ^{3}He becomes an 'anisotropic superfluid' and has many unique properties. If, therefore, spin fluctuations are equally important in some or all of the heavy-electron metals, then it is tempting to speculate that these systems might become the first known superconductors to form Cooper pairs like those in ^{3}He; that is, the first (genuinely) anisotropic superconductors.

In fact, some of the experimental properties of UPt_3 and UBe_{13} have already been interpreted as supporting this hypothesis; however, it may be some time before a really clear-cut demonstration one way or the other is available. In this situation, the discovery of an apparently antiferromagnetic phase transition in U_2Zn_{17} is particularly intriguing: it demonstrates clearly that magnetic interactions can be extremely important in heavy-electron metals, yet simultaneously indicates that in this case at least they are not, *prima facie*, of the kind that is likely to give rise to anisotropic superconductivity. Clearly we have a lot to learn about the subtle interplay of interactions in these fascinating systems. □

WORK-MEASURING MACHINES

UNDER this title a little *brochure* has recently appeared from the pen of the Rev. F. J. Smith, B.A., of Taunton, in which work-measuring dynamometers, or *ergometers*, of various forms are described. Amongst these machines there are many devised by the author himself, and some of these are of considerable interest and much originality.

The leading feature of this instrument is the position of the spring in it. The axis of the spring and of the shaft coincide; the result of this is that it is hardly at all affected by centrifugal force. When springs of slight pull are used and the ergometer is driven at a great velocity, the deformation is considerable, and would introduce considerable error in the result.

The deformation of the spring has been fully appreciated and therefore Rev. Smith has placed the spiral springs of his ergometer in cylindrical cases. When the spring is placed with its axis coincidental with that of the machine, no such error can be introduced and the friction of a spring against a case is avoided.

Smith's Transmission Ergometer

Mammalian development

Methods and success of nuclear transplantation in mammals

from Anne McLaren

NATURE's own nuclear transplantation device, the fertilizing spermatozoon, provides cogent evidence for the role of the nucleus in heredity. The demonstration that cytoplasm too has a part to play had to await the exploitation by Danielli and his colleagues of a microsurgical technique of nuclear transplantation in *Amoeba*[1]. Soon after, Briggs and King succeeded in transplanting nuclei from cells of frog larvae into enucleated frog eggs[2]. Their initial results suggested that nuclei become restricted in potency as development proceeds; but in a long series of experiments Gurdon and his colleagues showed that cell differentiation does not necessarily result in irreversible nuclear changes[3]. Thus nuclei from differentiated intestinal cells of tadpoles injected into enucleated frog eggs can be reprogrammed by the egg cytoplasm so as to support the development of adult frogs[4]; however, while nuclei from cells of adult frogs can support the development of tadpoles, the tadpoles fail to metamorphose into adults[5,6]. The widespread belief that clones of adult frogs have been produced by transplanting nuclei from adult tissue is thus fallacious.

Still more fallacious, of course, is the account of human cloning in Rorvik's *In His Image*[7]. Indeed, nuclear transplantation in mammals has proved very difficult to achieve. Since a mammalian egg is a thousandth or less of the volume of a frog egg, this is hardly surprising. Microsurgical techniques have been devised both to remove single pronuclei from mouse eggs[8-10], giving haploid embryos, and to transplant embryonic nuclei into fertilized mouse eggs, giving a tetraploid chromosome complement[11]. Both procedures are followed by cleavage to the blastocyst stage, but attempts to combine the two procedures by transplanting nuclei into mouse eggs from which both pronuclei have previously been removed invariably lead to disintegration of the eggs (J.A. Modlinski, personal communication). Attempts have also been made to introduce nuclei from eight-cell embryos into unfertilized rabbit eggs[12], either by microsurgery or by virus-mediated cell fusion, but the success rate is low, and no more than two to three cleavage divisions are ever observed. Virus-mediated fusion of somatic cells with mouse eggs has shown equally little promise[13,14].

The first report of mice born from nuclear transplantation came from Illmensee and Hoppe[15]. The trauma of two operations on the same egg was avoided by injecting donor nuclei into fertilized eggs and then immediately sucking out the two pronuclei of the recipient, using the same pipette. The donor nuclei were taken from blastocysts: if from inner cell mass cells, the recipient eggs sometimes developed to term but if from trophectoderm cells development did not proceed beyond mid-cleavage. A similar difference was reported for nuclei transplanted to non-enucleated fertilized eggs to produce tetraploid embryos[16]: eggs receiving inner cell mass nuclei developed into blastocysts, but those receiving trophectoderm nuclei blocked at the eight-cell stage.

The microsurgical technique of Illmensee and Hoppe has not yet been successfully carried out in any other laboratory, though it has been attempted by at least four groups, and probably more. In contrast, a technique devised by McGrath and Solter[17] has already been used with success in our own laboratory[18] and another[19]. Their technique avoids the necessity of penetrating the plasma membrane of either the donor or the recipient egg by sucking out the pronuclei surrounded by a piece of plasma mem-

brane — a karyoplast. The donor karyoplast, together with some Sendai virus to promote fusion, is injected under the zona pellucida of the enucleated recipient egg, with which it fuses. The yield of live mice is very high when fertilized eggs are used as donors, but no successful development beyond the blastocyst stage has so far been reported with donor nuclei from older embryos.

One application of the technique has been to exchange pronuclei between fertilized eggs of different strains, so as to investigate whether the basis for maternal effects transmitted via the egg resides in the nucleus or in the cytoplasm at the time of fertilization. In this way expression of the stage-specific embryonic antigen SSEA-3 has been shown to depend on the egg cytoplasm[20], while the lethal effect of the hairpin tail mutation when transmitted through the mother seems to be a property of the pronuclei[21].

Another application has been to exchange pronuclei between fertilized and parthenogenetically activated mouse eggs in an attempt to understand the mysterious failure of parthenogenotes, whether haploid or diploid, to develop to term. When pronuclei from eggs parthenogenetically activated by alcohol treatment were transplanted by the McGrath and Solter technique into enucleated fertilized eggs, the embryos did not survive to term; but pronuclei from fertilized eggs, transplanted into parthenogenetically activated and then enucleated eggs, produced live mice[18]. This result suggests that the defect lies in the pronuclei, not in the cytoplasm. In contrast, when inner cell mass nuclei from parthenogenetic blastocysts were microsurgically transplanted into enucleated fertilized eggs, using as donors spontaneously activated LT/Sv embryos, Hoppe and Illmensee reported that they developed normally[22].

Diploid parthenogenetic embryos are a special case of embryos with two maternal and no paternal genomes: such embryos can also be derived by removal of the paternal pronucleus, followed by doubling of the remaining maternal pronucleus. Such homozygous diploids, whether formed from the maternal or paternal pronucleus, have been reported to develop to term[9], but attempts to confirm these results have not been successful[8,23,24].

Using the McGrath and Solter technique to exchange single pronuclei, it has recently been shown that normal development does not follow the addition of a second maternal pronucleus to a haploid parthenogenote, whereas the addition of a paternal pronucleus results in a viable embryo[19]. Also, while a paternal and a maternal pronucleus taken from fertilized eggs and recombined will support development, two paternal or two maternal pronuclei fail to do so[25]. Unless some extrachromosomal component of the pronucleus plays a hitherto unsuspected role in development, these two pieces of work suggest that normal development requires both a paternal and a maternal chromosome set.

Only when we understand the reasons for the developmental failure of certain categories of embryo will it be possible to assess the significance of these results as a whole. In attempting to resolve the apparently conflicting lines of evidence summarized above, certain points must be borne in mind. When pronuclei are sucked out with a fine pipette, some or all of the pronuclear membrane may remain behind even though the pronuclear contents are removed. When nuclei are transplanted, either by microinjection or cell fusion, some cytoplasm is also transferred. Eggs artificially activated by exposure to alcohol cannot necessarily be equated with spontaneously activated LT/Sv eggs. Finally, inner cell mass nuclei cannot be equated with pronuclei: it may be that by the blastocyst stage, developmental potential has become restricted; alternatively, some developmental block affecting the nuclei of parthenogenetic eggs may have been overcome by this stage.

A precedent is seen in the *o* maternal effect lethal of the axolotl. This involves a cytoplasmic effect such that eggs from homozygous females, that would otherwise die during gastrulation, can be rescued by injection of normal oocyte cytoplasm or nuclear sap at the one-cell stage[26]. Transplantation of normal nuclei into enucleated *o/o* eggs is followed by normal development if the donor nuclei are taken from mid-blastula or later embryos, but not if they are taken from early blastulae, suggesting that some heritable change takes place in the axolotl nucleus during the blastula stage[27].

What of the future? Now that mouse strains carrying mitochondrial variants[28] are available, the use of recipient eggs carrying a mitochondrial marker will provide unequivocal evidence that a mouse is indeed derived from a nuclear transplant, just as the one-nucleolus marker provided similar certainty for amphibian nuclear transplantation[3]. The McGrath and Solter technique can be used to analyse any maternal effect exerted via the egg[29], and also perhaps to examine the roles of nucleus and cytoplasm in oocyte maturation. But only if it can be extended to use nuclei from later stages of development, or if the Illmensee and Hoppe nuclear transplantation technique can be successfully repeated, will the type of analysis pioneered in Amphibia also become possible in mammals. Does the developmental potency of nuclei become irreversibly restricted in the course of differentiation? Can somatic nuclei be reprogrammed, perhaps by transfer through several successive oocyte hosts? Can even adult nuclei be persuaded to revert to their ancestral totipotent condition? If not, why not? Perhaps irreversible gene rearrangements during somatic development, of the type undergone by immunoglobulin genes in the development of antibody-producing B cells, are more common than we realize. Mammalian systems may throw light on these crucial questions, at present unanswered even in Amphibia.

The potential rewards in animal breeding are great, with the cloning of prize-winning animals as the ultimate goal. Unless it becomes possible to use adult nuclei for renucleation of enucleated eggs, it will not be possible to clone champions, as such. But if large numbers of genetically identical embryos could ever routinely be produced by breeders, using inner cell mass nuclei to renucleate eggs, most could be stored in frozen form while waiting to learn if a champion developed from one that was taken to term. If so, the frozen embryos could be thawed and transferred to foster mothers as required.

For human embryos, nuclear transplantation has a bad name because of the science fiction overtones of cloning; but for couples at risk of transmitting a genetic defect to their progeny, it could provide a method of screening that did not involve, as present methods do, termination of the affected pregnancies. If several eggs were recovered from a woman and renucleated with inner cell mass nuclei from one of her own embryos, a few could be frozen, while the genetically identical remainder were screened for a genetic defect, by chromosome analysis, DNA analysis or other biochemical methods. In this way it would be possible to assure the woman that any embryo transferred to her uterus from the frozen stock would be free of the screened-for genetic defect. □

Direct land/sea correlations in the last interglacial complex

Jean-Louis Turon

Département de Géologie et Océanographie, Institut de Géologie du Bassin d'Aquitaine, Avenue des Facultés, 33405 Talence Cedex, France

Isotopic and pollen analyses of an eastern Atlantic core permit the first direct correlation of substages 5e and 5c of the marine climatostratigraphical system with the Eemian and St Germain I, respectively, of the classical Grande Pile pollen sequence (north-east France). The vegetational sequences during the warm intervals of the last interglacial complex (125,000–75,000 yr BP) indicate that climatic deterioration occurred late on the mid-European continent after the initiation of glaciation over continental masses in high latitudes.

IN the reconstruction of the global climatic patterns of the succession of glacial and interglacial periods of the Quaternary, the correlation of deep-sea records and of continental data is of the first importance. Because the $\delta^{18}O$ signal in continuously deposited deep-sea records is chiefly determined by global ice-volume[1,2], it is globally synchronous in the open oceans and thus provides a basic climatic stratigraphy for oceanic events.

Unfortunately, land-based records cannot be easily correlated with the oceanic records. First, there are several independent climatostratigraphical systems[3] based on palynological data, studies of loess–soil succession and of the geomorphological and sedimentological features of terraces and moraines. Second, because many of the data extend beyond the ^{14}C time scale, their chronology is only poorly controlled. Finally, the discontinuity of continental records impedes inter-regional correlations. The result is that there is no reliable linkage between continental units and the now-standard oceanic ^{18}O succession[3,4].

This is true even for the last interglacial period (125,000–75,000 BP), which most closely resembles the present in climate and which might serve as a guide to future climatic conditions. Thus, in palaeoceanographic studies, oxygen isotopic data[5–8], changes in marine faunal assemblages[9–12], and carbonate curves[13], show that the last interglacial interval[5,7,9,14,15] (125,000–75,000 yr BP), which was the last globally warm period before the present, was characterized by a succession of three main warm phases separated by two cold phases. This palaeoclimatic history has been also recorded in ice cores[16,17] and in the succession of coral terraces[18,19].

In the oxygen isotope stratigraphy, the last interglacial interval corresponds to Emiliani's stage 5 (ref. 5) in which the oldest subdivision (Shackleton's substage 5e; ref. 7) can be regarded as the warmest period of the whole interglacial complex and at least as warm as today. Fragmentary continental records have revealed that a climate as warm as the present one certainly occurred during the Eemian stage in northwestern Europe. On the basis of similarities between climatic conditions recorded in deep-sea cores and continental sequences, Shackleton[7] first suggested that the northwestern European Eemian interglacial was the continental equivalent of substage 5e. But now it seems that in moraine systems there were three stratigraphically separate Eemian interglacials[3,4], and that numerous truncated Eemian deposits (including the type Eemian of the Netherlands) cannot be correlated with stage 5e. In fact, the best and most complete climatic succession through the last interglacial complex has been obtained later from the long continental sequences of Grande Pile (northeastern France)[20] and Tenagi Philipon (northern Greece)[21]. These sequences reveal that there was a succession of three warm intervals during the interglacial, as observed in the deep-sea record. Nevertheless, the striking resemblance between the climatic evolutions observed in both land and sea sequences does not necessarily imply precise synchronism between the successive parallel climatic events. Indeed, discrepancies remain concerning the real correlation of French Eemian, Greek Pangaion and subsequent warm periods with the oceanic stratigraphical framework of the last interglacial complex[20,22–25].

In view of the difficulties which are encountered in continental sequences, marine palynology seems to offer the most valuable method for direct land/sea correlations. It has recently been shown that pollen and spores contained in deep-sea sediments neighbouring coasts may indeed reflect the adjacent continental vegetation[26–28]. Moreover, marine palynological sequences without major lacunae can be directly correlated *in situ* with deep-sea isotope stratigraphy. Thus core records from the north-eastern Pacific[29] and Bay of Biscay[30] permit direct marine/continental correlation between events of the last deglaciation (20,000 yr BP–present). In the same manner, off the Washington–Oregon coast[31] and in the Arabian Sea[32], the correlation of the vegetational evolution of the last interglacial complex with the isotopic subdivisions of stage 5 has also been demonstrated.

By means of palynological studies from a deep-sea core located off Iberian coasts in the Atlantic ocean, I aim here:

(1) To determine, for the first time, the vegetational and palaeoclimatic evolution of the adjacent southwestern European continent during the last interglacial complex.

(2) To correlate continental events recorded in the present study, during isotopic substages 5e, 5d and 5c, with the lower part of the continuous palynological diagram from the Grande Pile peat-bog, which is today the nearest continental site to the deep-sea record studied.

(3) Thence, to correlate directly the lower part of Grande Pile sequence with the standard isotope $\delta^{18}O$ stratigraphy, which has been established in the marine core.

(4) To determine precisely the relation between the onset of ice growth phases in polar areas and the continental response in southwestern Europe to climatic changes, which occurred at the transition between warm isotopic substages 5e, 5c and the full glacial conditions of substages 5d and 5b.

Isotope and pollen records in core SU 8132

Core SU 8132 was recovered near the continental slope 100 km off the Iberian coast, near the Spanish–Portuguese border (42°06′N, 09°41′W, 2,280 m). As has already been shown in the Bay of Biscay[26], deep-sea sediments at the same distance from vegetated landscapes, contain numerous pollen and spores, the distribution of which reflects the regional vegetation of the adjacent continent.

Oxygen isotope records were made on the basis of analyses of the planktonic foraminifer *Globigerina bulloides* (>250 μm fraction)[2]. Because benthic $\delta^{18}O$ records are less influenced by

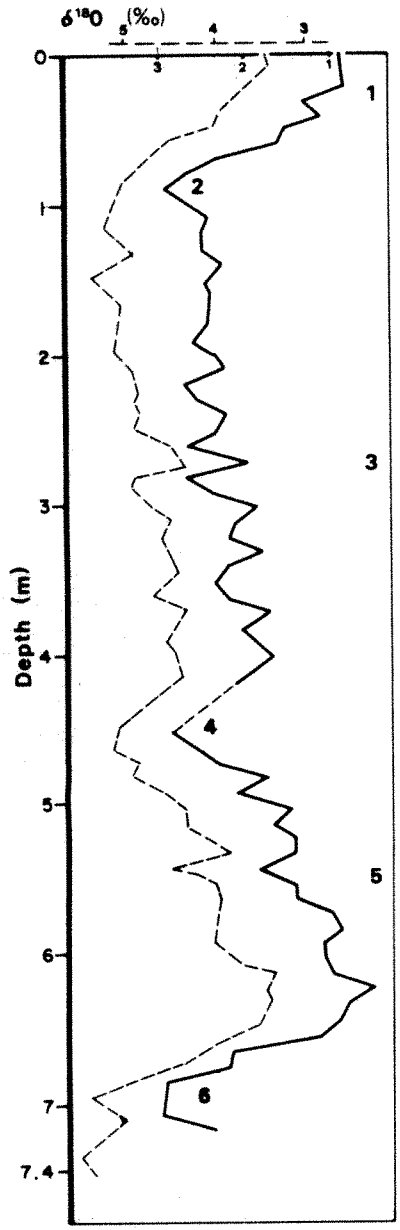

Fig. 1 Oxygen isotope, $\delta^{18}O$, record of planktonic foraminifer *Globigerina bulloides* (solid curve) and benthic foraminifers after normalization to *Uvigerina peregrina* (dotted curve) in core SU 8132, after J. C. Duplessy (personal communication).

local effects than planktonic ones[33], benthic foraminifera were also analysed to obtain a better isotope stratigraphical framework, primarily reflecting global ice volume evolution at high latitudes[34,35].

The $\delta^{18}O$ record (Fig. 1) shows that core SU 8132 represents a high sedimentation rate and gives a long continuous sequence with the classical development of Emiliani's stages[5] from 6 to 1. Unfortunately, during stage 5, Shackleton's upper substages[7] 5b and 5a are difficult to determine because of the low rate of sedimentation at that time, and/or the disturbed nature of the sediment. By contrast (Fig. 2), substage 5e is well developed from 680 to 580 cm, representing a high sedimentation rate for this period (100 mm kyr^{-1}). The glacial/interglacial change at the 6/5e boundary is marked by a major shift at 680 cm corresponding to Termination II of Broecker and Van Donk[14]. Substage 5c is also identifiable between the two major $\delta^{18}O$ increases at 540 cm (substage 5d) and 490 cm (lower boundary of 5b). There is another major $\delta^{18}O$ shift corresponding to the stage 4/stage 3 boundary at 420 cm.

In core SU 8132, palynological analysis has only been applied to the interval between stages 6 and 3. Samples were treated according to classical methods: HCl, HF and heavy liquor, and sieving on 15–20 μm mesh. Some 100–200 grains were counted (excluding *Pinus* (pine) pollen). To delete the overrepresentation of *Pinus* pollen grains that affects pollen profiles in marine sediments[36], percentage evaluations on Fig. 2 were based on the total pollen grains, including AP (arboreal pollen minus *Pinus* pollen), and NAP (non-arboreal pollen) and spores of ferns. The pollen diagram shows warm intervals in which temperate tree pollen dominates, alternating with cool intervals in which non-arboreal pollen is relatively more important.

At the end of stage 6, pollen spectra reflect an open cool vegetation (Graminae, Cyperaceae, Ericaceae, rare *Artemisia* and other Compositae) representing up to 95% of the basic sum. Arboreal pollen (except for *Pinus*) is very rare. At the boundary of stage 6/substage 5e, Termination II is very well marked by the immigration of *Betula* (birch) and the first appearance of *Quercus* (oak) (pollen zone 2). The early part of substage 5e is characterized by the maximum relative value of *Quercus* (pollen zone 3). Abundant *Quercus* is accompanied by a noticeable increase in *Carpinus* (hornbeam) (pollen zone 4), followed in the latter part of substage 5e by the well-marked development of *Abies* (fir) and a slight spread of *Betula* (pollen zone 5). At the 540-cm level, the pollen profile reflects the return of cold conditions with a major drop in the AP curve directly correlated with the cold event 5d (pollen zone 6). The sharp $\delta^{18}O$ decrease which followed (substage 5c) is characterized by the dominance of temperate tree pollen, with an early *Quercus–Carpinus* succession accompanied by a slight increase in *Abies* (pollen zones 7, 8 and 9).

Another short-lived disappearance of temperate forest occurs in pollen zone 10. Pollen zone 11 is characterized by a slight immigration of *Quercus*, but the landscape is dominated throughout by herbaceous plants. As has been previously noted, the sedimentary sequence of this part of core SU 8132 seems disturbed and, therefore, the vegetational record could be either discontinuous or mixed.

Pollen zones 12 and 13 at the top of the sequence show an alternation between assemblages without forest development, which corresponds to stage 4, and an increasing proportion of temperate trees (*Betula, Quercus, Abies*) correlated closely with the early part of stage 3.

Thus marine pollen analyses from core SU 8132, being directly correlated with oxygen isotope stratigraphy, show for the first time that during the early and middle part of stage 5, the palaeoclimatic evolution of the neighbouring western Iberia was characterized by a succession of two warm phases (5e = pollen zones 2–5; 5c = pollen zones 7–9) separated by an abrupt and very cold interval (5d = pollen zone 6).

Moreover, during the two older warm periods of stage 5 (5e and 5c) a logical succession is observed in the immigration of various temperate trees starting after the glacial episodes (6 and 5d)—early development of *Betula* soon replaced by the immigration of *Quercus*, then marked extension of *Carpinus* and a late increase in *Abies*. This vegetational evolution is in good agreement with the main criteria taken in continental pollen sequences to charcterize, from a palynological point of view, a complete interglacial cycle[25,37–40]. By comparison, the early part of stage 3, which is marked by the simultaneous immigration of *Betula, Quercus, Abies* and lack of *Carpinus*, must be interpreted as an interstadial period.

It can be seen that the pollen assemblages from substage 5e and the pollen assemblages from substage 5c are generally similar but 5e slightly differs from 5c in the more important role of *Abies* in the latter part of the episode.

Correlation with continental sequence

Many continental sequences covering the last interglacial climatic cycle in northwestern Europe have been studied by means of pollen analyses[41–46]. They indicate that a warming period, for example, the classical Eemian[47,48] in Holland, occurred

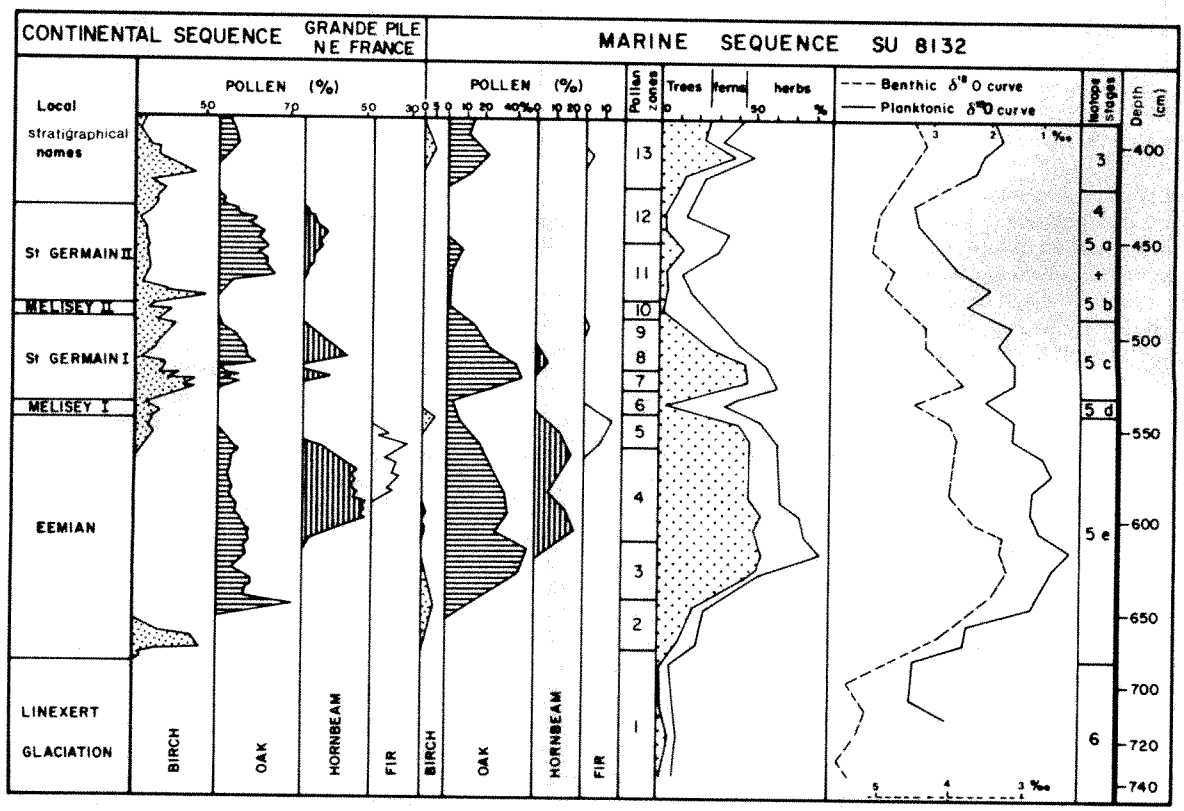

Fig. 2 Direct correlation of $\delta^{18}O$ stages with the continental sequence of Grande Pile by means of the marine palynological sequence of core SU 8132. Continental sequence after ref. 20. Benthic and planktonic $\delta^{18}O$ after J. C. Duplessy (personal communication). In the marine sequence, the relative frequency for pollen of tree species is expressed as a percentage of the total pollen+spores, excluding pine pollen.

below the last Weichselian glaciation. Unfortunately, few continental deposits apparently contain a continuous pollen record extending over the entire last interglacial complex. Lack of evidence for a complete record of subsequent climatic evolution up to the present interglacial, and absence of accurate absolute dating methods have often posed the problem of their real place in the interglacial/glacial succession of continental climato-stratigraphical systems[3,4,49]. One of the best and most complete sequences known at present is from the Grande Pile in north-east France[20]. Figure 2 shows that between the end of a long glacial period (? Saale, ? Warthe) and the beginning of the Würm glaciation, which is radiometrically dated at ~70,000 yr BP (ref. 50) there were three temperate intervals, namely Eemian, St Germain I and St Germain II, separated by two very cold phases, Melisey I and Melisey II (Fig. 2). Furthermore, the early warm period (Eemian) is characterized by the successive extension of the tree species *Betula*, *Quercus*, *Carpinus*, and *Abies*, very similar to that recognized in core SU 8132 during isotopic substage 5e. In the Grande Pile record St Germain I slightly differs from the Eemian mainly in the lack of *Abies*, in the same manner that the development of *Abies* in marine substage 5c is less important than in 5e. As in the marine record during 5d, palynological evidence from Grande Pile shows that Melisey I was an abrupt and very cold period which separated the two older warm intervals of the interglacial complex. However, some Eemian and St Germain I interglacial features do not occur in the deep-sea record: there is a lack of *Picea* (spruce) and *Corylus* (hazel) phases, and a lower species diversity of herbaceous taxa. These can be explained by taking into account the southerly position of core SU 8132, the selective effect of the regional (but not local) origin and marine transport processes of the marine pollen assemblage[26]. Therefore, despite some slight differences, the marine pollen diagram exhibits the same climatic trends, and a similar general succession of vegetation landscapes as in north-east France and there now seems to be no doubt that Woillard's Eemian and St Germain I interglacial periods correspond, in core SU 8132, to substages 5e and 5c respectively, and that Melisey I correlates closely with substage 5d.

Despite some controversies in earlier estimates[15,51–53], there is now general agreement on assigning dates of ~125,000 and 75,000 yr BP to Emiliani's stage 6/5 and 5/4 boundaries respectively[54–56]. Radiometric dating of coral terraces[14], and $\delta^{18}O$ time scales determined by assuming a constant sedimentation rate, are so similar that a correlation of the three $\delta^{18}O$ minima 5e, 5c, 5a and high sea level stands on Barbados at about 125,000, 104,000 and 80,000 yr can be demonstrated[15]. Therefore, extrapolated ages for the two cold peaks (5d, 5b) can be estimated as 110,000 and 90,000 yr BP, respectively.

These peaks are synchronous within the mixing time of the world's ocean waters, and the marine palynological evidence of SU 8132 allows us to conclude that Woillard's Eemian and St Germain I interglacials are correlated with Barbados I and Barbados II, while the lower boundaries of Melisey I and II can be placed at ~115,000 and 95,000 yr BP respectively.

This direct correlation between deep-sea chronology and the lower part of the continental stratigraphical sequence from Grande Pile confirms and gives precision to the previously hypothetical correlations suggested by Woillard and Mook[50] for this interglacial complex. Conversely, the results of the present study invalidate correlations of the Eemian interglacial with the whole of stage 5 or with substages 5e, 5b, 5c combined, as suggested by Morner[23,24].

Continental vegetation and ice sheet growth

In core SU 8132, the oxygen isotopic curve based on benthic foraminifera shows that after a well marked minimum in the lower part of substages 5e and 5c, $\delta^{18}O$ values began to increase within the middle part of these two warm interglacials long before the onset of glacial substages 5d and 5b (Fig. 2). This would indicate that an early phase of ice growth took place in polar latitudes before the end of both Eemian and St Germain I time. From numerous North Atlantic cores, Ruddiman *et al.*[57]

observed a similar trend across both 5e/5d and 5a/4 transitions.

Moreover, pollen data from core SU 8132 (Fig. 2) clearly indicate that the beginning of each ice growth (at 610 and 520 cm) is directly correlated with pollen zones 4 and 8 respectively, which are both characterized by the spreading of *Carpinus*. From pollen assemblages recorded in continental deposits during past interglacials it appears that the classic *Carpinus* phase is often marked by the presence of thermophilous plants such as *Ilex*, *Buxus*, *Hedera* and *Viscum*[20,40,41,47,58]. Thus, it may be assumed that the *Quercus–Carpinus* vegetational succession does not indicate climatic deterioration but, on the contrary, general stability of warm temperatures during the climatic optimum of each interglacial period. According to Andersen[58] this classical succession of vegetation landscapes could be conditioned by soil evolution rather than by climatic change. In fact, from the SU 8132 sequence it appears that temperatures in southwestern Europe probably began to decrease only with the immigration of *Abies*, which occurred at the end of both interglacial intervals, but that full glacial conditions, marked by high amounts of herbaceous plants, did not start before major ice volumes had been accumulated in Arctic zones during substages 5d and 5b. All these data indicate that the initiation of Boreal ice caps, during the second half of the Eemian and St Germain I interglacials, did not correlate with a temperature decrease in southwestern Europe, probably because an ice cover was not yet established over Scandinavia.

This pattern agrees well with the evolution of palaeotemperatures in the northeastern Atlantic ocean at interglacial to glacial transitions during stage 5. By means of matched isotopic and marine faunal data, Ruddiman and McIntyre[59] pointed out the existence between 40° N and 60° N of warm, eastern North Atlantic sea-surface temperatures during the first half of rapid ice growth. They speculated that along with low summer insolation, which occurred at the 5e/5d and 5a/4 transitions, an 'interglacial' warm Atlantic Ocean might be a necessary condition for delivering moisture to high latitude areas, thereby leading to the initiation of extensive glaciation.

Moreover, according to Royer *et al.*[60], the cooling linked to the insolation change, which occurred around 115,000 yr BP, was not uniformly distributed over the northern high latitudes, but has a well defined maximum, combined with increased precipitation, over North America. These data suggest that initial high-latitude glaciation was established on the western side of the North Atlantic Ocean. In this context, evidence from the SU 8132 record indicates that the initiation of the Laurentide ice sheet did not cause a temperature decrease in southwestern Europe, and probably excluded the simultaneous inception of ice caps in Scandinavia. It is only later, at the end of the interglacial periods, that the disappearance of *Carpinus* forest and extension of *Abies* phases probably indicates the mid-European continental response to the onset of glaciation over Scandinavia.

Finally, the present study provides additional data on a parallel climatic evolution between the eastern North Atlantic Ocean and the adjacent European continent, and on the diachronous inception of ice caps on either side of the North Atlantic Ocean. This pattern agrees well with a drop in sea level during the Eemian while the contemporaneous climate in western Norway probably inhibited the growth of any large ice-masses in Scandinavia[46]. A marked cooling of sea-surface temperatures, which occurred in the western North Atlantic and in the North Pacific[61], while both the eastern North Atlantic and the adjacent European continent remained warm, could probably be regarded as a natural trend which might have later promoted the transition to full glacial conditions in the Northern Hemisphere.

I acknowledge the support of the CNRS Programme National d'Etude de la Dynamique du Climat. I thank Dr J. C. Duplessy for isotopic analyses and comments on an early version of the manuscript, Dr L. E. Heusser and Dr A. McIntyre for critically reading and making valuable suggestions on this work. This work was supported by the European Community Committee under grant no. CL-005-F.

Reverse gyrase—a topoisomerase which introduces positive superhelical turns into DNA

Akihiko Kikuchi & Keiko Asai

Mitsubishi-Kasei Institute of Life Sciences, 11 Minamiooya, Machida-shi 194, Tokyo, Japan

An enzymatic activity which converts closed circular DNA into a positively supercoiled form is present in cellular extracts of Sulfolobus, *an acidothermophilic archaebacterium. This novel enzyme is a type II DNA topoisomerase and is active only at temperatures > 55 °C, in the presence of ATP and* Mg^{2+}.

THE topological state of DNA[1] affects its replication[2,3], recombination[4–6], gene expression mediated by transcription[7,8] and nucleosome assembly[9–11]. DNA topoisomerases have been detected in a variety of organisms[1] and have been characterized and classified into two categories: type I topoisomerases transiently cut one of the two DNA strands to change the linking number in steps of one and type II topoisomerases act by means of a transient double-stranded break, which results in changing the linking number by two steps at a time. In eukaryotic cells, the type I enzyme, the so-called 'nicking–closing' enzyme, is predominant. This enzyme acts on both negatively and positively supercoiled DNAs, removing their superhelical turns. An ATP-requiring type II topoisomerase was first discovered by its particular ability to catenate and decatenate[12,13] or to unknot the entangled DNA rings[14,15]. This type II enzyme can also remove both negative and positive superhelical turns from DNA. In a typical bacterial extract, two types of topoisomerases are detected: ω-protein (type I) which relaxes negatively but not positively supercoiled DNA, and DNA gyrase (type II) which introduces negative superhelical turns into DNA[16].

Archaebacteria are believed to be a third type of organism[17] which have various characteristics distinct from those of eukaryotes or prokaryotes. We surveyed topoisomerase activities in extracts of *Sulfolobus*, an acidothermophilic archaebacterium, and found two remarkable features. First, in contrast to other organisms, ATP-requiring type II topoisomerase activities prevailed and were easily fractionated into three different enzymatic preparations, while type I topoisomerase activity was negligibly small. Second, one of the type II topoisomerases was able to introduce positive superhelical turns into DNA. We have tentatively named this new enzyme reverse gyrase and discuss possible implications of its biological function.

Identification of topoisomerases

Topoisomerase activities were surveyed in the following four conditions: (1) Relaxation of negatively supercoiled DNA was measured in the presence of EDTA, to detect eukaryotic type I nicking–closing activity. (2) The same conditions as for condition (1) but Mg^{2+} was added instead of EDTA, to detect ω-like activity (type I). (3) The same conditions as in condition (2) except that 1 mM ATP was included (type II). (4) Supercoiling of relaxed DNA was assayed in the presence of ATP and Mg^{2+}, to detect a gyrase-like activity (type II).

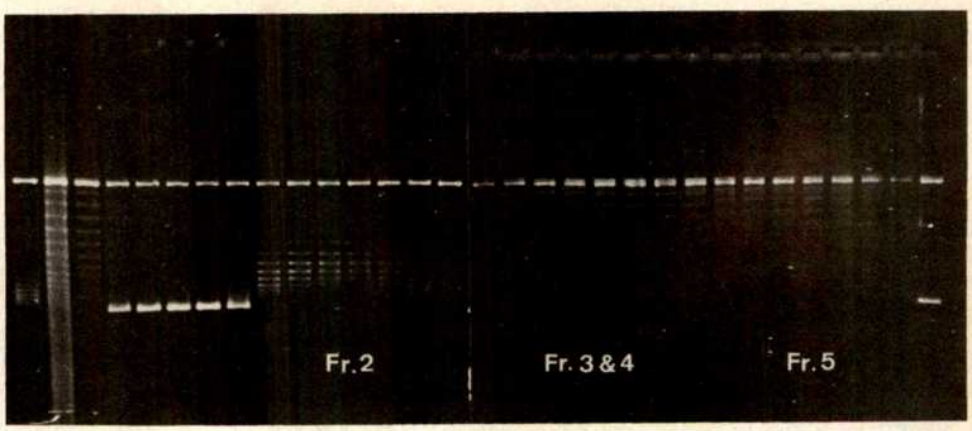

Fig. 1 Fractionation of topoisomerase activities. Lane 1, the activity in the crude extract; all the other lanes show the activity in each fraction of the column.

Methods: The *Sulfolobus acidocaldarius* strain 7 (FERM P-7137, Fermentation Research Institute, Japan) used in this study was similar but not identical to *S. acidocaldarius* strain DSM 639 (ref. 32). The antiserum raised against pure RNA polymerase of the strain DSM 639 (provided by Dr W. Zillig) cross-reacted with that of our strain 7, although the molecular weights of each subunit examined by SDS-polyacrylamide gel electrophoresis were not identical between the two strains (unpublished results). Cells were grown at 75 °C for 24 h with aeration in medium containing 0.1% yeast extract, 0.1% polypeptone, 0.1% casamino acids, 0.1% glucose, 0.2 g l^{-1} NaCl, 1.3 g l^{-1} $(NH_4)_2SO_4$, 0.3 g l^{-1} KH_2PO_4, 0.25 g l^{-1} $MgSO_4$, 0.07 g l^{-1} $CaCl_2$ and 2.5–5 ml 1M H_2SO_4 to adjust the *p*H to 3.0. About 1.7 g (wet weight) of cells obtained from 2 l of culture were suspended in 50 mM Tris-HCl *p*H 7.5, 10% sucrose, 1 mM EDTA–Na_3 and 10 mM β-mercaptoethanol and disrupted by three cycles of freeze-thawing. Two successive centrifugations were done, first at 12,000 r.p.m. for 30 min to remove cell debris, then at 40,000 r.p.m. for 2 h to obtain a clear supernatant (crude extract). The crude extract was adsorbed to a DEAE–Sephacel column (1.2 × 6 cm) in the same buffer as above except that 10% glycerol was used instead of 10% sucrose, then fractionated with a linear gradient from 0.025 M to 0.5 M NaCl. Topoisomerase activity in each fraction was measured in a standard assay mixture (35 mM Tris-HCl *p*H 7.5, 1.8 mM spermidine-$(HCl)_3$, 0.14 mM EDTA–Na_3, 5 mM dithiothreitol, 24 mM KCl, 10 mM $MgCl_2$, 1 mM ATP, 90 μg ml^{-1} tRNA and 8.7 μg ml^{-1} of negatively supercoiled pBR322 DNA as a substrate) at 65 °C for 1 h. The reaction was stopped by adding 1% SDS, 10 mM EDTA–Na_3 and 5% glycerol, and the relaxation in superhelicity of pBR322 DNA was monitored by 1% agarose gel electrophoresis at room temperature in 89 mM Tris-base, 90 mM boric acid, 2.5 mM EDTA–Na_3. A ladder of DNA bands, each representing one topoisomer, was visualized after gels were stained in 0.5 μg ml^{-1} EtBr. The three peak fractions of relaxing activities shown here were pooled separately and adsorbed to a phosphocellulose column (0.6 × 5.5 cm) equilibrated with 20 mM K-phosphate *p*H 7.0, 10 mM β-mercaptoethanol, 0.1 mM EDTA–Na_3 and 10% glycerol. A linear gradient of NaCl (0–1.0 M) was applied to recover the topoisomerase activities. The active fractions Fr.2, Fr.3, Fr.4 and Fr.5 (described in Table 1) were dialysed against 50 mM Tris-HCl *p*H 7.5, 0.1 mM EDTA–Na_3, 10 mM β-mercaptoethanol and 50% glycerol. All steps were carried out at room temperature. Each fraction was stored at −20 °C and remained active for 2 yr.

Table 1 Properties of the topoisomerases found in *Sulfolobus*

	DEAE–Sephacel (NaCl, M)	Phospho-cellulose (NaCl, M)	MW × 10^3	Require-ment	Relaxation of negative super-coil	Relaxation of positive super-coil	Unknot-ting	Catena-tion	Super-coiling	Linking number change
Fr.2	0.1–0.15	0.4–0.5	200	Mg, ATP	+ + +	+ + +	+	+ + +	+ +	2
Fr.3	0.15–0.3	0	330	Mg	+ +	−	−	−	−	1
Fr.4	0.15–0.3	0.6–0.7	500	Mg, ATP	+ + +	−	+	+	+ + +	2
Fr.5	0.3–0.5	0	460	Mg, ATP	+ + +	+ + +	+ + +	−	−	2

The molecular weight (MW) of each topoisomerase activity was estimated by sedimentation in a 20–40% glycerol gradient at 45,000 r.p.m. for 20 h with the following internal markers: β-galactosidase, bovine serum albumin, haemoglobin and cytochrome *c*. The relaxation of positively supercoiled DNA was tested by adding excess EtBr to the standard assay mixture (see Fig. 1 legend). EtBr was extracted with *n*-butanol before agarose gel electrophoresis. The product of Fr.4 enzyme was also used as a positively supercoiled substrate. Unknotting activity[14] was detected in the standard assay condition at 65 °C using knotted DNA extracted from P4 defective (tail-less) particles. A DNA band appeared at the position corresponding to the size of the P4 relaxed circle in the presence of ATP, whereas without enzyme or ATP no discrete bands were obtained. When incubation was at 75 °C, knotted DNA was pretreated with T4 DNA ligase to seal nicks at the cohesive ends[15], otherwise a non-enzymatic reaction occurred. Catenating activity[12,13] was judged from the DNA remaining at the top of the gel (see Fig. 3*c*, lane 4, for example), which was visualized as large aggregates under the electron microscope. Decatenating activity was measured by using these aggregates as a substrate.

As *Sulfolobus* grows at ~75 °C and not at temperatures <60 °C, incubation was at 65–75 °C for 1 h, after which the reaction was stopped by adding EDTA and SDS at room temperature, and the change in the linking number of closed circular DNA was monitored by agarose gel electrophoresis. No enzymatic activity in the crude extract was evident in conditions (1), (2) or (4), whereas a small amount of activity was detected in condition (3).

The crude extract was fractionated by DEAE–Sephacel chromatography. Figure 1 shows that activities in condition (3) above which relaxed negatively supercoiled DNA were detected in three separated fractions (Fr.). Each peak fraction was pooled and applied to a phosphocellulose column for further purification. The first peak and the third peak of the DEAE–Sephacel column exhibited single activities (Fr.2 and Fr.5), both requiring ATP. The second peak was divided into two fractions, one (Fr.3) active in the absence of ATP and the other (Fr.4) requiring ATP. The relaxation activity of each fraction sedimented at a unique position on glycerol gradient centrifugation, from which the molecular weight of each enzyme was estimated. Other activities such as supercoiling, unknotting of knotted P4 DNA[14,15] and catenation[12,13,15], were assayed for each enzyme preparation. The activity in Fr.4 is the main subject of this paper. The characteristics of the other topoisomerases are briefly summarized in Table 1 and will be reported in detail elsewhere.

Staggered ladders of DNA topoisomers

The enzymatic activity in partially purified Fr.4 was absolutely dependent on the addition of Mg^{2+} and ATP (Fig. 2*a*), and was demonstrably a type II topoisomerase[16]. The Fr.4 enzyme relaxed a DNA of unique negative superhelicity by two linking number changes at a time (Fig. 2*b*, lane 3). When relaxed DNA was used as a substrate, Fr.4 was able to introduce superhelical turns into DNA (Fig. 2*c*), showing ladders (a set of DNA topoisomers with different superhelicities) migrating more rapidly on agarose gel electrophoresis[17]. However, this gyrase-like activity was not evident at all with a DNA substrate of a defined negative superhelical density. Figure 2*b*, lane 3, shows that the Fr.4 enzyme could not negatively supercoil this substrate further but only relax it. By contrast, a more negatively supercoiled band was formed by the Fr.2 enzyme (Fig. 2*b*, lane 4), which served as a control for the gyrase activity. Furthermore, the position of each band of the ladders formed by the Fr.4 enzyme was slightly different and staggered compared with the

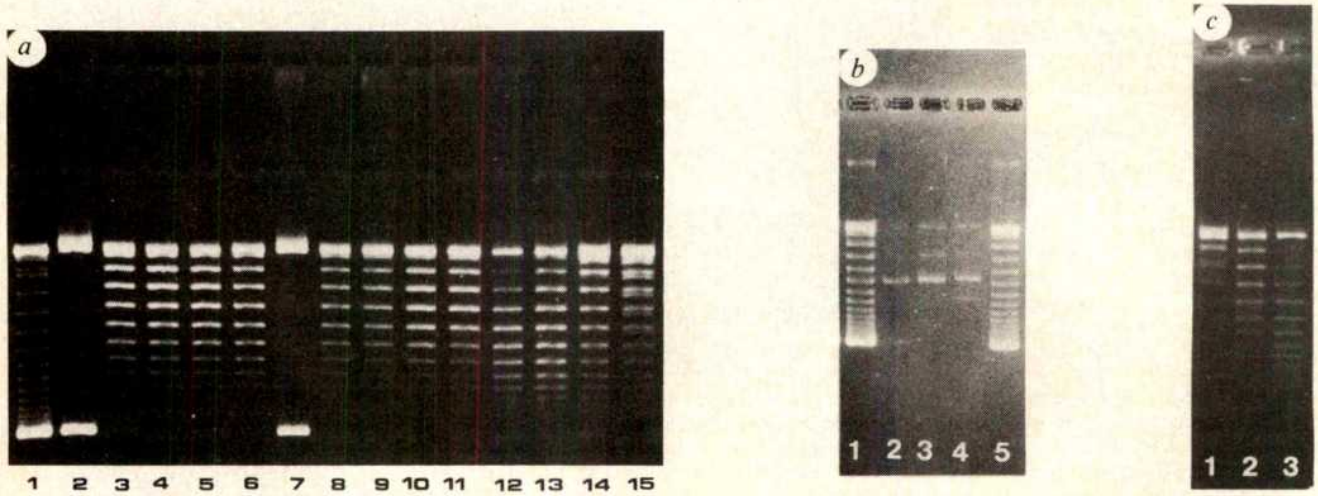

Fig. 2 Topoisomerase activity in Fr.4. *a*, Determination of the concentrations of Mg^{2+}, ATP and KCl optimal for Fr.4 activity. Each component was omitted from the standard assay mixture and then various amounts were added as indicated. Lane 1, pBR322 (negatively supercoiled topoisomers). Lanes 2–6, effect of Mg^{2+} concentration (0, 5, 10, 15 and 20 mM added in lanes 2–6, respectively). Lanes 7–11, effect of ATP concentration (0, 0.1, 0.2, 1 and 2 mM, respectively). Lanes 12–15, effect of KCl concentration (0, 50, 100 and 150 mM, respectively). *b*, Change of the linking number. A DNA band corresponding to a unique negative superhelicity was extracted from the ladder in agarose gel, and incubated with Fr.4 in conditions chosen to produce as minimal a change in linking number as possible. pBR322 DNA with a unique superhelical density (lane 2) was incubated with Fr.4 (lane 3) or Fr.2 (lane 4). The Fr.2 enzyme serves as a control demonstrating the linking number change by +2 and −2. Lanes 1 and 5 represent markers of negatively supercoiled topoisomers of pBR322. *c*, Supercoiling activity. Relaxed pBR322 DNA (lane 1) was used as a substrate in the standard condition and was incubated with Fr.4 at 65 °C (lane 2) or 75 °C (lane 3).

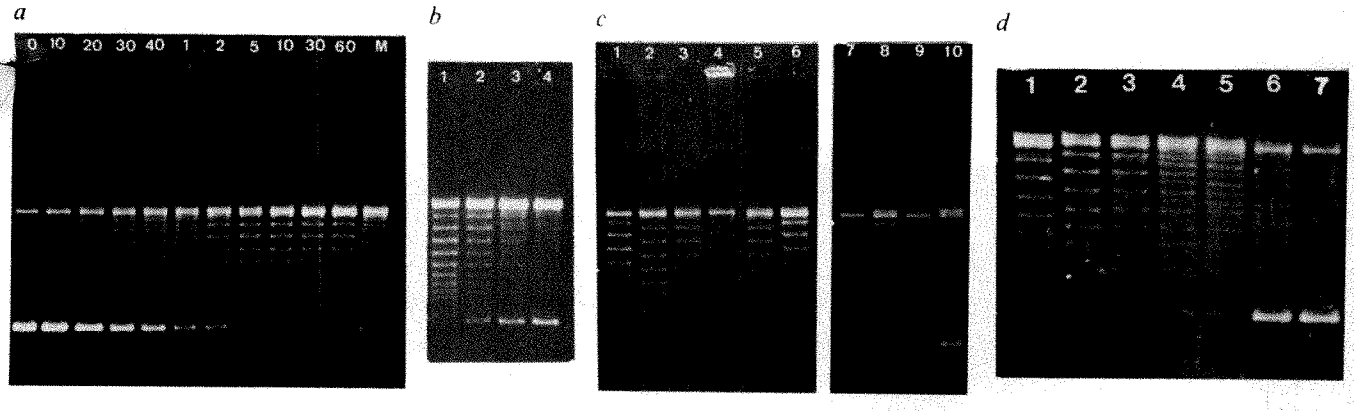

Fig. 3 Staggered ladders formed by Fr.4 enzyme. *a*, The time course of Fr.4 activity was monitored in standard assay conditions using 0.3 μg of Fr.4 protein and 0.26 μg of negatively supercoiled pBR322 DNA as a substrate. The reaction was stopped at the time indicated at the top of the column: 0, 10, 20, 30, 40 s, then 1, 2, 5, 10, 30, 60 min. The lane labelled M shows negatively supercoiled topoisomers of pBR322 prepared by yeast nicking–closing enzyme. *b*, Fr.4 activity was examined by changing the enzyme concentration. The amount of protein in each reaction mixture was (lanes 1–4, respectively): 0.15 μg, 0.03 μg, 0.015 μg and 0.003 μg. *c*, Interconversion of staggered ladders by other topoisomerases. Lane 1, a set of negatively supercoiled pBR322 topoisomers prepared with Fr.2 (standard ladder). Lane 2, Fr.4 was added to the sample prepared as in lane 1 and incubated further. The ladders were staggered. Lane 3, the reaction product of Fr.4 (staggered ladders). Lane 4, Fr.2 was added to lane 3 and incubated further. The ladder converted to the standard one and the catenated DNA also. Lane 5, same as lane 3. Lane 6, Fr.5 was added to lane 5 and incubated further. Lane 7, same as lane 3. Lane 8, yeast nicking–closing enzyme was added to lane 7 for further incubation at 30 °C. Lane 9, *E. coli* ω-protein was added to lane 7 for further incubation at 37 °C. Lane 10, a set of negatively supercoiled pBR322 topoisomers prepared by yeast nicking–closing enzyme (standard ladder). *d*, Catalytic nature of the enzyme. pBR322 DNA (0.26 μg) was included in each reaction mixture, while the amount of protein in the purified enzyme fraction was (lanes 2 to 7, respectively) 0.012 μg, 0.006 μg, 0.003 μg, 0.0015 μg, 0.0006 μg and 0.0003 μg. Lane 1 serves as a marker of negatively supercoiled topoisomers of pBR322 prepared by yeast nicking–closing enzyme (at 30 °C for 10 min). Note that a nicked circle, a relaxed circle, and supercoils with one positive turn and with one negative turn overlap with the two topmost bands of the ladders. The marker (lane 1) is rich in negatively supercoiled (−1 turn) and relaxed circles, while many nicked circles are found in the sample incubated at 75 °C (lanes 2–7). This explains a slight difference in the position of the top band in lane 1.
Methods: *d*, Fr.4 was further purified on a hydroxylapatite column equilibrated with 0.1M phosphate buffer (*p*H 7.0) containing 0.25 M NaCl. The topoisomerase activity was eluted by a linear gradient of phosphate (0.1–1.0 M). An active fraction recovered at 0.35 M phosphate was used for this experiment. The protein concentration was measured using Bio-Rad protein assay reagents. As the moecular weight of the enzyme was estimated to be ~500,000 (close to the β-galactosidase marker in glycerol gradient centrifugation), the molar ratio of protein to pBR322 DNA was calculated to be (lanes 2–7, respectively): 0.24, 0.12, 0.06, 0.03, 0.012 and 0.006.

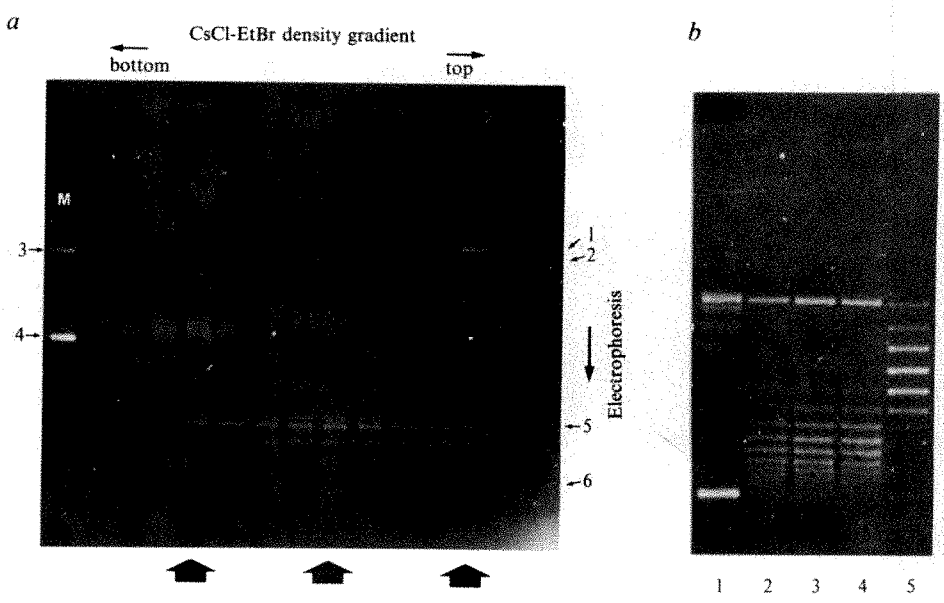

Fig. 4 CsCl–EtBr density gradient centrifugation. *a*, The first lane (indicated by M) is a size marker for pBR322 DNA. All the other lanes correspond to fractions from the CsCl–EtBr density gradient. Only an appropriate part of the gel is shown, where covalently closed circular DNA is present. The numbers indicate the positions of the following DNAs: (1) dimeric pBR322 (negatively supercoiled), (2) pBR322 (nicked circle), (3) pBR322 (relaxed circle), (4) pBR322 (negatively supercoiled), (5) pAO3 (relaxed or nicked circle), (6) pAO3 (negatively supercoiled). *b*, The pattern of the pBR322 DNA in the peak fraction compared with that of standard samples of negatively or positively supercoiled DNA. Lane 1, negatively supercoiled topoisomers of pBR322. Lanes 2–4, peak fractions of positively supercoiled pBR322 shown in *a*. Lane 5, positively supercoiled topoisomers of pBR322.
Methods: *a*, Negatively supercoiled pBR322 (4.3 kilobases, kb) treated with Fr.4 enzyme, was mixed with negatively supercoiled pAO3 (1.8 kb) DNA treated with Fr.5 enzyme (a marker for relaxed DNA at 75 °C) and a negatively supercoiled dimer of pBR322 (8.6 kb) (a marker for negatively supercoiled DNA at 37 °C). The solution was adjusted to 3.7 ml in 10 mM Tris-HCl *p*H 7.8, 10 mM EDTA–Na_3. After adding 3.8 g of solid CsCl and 0.3 ml of 5 mg ml^{-1} EtBr, the mixture was centrifuged in the RTV65 vertical rotor of the Hitachi ultracentrifuge (35,000 r.p.m. at 20 °C for 48 h). The gradient was fractionated from the bottom and DNA was extracted twice with *n*-butanol. After dialysis against 10 mM Tris-HCl *p*H 8, 1 mM EDTA–Na_3, each fraction was anlysed by 1.0% agarose gel electrophoresis. *b*, Positively supercoiled topoisomers were prepared by incubating negatively supercoiled pBR322 DNA with yeast nicking–closing enzyme at 4 °C for 24 h. The resultant molecules were positively supercoiled when assayed at 24 °C (ref. 19).

negatively supercoiled topoisomers prepared by yeast nicking–closing enzyme (Fig. 2*a*, compare lane 1 with the rest).

In favourable conditions of gel electrophoresis, the staggered bands formed by Fr.4 enzyme migrated just between the standard array of negatively supercoiled topoisomers, prepared either by yeast nicking–closing enzyme or Fr.2 or Fr.5 enzyme (compare Fig. 3*c*, for example). The time course of the reaction with Fr.4 enzyme (see Fig. 3*a*) demonstrated that in a short incubation time, two sets of the ladders, regular and staggered, appeared and as time progressed, the former bands disappeared and the latter ones intensified. A similar pattern was observed with decreasing amounts of enzyme, where doublet ladders were evident (see Fig. 3*b*). These results suggested that staggered ladders were formed via standard ladders when the reaction proceeded further. The pattern of the staggered ladder was not affected by further deproteinization with phenol and chloroform–isoamyl alcohol. It converted to a normal (negatively supercoiled) ladder after treatment with Fr.2 enzyme, which contained DNA gyrase and DNA catenase activity (Fig. 3*c*, lanes 3, 4), or with Fr.5 enzyme, a type II topoisomerase which could relax both negative and positive supercoils (Fig. 3*c*, lanes 5, 6). Therefore, this staggered ladder must be attributed to the DNA topoisomers. The reaction product of Fr.4 enzyme was next treated with either yeast nicking–closing enzyme or *Escherichia coli* ω-protein. The former catalysed the relaxation of staggered ladders but the latter could not (Fig. 3*c*, lanes 7–9). As distinct from the yeast enzyme, ω-protein does not relax positively supercoiled DNA. This result suggests that the staggered ladders comprise positively supercoiled DNA topoisomers.

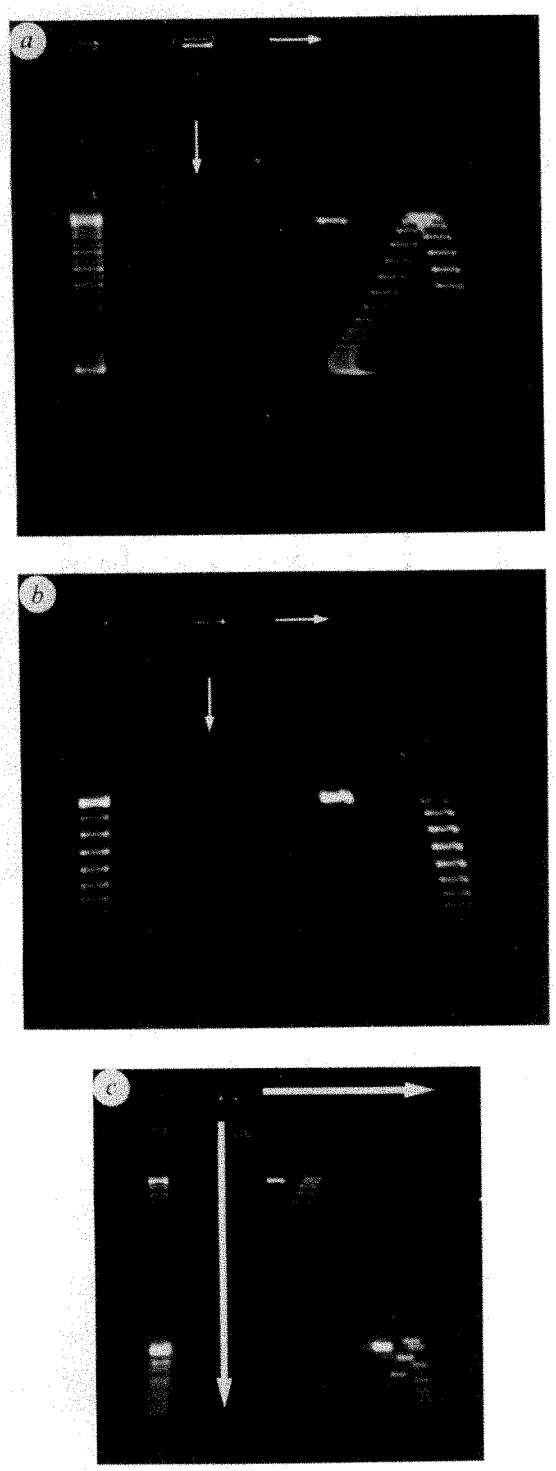

Fig. 5 Two-dimensional agarose gel electrophoresis. *a*, A mixture of negatively supercoiled pBR322 and positively supercoiled pBR322 prepared as described for Fig. 4*b* was electrophoresed in the first dimension in the standard conditions. The gel was soaked in 0.02 μg ml^{-1} EtBr solution for 90 min and re-electrophoresed in the orthogonal direction in the same buffer containing 0.02 μg ml^{-1} EtBr. *b*, pBR322 DNA treated with Fr.4 enzyme was electrophoresed in the same way as for *a*. *c*, A mixture of pBR322 treated with Fr.5 enzyme and pAO3 treated with Fr.4 enzyme was analysed as described above.

Positively supercoiled topoisomers

To distinguish between the various possible conformations of DNA, the reaction product of Fr.4 was centrifuged in a CsCl equilibrium density gradient in the presence of ethidium bromide (EtBr) then each fraction was analysed by agarose gel electrophoresis. Figure 4*a* shows that pBR322 DNA incubated with Fr.4 enzyme formed a band of much heavier density than the relaxed form of pAO3 DNA[18] (prepared by Fr.5 enzyme) which was used as an internal marker, indicating that the former represented positively supercoiled DNA. The ladders at the peak position of pBR322 (Fig. 4*b*, lanes 2–4) coincided with a standard sample of positively supercoiled topoisomers (lane 5)[19] but not negatively supercoiled ones (lane 1).

Two-dimensional agarose gel electrophoresis[20] provides another means of distinguishing between positive and negative superhelical DNA topoisomers. After electrophoresis in the first dimension, gels were soaked in a mild concentration of EtBr and electrophoresed in the orthogonal direction. In the second dimension, positively supercoiled DNA had a higher mobility due to the increase in the superhelical density by EtBr, while the migration of negatively supercoiled DNA was retarded because EtBr relaxed it. Figure 5*a* shows clear separation of a control mixture of negatively and positively supercoiled DNA topoisomers in the second dimension, forming a symmetrical arch pattern. The reaction products of Fr.4 enzyme (Fig. 5*b*) migrated more rapidly in the second dimension, indicating that they were in fact positively supercoiled DNA. In Fig. 5*c*, a mixture of pAO3 incubated with Fr.4 enzyme and pBR322 treated with Fr.5 enzyme (a control for relaxed DNA at 75 °C) was developed by two-dimensional agarose gel electrophoresis. The pattern of pAO3 clearly showed the formation of positively supercoiled DNA topoisomers.

Superhelicity at high temperature

It should be noted that our reaction temperature was 75 °C and that the products were analysed at 24 °C. The superhelicity of DNA is known to be affected by temperature[19]. Thus, in the conditions of our analysis, the DNA would be less positively supercoiled, or more negatively supercoiled, than in the reaction mixture. The difference in superhelicity caused by temperature was roughly three superhelical turns per 20 °C in our system using pBR322 (data not shown). Note also that the fully relaxed pBR322 DNA formed by the topoisomerase in Fr.5 at 75 °C (see Table 1) appeared to be negatively supercoiled by five turns in our assay conditions. DNA must be more positively supercoiled by several turns in our reaction mixture at 75 °C than was actually observed at the ambient temperature.

Reverse gyrase—a novel enzyme?

The reverse gyrase studied here might consist of two components: a putative DNA-binding protein which introduces positive superhelical constraints, consequently creating negatively supercoiled domains in the unoccupied parts of closed circular DNA, and a topoisomerase which could relax these regions. The resulting DNA would then be positively supercoiled on removal of the binding proteins. This type of mechanism was excluded by the following two experiments.

First, the minimal protein concentration required for reverse gyrase activity (for this purpose, Fr.4 was further purified by hydroxylapatite chromatography) was estimated to be less than one-tenth the molar ratio of the substrate DNA (Fig. 3*d*). This amount of protein in the reaction mixture is insufficient to constitute a nucleosome-like complex, as DNA-binding proteins would be needed in a molar excess over the DNA. A preliminary analysis of protein components in this fraction by SDS-polyacrylamide gel electrophoresis revealed four major bands in equimolar amounts (molecular weights 124,000, 101,000, 45,000 and 42,000). Second, the linking number of DNA in the hypothetical protein–DNA complex should not be changed by adding exogenous topoisomerases as the DNA should be relaxed before deproteinization, while free positively supercoiled DNA should be a good substrate for the second topoisomerase. This notion was tested by further incubation of the reaction product of Fr.4 with Fr.5 enzyme at 75 °C or with yeast nicking–closing enzyme at 30 °C. Figure 3*c*, lanes 5–8 shows that the final products were relaxed DNAs, indicating that the positively supercoiled DNA was not complexed in the reaction mixture. Therefore, the Fr.4 activity was not due to a combination of DNA-binding proteins and a topoisomerase, but Fr.4 must contain the unique enzymatic activity of a reverse gyrase which produces DNA with positive superhelical tension.

In living organisms, no positively supercoiled DNA has ever been reported, nor has an enzyme been found to produce such a topological constraint. It is possible that positive supercoils are relaxed as soon as they are formed, by the potent type I topoisomerases generally found in eukaryotic cells. In *Sulfolobus*, type I topoisomerase activity was low compared with the three other topoisomerases (see Table 1), which may have been essential for our discovery of the novel reverse gyrase activity. Positively supercoiled DNA can be prepared *in vitro* by: (1) using intercalating drugs such as EtBr; (2) raising the temperature of a solution containing relaxed circular DNA prepared at a lower temperature; (3) binding large amounts of DNA gyrase to nicked DNA, then sealing it and removing the proteins[21]; (4) using stoichiometric amounts of DNA topoisomerase II'[22]; or (5) using netropsin and a DNA topoisomerase[23]. Here, we have shown that reverse gyrase can form positively supercoiled DNA by changing the linking number of closed circular DNA. The biological activity of such a DNA molecule is of great interest, as well as its physicochemical properties.

Compared with the extent of the positive superhelicity produced by intercalating pBR322 DNA with EtBr (more than 20 turns), the superhelicity produced by reverse gyrase appeared incomplete. We observed positively supercoiled DNA with eight turns in our gel analysis at 25 °C (see Fig. 3*c*, lane 7 and Fig. 4*b*, lane 3, for example), thus we estimate 13 positive superhelical turns at best in our reaction at 75 °C. There are two possible explanations for this: first, there is an upper limit to increasing the linking number of DNA because of some physical stress in the DNA helix itself. The positively supercoiled circles formed by netropsin binding, described above, represent the same situation[24]. Second, as the DNA becomes more positively supercoiled, so its ability to react with the enzyme might decrease.

Why is reverse gyrase needed?

Negatively supercoiled DNA is believed to be a favourable substrate for replication, transcription and recombination. Conversely, positively supercoiled DNA might be unfavourable for these functions. So what is the role of a topoisomerase which introduces positive superhelical strains into DNA? One trivial explanation is that because *Sulfolobus* grows at 75 °C, reverse gyrase is required to prevent the genomic DNA from denaturation by tightening the helical pitch of DNA (as the G+C content of *Sulfolobus* is only 40%). If this is the case, similar activities should exist in other thermophilic organisms, and their plasmids, if any[25]; no such examples have been reported.

We suggest, on the other hand, that reverse gyrase is distributed widely in many organisms to counteract the effects of other topoisomerases. It may actively alter the superhelicity of DNA so as to disassemble the stable complexes of proteins and negatively supercoiled DNA. For example, chromatin DNA is held in a stable complex with histones but it is believed that DNA must be freed from histones for replication, recombination, transcription, etc. To release the histones from nucleosomes it may be necessary to reverse the assembly process[26], in which positive superhelical turns have been removed by topoisomerases. Instead, the reverse gyrase could introduce positive superhelical turns into the internucleosomal regions and the resulting superhelical strain could detach the histones from the DNA.

A similar situation may prevail when cruciform structures or segments of Z-DNA[27] that are formed in the negatively supercoiled DNA[28,29] need to be reorganized to regular B-form DNA. Relaxing the negatively supercoiled DNA may not provide sufficient driving force to cause structural changes (probably because specific proteins must be associated) and here reverse gyrase may be needed. The transition of such structures in chromosomes may be important as initiation signals for DNA replication, recombination or gene expression[30,31].

We thank Drs H. Nash, T. Shibata, S. Higuchi, M. Gellert, P. Gray and Yoshiko Kikuchi for many critical suggestions and encouragement and for reading the manuscript; Drs T. Goto and J. Wang for providing the P4 phage kit; Dr A. Oka for plasmid pAO3; Dr W. Zillig for the pure RNA polymerase of *S. acidocaldarius* strain DSM639 and its antiserum; and Ms M. Yamashita for help in preparing the manuscript.

Use of light for footprinting DNA *in vivo*

Michael M. Becker* & James C. Wang

Department of Biochemistry and Molecular Biology, Harvard University, 7 Divinity Avenue, Cambridge, Massachusetts 02138, USA

A new 'photofootprinting' technique, which uses light to detect protein–DNA contacts as well as changes in the structure of DNA at the base pair level, has been developed and used to detect contacts between lac *repressor and the* lac *operator in* Escherichia coli *cells.*

ALTHOUGH it is well established that interactions between DNA and protein regulate gene expression, there are few techniques capable of directly probing these interactions *in vivo*. Given the complexity of the intracellular environment and our inability to reconstruct it, accurate molecular descriptions of gene regulation are critically dependent on the development of such techniques. Currently, experiments using DNase I 'footprinting'[1], chemical modification[2,3], bromouracil cross-linking[4] and drug cleavage[5,6] can probe, with high resolution, protein–DNA interactions *in vitro*. In each technique a protein is bound to a uniquely end-labelled DNA fragment. The complex is then subjected to an enzymatic, chemical or photochemical procedure which either breaks the DNA backbone directly or modifies the DNA in such a way that its backbone can be subsequently broken by alkali[7]. After removal of protein, the labelled DNA is denatured and electrophoresed in a polyacrylamide sequencing gel. An autoradiograph of this gel shows a pattern of end-labelled fragments which correspond to breaks in the DNA backbone induced by the modification or cleavage procedure. As cleavage rates may be altered by protein binding, corresponding changes in the strand breakage pattern may be used to identify protein contacts.

Although protein binding sites can be identified and characterized *in vitro* by these techniques, the chemical or enzymatic procedures used to induce strand cleavage are often too harsh and too slow to be used on living cells without perturbing native protein–DNA interactions. We report here the development of a new technique, termed 'photofootprinting', which uses light to probe protein–DNA interactions *in vitro* and *in vivo*. The technique, in its simplest form, is based on the observation that a small but significant distortion of the double helix is necessary to form a UV photoproduct[8–11]. If protein contacts affect the geometrical changes necessary for photoproduct formation, exposure of protein-free and protein-bound DNA to light followed by breakage of the DNA backbone only at the sites of photodamage will yield two different sets of DNA fragments. When analysed on a sequencing gel, differences in the strand-breakage pattern of these two DNAs will occur at those bases in contact with protein. More elaborate procedures based on photochemical reactions between DNA and small probes such as photosensitizers will be described below.

To detect protein–DNA contacts using light, we have developed a chemical procedure which exploits a common feature of photoreacted bases absent in unmodified bases so as to break the DNA backbone only at the sites of photodamage. In each of the known major photoproducts in DNA, one or more of the 5,6-double bonds of a pyrimidine becomes saturated on photoreaction[8,12]. As carbonyl groups conjugated to a double bond are poorly reduced by sodium borohydride[13], the carbonyl group at position 4 of photochemically modified thymines can be selectively reduced in the presence of other bases[14]. Furthermore, Kunieda and Witkop[15] and Miller and Cerutti[14,16], have shown that reduction of thymines saturated at the 5,6-position with excess $NaBH_4$ opens the thymine ring. As conjugation of the lone pair electrons of the glycosidic nitrogen at position 1 is greatly reduced by saturation of the 5,6-double bond and ring opening, the glycosidic bond of photochemically modified and reduced thymine should be much more labile to acid hydrolysis than unmodified thymine. Once the glycosidic bond is hydrolysed by acid, the phosphate backbone can be broken at the sugar ring by subsequent treatment with alkali[7]. In practice, base hydrolysis and subsequent breakage of the backbone can be carried out in one step by briefly heating in acidic aniline.

Although the 4 position of cytosine is not reduced by $NaBH_4$, saturation of the 5,6-double bond is known greatly to enhance spontaneous deamination of the 4 position, converting it to a carbonyl group[17]. Thus, like thymine, photochemically modified cytosine should be selectively reduced and its ring opened by $NaBH_4$, labilizing its glycosidic bond to acid hydrolysis and subsequent strand breakage.

Photofootprinting the *lac* repressor *in vitro*

To determine whether protein contacts can be detected with UV light alone, a 95-base pair (bp) fragment of DNA containing the *lac* operator[18] was exposed for 20 and 80 s to a 150-W xenon lamp in the presence and absence of *lac* repressor. After purification and after the DNA was end-labelled with ^{32}P, the photoproducts were labilized by the chemical degradation procedure and the resulting strand breakage pattern was analysed on a sequencing gel. In the absence of *lac* repressor, brief irradiation of the *lac* operator induced the formation of many photochemically modified bases which could be detected by the chemical degradation procedure (Fig. 1). Photoproducts were detected not only at pyrimidines but, unexpectedly, also at purines. Although photoreactions between adjacent pyrimidines are well documented[8], photoreactions between pyrimidines and purines are not[12], and further characterization is necessary to establish the identity of these new photoproducts.

When these experiments are repeated in the presence of *lac* repressor, repressor binding inhibited, and in some cases enhanced the ability of base pairs to undergo photochemical modification (Fig. 1). The location of the major repressor contacts is in excellent agreement with the repressor binding site detected by methylation protection[19], DNase I footprinting[20], bromouracil cross-linking[4] and chemical synthesis methods[21]. Thus, brief exposure of the *lac* repressor–*lac* operator complex to UV light can be used to identify repressor contacts.

In contrast to other techniques[19,20], UV light also detects repressor contacts upstream and downstream from the known repressor binding site. Although these weak 'contacts' could result from repressor-induced distortions in adjacent protein-free DNA, we believe them to represent previously unreported or unidentified repressor contacts (see below).

Figure 2 examines in detail the chemistry used to detect the *lac* repressor–*lac* operator photofootprint. Several features of this analysis are noteworthy. First, detection of a photofootprint requires both $NaBH_4$ reduction and acidic aniline cleavage. If either step is excluded, no cleavage of the DNA is observed (compare methods *d* and *e* and *b* and *c*). Second, in the absence of photodamage, cleavage of DNA by the $NaBH_4$–acidic aniline technique is very weak and comparable with the same background cleavage resulting from piperidine treatment (compare the first lanes of methods *a*, *b* and *e*). Thus, the background cleavage of the $NaBH_4$–acidic aniline technique is as low as the background cleavage observed in the chemical sequencing method of Maxam and Gilbert[7]. Third, in these conditions UV light does not directly cleave DNA (method *a*).

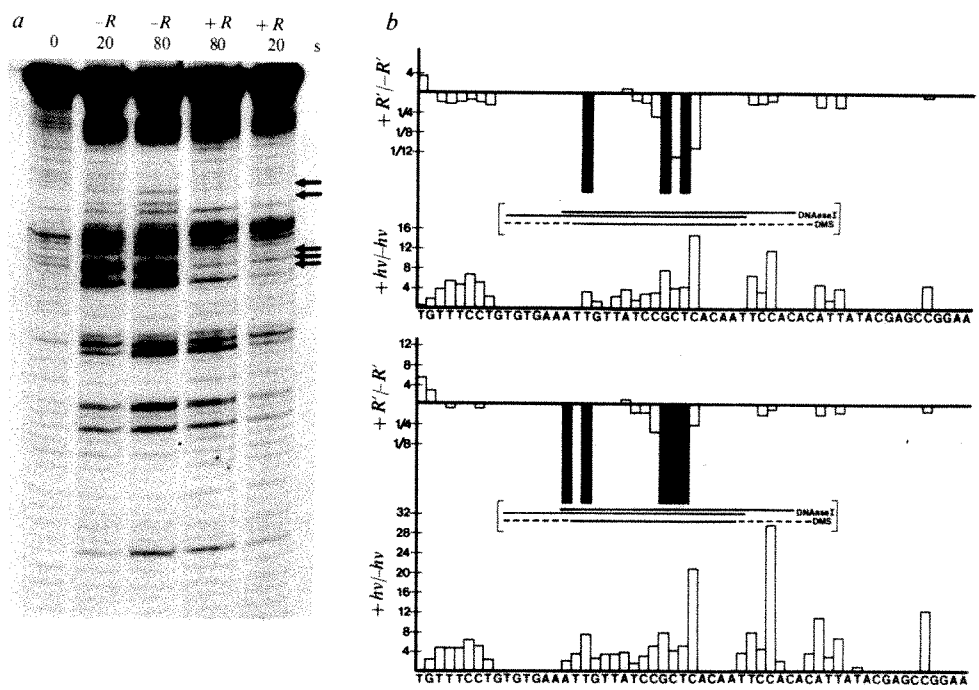

Fig. 1 *In vitro* photofootprints of the *lac* repressor bound to the *lac* operator. *a*, An autoradiogram of the *lac* repressor photofootprint. Lane 1, a no-light control showing the background resulting from the chemical labilization procedure. Lanes 2, 3, the effect of irradiating the *lac* operator for 20 and 80 s, respectively, in the absence of *lac* repressor. Lanes 4, 5, the effect of irradiating the *lac* operator for 80 and 20 s, respectively, in the presence of *lac* repressor. The level of photodamage in these experiments is very low: ~1 bp in 500 is damaged by light. Arrows denote bases whose photodamage is totally blocked by repressor binding. *b*, results of the autoradiogram quantified by microdensitometry and displayed as a histogram. The upper half summarizes the results of the 20-s irradiation experiment and the lower half those of the 80-s irradiation experiment. The effect of light on the cleavage of DNA in the absence of *lac* repressor is expressed as the ratio $(+h\nu/-h\nu)$, where $+h\nu$ is the cleavage of a base in the presence of light and $-h\nu$ is its cleavage in the absence of light. The effect of added *lac* repressor on light-induced cleavage of a base is expressed as the ratio $(+R'/-R')$ where $+R'$ is the light-induced cleavage of a base in the presence of *lac* repressor minus its cleavage in the absence of light and $-R'$ is the cleavage of the base in the absence of repressor minus its cleavage in the absence of light. When the value of $(+R'/-R')$ is $<1/20$, protein binding is considered to block photodamage totally and the corresponding position in the histogram is blackened. In brackets, that region of the *lac* operon protected by *lac* repressor from DNase I digestion is shown as a pair of lines[20]. The upper line summarizes the protection results for the same DNA strand analysed in the photofootprinting experiments and the lower line summarizes the results for the opposite strand. That region of the *lac* operator protected by *lac* repressor from DMS is shown below the DNase I results[19]. Strong protection is denoted by a continuous line and weak protection by a dashed line.

Methods: Irradiation was conducted with a 150-W xenon lamp (PRA model ALH215) equipped with an elliptical mirror. The output of the lamp consists of a focused beam 3 mm in diameter which is passed through a 10-cm long water filter to remove IR radiation before impinging on the sample. Samples were irradiated in 200 μl Micropets (Clay Adams) sealed at one end with a rubber septum. Although the Micropets absorb a small amount of UV radiation, similar results were obtained in UV-transparent cuvettes. In a typical experiment, 12 μl of a solution consisting of 10 mM Tris (*p*H 7.4), 10 mM $Mg(OAc)_2$, 10 mM KCl, 0.1 mM EDTA, 0.1 mM 2-mercaptoethanol, 12% glycerol, 100 μg ml^{-1} gelatin, 15 ng of a 95-bp *lac* operator fragment[18] and 0.1 μg of pBR322 plasmid DNA was irradiated in the absence or presence of 1.4 μg of *lac* repressor. 10 μg of carrier tRNA was then added to each sample and repressor removed by phenol extraction. The *Eco*RI end of the *lac* operator fragment was labelled with 25 μCi of [α-^{32}P]dATP using the Klenow fragment of *E. coli* DNA polymerase I and unreacted ATP was removed by dialysis against 2 M NaCl, 1 mM Tris (*p*H 7), followed by dialysis against 1 mM Tris (*p*H 7). The solutions were transferred to a 1.5-ml Eppendorf tube and heated at 50 °C for 5 h in 1 mM Tris (*p*H 7), 5 mM NaCl to effect deamination of photochemically modified cytosines. After precipitation from ethanol, each sample was dissolved in 50 μl of 5 mM KP_i (*p*H 8.3), 5 mM NaCl containing 50 mM thymidine and cooled to 0 °C. 50 μl of the same KP_i/NaCl/thymidine solution containing 1 mg of freshly dissolved sodium borohydride was then added. The samples were briefly vortexed and allowed to stand unagitated and open to the air at 2 °C in the dark. Thymidine is present during the reduction step to react with any borane generated by the decomposition of $NaBH_4$ in water. Otherwise, borane, which preferentially reduces carbonyl groups conjugated to double bonds, would reduce those bases that are not damaged by light. The reactions were stopped after 15 h by adding 250 μl of 0.7 mM NaOAc–HOAc (*p*H 5.0) and allowed to stand at room temperature for 1 h with occasional vortexing. After precipitating the DNA from 750 μl of ethanol the dried and rinsed pellets were redissolved in 170 μl of 0.5 M NaOAC–HOAc (*p*H 5.0). Following incubation at room temperature for 1 h with occasional vortexing, 100 μl of water and 750 μl of ethanol were added to precipitate the DNA. The rinsed and dried DNA pellets were then dissolved in 2 μl of water and 25 μl of 1.0 M aniline–HOAc (*p*H 4.5) was added[39,40]. After heating at 60 °C for 20 min in the dark, the samples were frozen at −78 °C and lyophilized under high vacuum. Freezing and lyophilization from 25 μl of water was repeated three more times and the DNA twice from ethanol. Following rinsing and drying of the DNA pellet, the samples were dissolved in 98% deionized formamide, boiled for 3 min and electrophoresed on a 20% polyacrylamide sequencing gel at 1,500 V for 14 h.

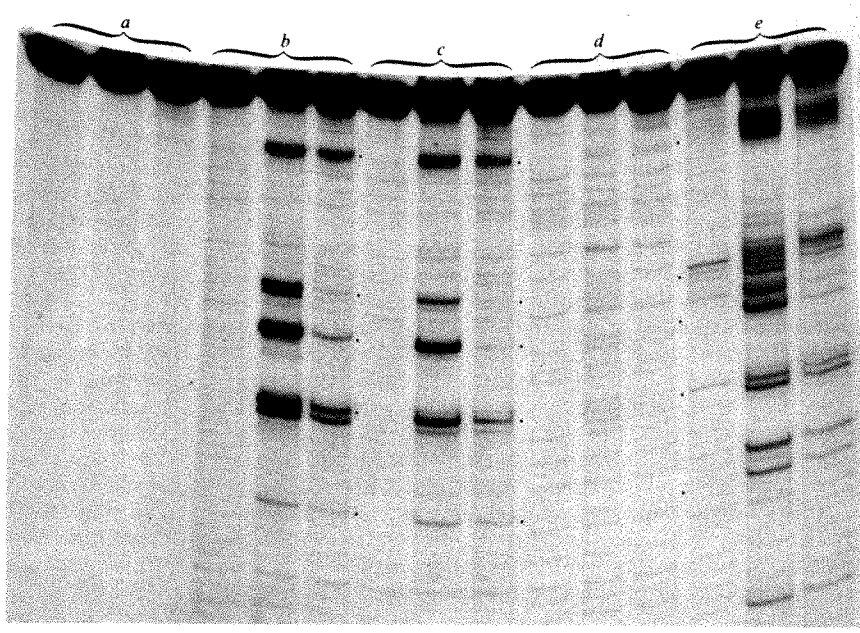

Fig. 2 *In vitro* photofootprints of the *lac* repressor bound to the *lac* operator detected by different chemical treatments (*a*–*e*). For each chemical treatment, three lanes are shown. The first lane of each set is a no-light control, the second lane shows the effect of irradiating the *lac* operator for 40 s in the absence of *lac* repressor and the third lane shows the effect of irradiating the *lac* operator for 40 s in the presence of *lac* repressor. *a*, No chemical treatment; *b*, cleavage is induced by heating in piperidine; *c*, cleavage is induced by successively deaminating, reducing with $NaBH_4$ and heating in piperidine; *d*, cleavage is induced by successively deaminating and heating in acidic aniline; *e*, cleavage is induced by successively deaminating, reducing with $NaBH_4$ and cleaving with acidic aniline.

Methods: DNA was cleaved with piperidine by dissolving the DNA in 100 μl of freshly diluted 1 M piperidine and heating at 90 °C for 25 min[7].

All other methods are identical to Fig. 1.

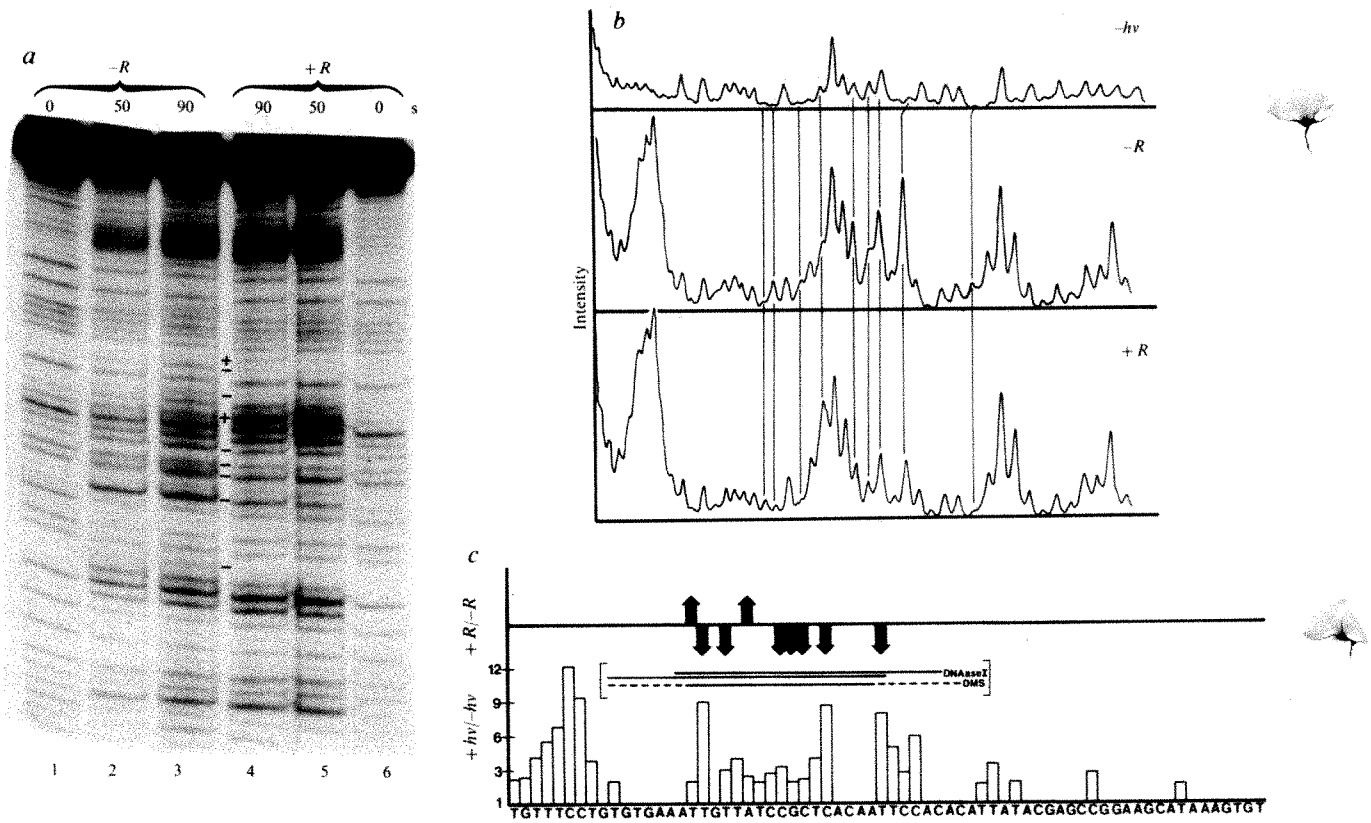

Fig. 3 Photofootprints of the *lac* repressor bound to the *lac* operator *in vivo*. *a*, An autoradiogram of the *lac* repressor photofootprint obtained *in vivo*. Lanes 1–3, the effect of irradiating *E. coli* cells containing the *lac* operator plasmid unbound by *lac* repressor for 0, 50 and 90 s. Lanes 4–6, the effect of irradiating *E. coli* cells containing the *lac* operator plasmid bound by repressor for 90, 50 and 0 s, respectively. *b*, Microdensitometer scans of the 90-s irradiation experiment. The upper portion is the no-light control (lane 6 of *a*; similar results are also observed in lane 1). The middle and lower portions show the effect of irradiating the *lac* operator plasmid in the absence and presence of bound repressor, respectively (lanes 3, 4). *c*, The microdensitometer scans quantified and displayed as a histogram. The effect of light on the cleavage of DNA in the absence of *lac* repressor is expressed as the ratio $(+h\nu/-h\nu)$ while the effect of repressor on light-induced cleavage of DNA is denoted either as an enhancement (↑) or blockage (↓) of cleavage.

Methods: Competent *E. coli* cells lacking a chromosomal copy of the *lac* structural gene (*E. coli* strain E7074 F'lacIProA$^+$, B$^+$Δ(*lac pro*) *sup E thi* (kindly provided by Dr J. Beckwith) were transformed with either plasmid pJW231 or pJW280 (see text for explanation). 900 μl of *E. coli* cells bearing either plasmid were grown to saturation in LB, pelleted and resuspended in 450 μl of M9 buffer[41]. The cells were then placed on ice and photolysed in 150-μl aliquots in a quartz microcuvette. Following irradiation, each aliquot was immediately frozen and stored at −78 °C. The aliquots were combined, pelleted and plasmid DNA isolated by an alkaline-SDS miniprep[42]. After phenol extraction from 1% SDS, the DNA was ethanol precipitated, restricted with *Eco*RI and labelled with [α-^{32}P]dATP using the Klenow fragment of *E. coli* DNA polymerase I. Unreacted ATP was removed by dialysis against 2 M NaCl, 1 mM Tris (*p*H 7), followed by dialysis against 1 mM Tris (*p*H 7). The DNA was then restricted with *Bam*HI, ethanol precipitated and the 95-bp *lac* operator fragment purified by electrophoresis on a 6% polyacrylamide gel. After extraction from the gel and ethanol precipitation, the DNA was processed and analysed as described in Fig. 1 legend.

Although the $NaBH_4$–acidic aniline technique can be used to break the DNA backbone at the sites of photodamage, the efficiency with which the photoproducts are detected is unknown. To estimate this efficiency, a second cleavage technique has been used to labilize the *lac* repressor–*lac* operator photofootprint described in Fig. 1. As shown by others, when UV-irradiated DNA is heated in piperidine the DNA backbone is cleaved quantitatively at the so-called PydC photoproducts[23]. These photoproducts occur at T-C, C-C and to a much lesser extent T-T dinucleotide residues and result from a cyclo-addition reaction between the 5,6-double bond of one pyrimidine and the carbonyl group of thymine or the imino tautomer of cytosine of an adjacent pyrimidine. Because these photoproducts contain a pyrimidine saturated at its 5,6-double bond, their formation can be detected by the $NaBH_4$–acidic aniline cleavage technique outlined here. As Fig. 2 shows, cleavage of the PydC photoproducts by the $NaBH_4$–acidic aniline technique is comparable with the quantitative cleavage of these sites by piperidine (compare methods *b* and *e*). Although these measurements do not indicate the efficiency with which other photoproducts are cleaved by the $NaBH_4$–acidic aniline technique, the structural similarities between the PydC photoproducts and the well known pyrimidine dimers, pyrimidine trimers and spore product suggest that these latter photoproducts[8] will also be readily labilized by this technique.

Photofootprinting the *lac* repressor *in vivo*

Having demonstrated the feasibility of footprinting a protein *in vitro* with light, we next investigated the possibility of footprinting *in vivo* with light. Two derivatives of the plasmid pBR322 have been constructed for this purpose. The first, designated pJW231, contains a copy of the same 95-bp *lac* operator fragment used in the *in vitro* experiments[24]. The second, designated pJW280, contains this *lac* operator plus an 1,100-bp fragment containing the *lac* repressor structural gene under control of an I^q promoter. When *Escherichia coli* cells lacking a chromosomal copy of the *lac* repressor structural gene are transformed separately with these plasmids, two cell types result. *E. coli* cells bearing the pJW231 plasmid contain *lac* operators unbound by *lac* repressor whereas *E. coli* cells bearing the pJW280 plasmid contain *lac* operators bound by *lac* repressor. Following brief irradiation of both cells, plasmid DNA is isolated free of chromosomal DNA. The 95-bp *lac* operator fragment is excised from each plasmid by restriction with *Eco*RI and *Bam*HI, end-labelled with ^{32}P and the photoproducts chemically labilized. The photofootprint of the *lac* repressor is then revealed by denaturing the DNA from both plasmids and comparing their strand breakage pattern on sequencing gels. As shown in Fig. 3, the binding of *lac* repressor *in vivo* enhances the formation of two photoproducts and inhibits the formation of seven others.

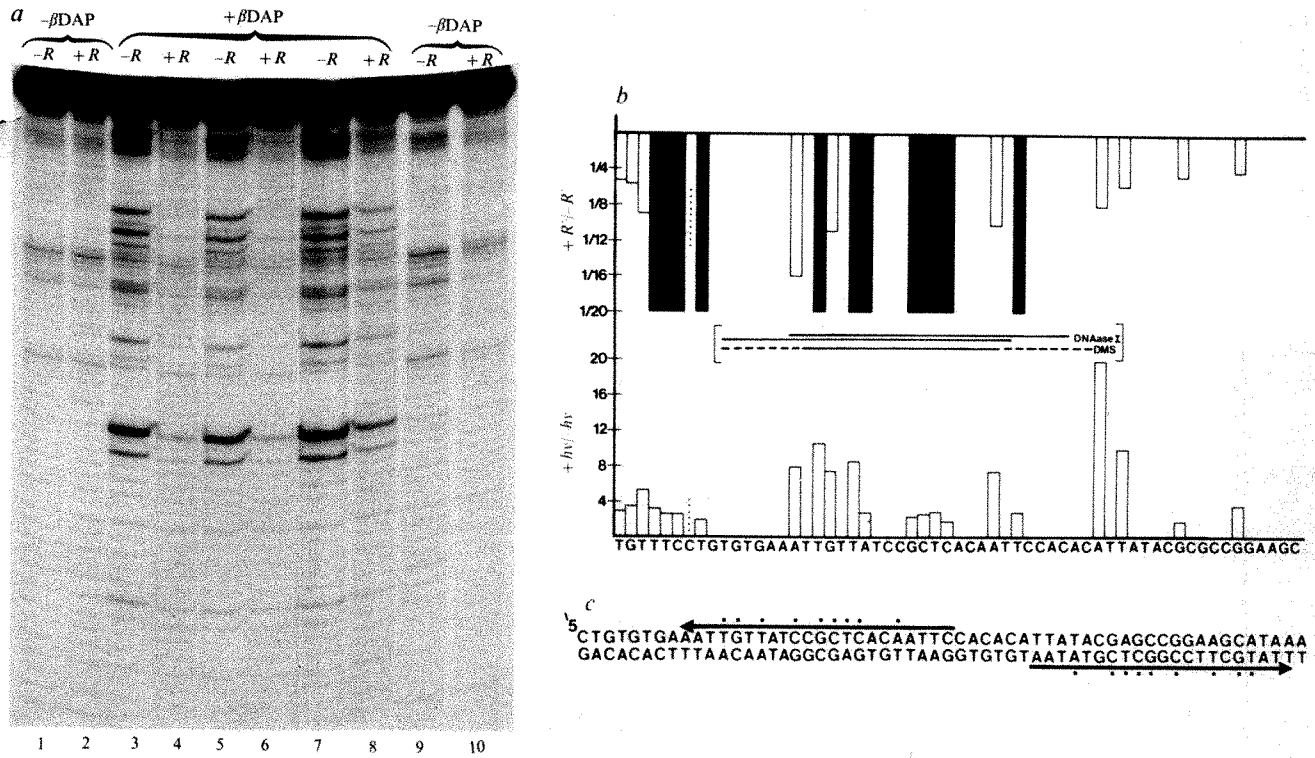

Fig. 4 Photofootprints of the *lac* repressor obtained *in vitro* with a triplet sensitizer. *a*, An autoradiogram of the *lac* repressor–*lac* operator photofootprint. Lanes 1, 2, the effect of a 30-min irradiation of the *lac* operator at 315 nm in the absence of sensitizer. Lane 1 contains no *lac* repressor while lane 2 contains *lac* repressor. Lanes 3–8, the effects of irradiating the *lac* operator with 315 nm light in the presence of 10 mM sensitizer (β-dimethylaminopropiophenone, Aldrich). Irradiation was for 30 min (lanes 3, 4; similar results were obtained in 5 min), 60 min (lanes 5, 6) or 120 min (lanes 7, 8). Odd-numbered lanes contain no *lac* repressor while even-numbered lanes contain *lac* repressor. Lanes 9, 10, the effect of a 120-min irradiation on the *lac* operator at 315 nm in the absence of sensitizer. Lane 9 contains no *lac* repressor while lane 10 contains repressor. *b*, Results of the autoradiogram quantified by microdensitometry and displayed as a histogram. The cleavage of DNA by sensitizer in the absence of *lac* repressor is expressed as the ratio $(+h\nu/-h\nu)$ while the effect of *lac* repressor on sensitizer-induced cleavage is expressed as the ratio $(+R'/-R')$ (see Fig. 1 for nomenclature). A base whose cleavage could not be accurately quantified by microdensitometry is denoted by a dotted line. Fading of the photofootprint at long irradiation times is probably due to damage of the complex by the 315 nm light. *c*, The plausible pseudooperator site. Homologous bases are denoted by a dot.
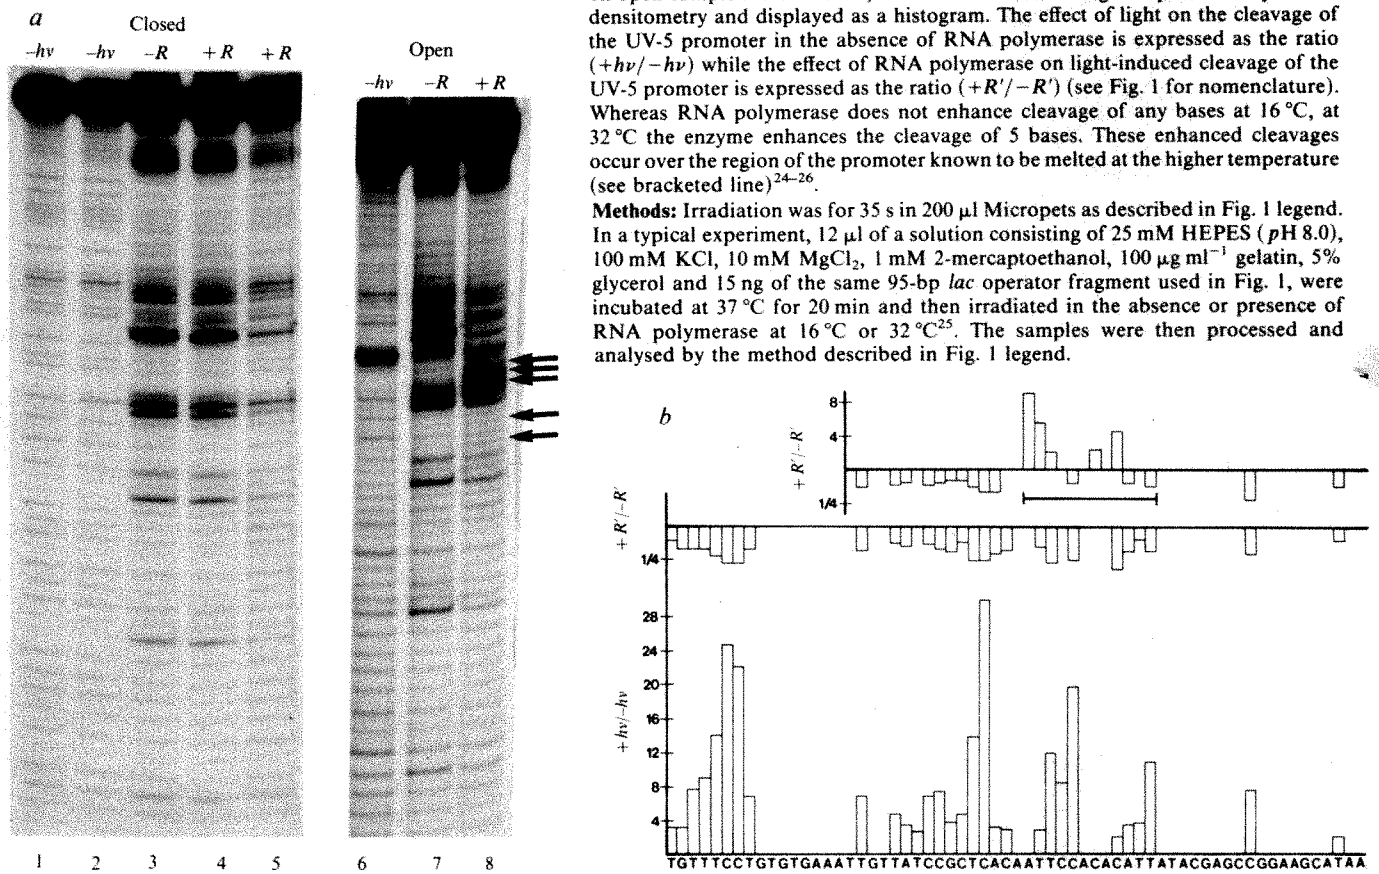
Methods: Irradiation was with the same apparatus as described for Fig. 1 except that a monochromator (Instruments SA, Inc., Model 1200-UV-H10) was placed between the water filter and the sample. The monochromator entrance and exit sites were 2 mm (15 nm bandwidth). The experimental conditions and reagents were the same as for Fig. 1.

The *lac* repressor binding site detected in these measurements agrees well with the *in vitro* photofootprinting results as well as with the *in vitro* results obtained by other techniques[19–21]. Thus, contacts between the *lac* repressor and its operator can readily be detected *in vivo* with light.

A triplet sensitizer and psoralen

Although light alone can be used to detect *lac* repressor and, as shown below, RNA polymerase binding, less tightly associated proteins might go undetected. We have therefore sought to develop additional photochemical techniques which may be more sensitive to these types of protein–DNA interactions. Two such techniques have been developed. In the first, a triplet sensitizer, β-dimethylaminopropiophenone (βDAP) is used to excite DNA indirectly. As demonstrated previously, when excited by 315 nm light *in vivo*, βDAP can transfer its excitation energy to DNA, causing the DNA to assume an excited triplet state[25]. Because this triplet state yields many of the same photoproducts formed by direct UV irradiation of DNA, the chemical labilization procedure outlined here can be used to detect βDAP-induced photolesions. The major advantage of using a sensitizer to introduce photolesions into DNA is the requirement of a collision between sensitizer and DNA before the sensitizer can transfer its excitation energy to DNA[26]. Thus, photoproduct formation induced by βDAP is expected to be more sensitive to protein binding than direct irradiation by UV light.



To test these hypotheses, the same *lac* repressor–*lac* operator experiment described in Fig. 1 was repeated using 315 nm light to excite the sensitizer. As shown in Fig. 4, in the absence of sensitizer, DNA is undamaged by 315 nm radiation, but in the presence of sensitizer, irradiation introduces a larger number of photoproducts into the DNA. When these experiments are repeated in the presence of *lac* repressor, repressor binding strongly inhibits the formation of many of the βDAP-sensitized photoreactions.

The *lac* repressor photofootprint obtained with βDAP exhibits many of the same features observed by other techniques. For example, that region of the operator strongly footprinted by bromouracil cross-linking[4], DNase I digestion[20] and dimethyl sulphate (DMS)[19] is also strongly protected from βDAP-induced cleavage. However, in contrast to these measurements, βDAP also detects *lac* repressor contacts outside the presumed operator. Strong contacts are observed downstream from the operator while weaker ones are detected upstream. Although strong contacts downstream are not detected by bromouracil cross-linking or DMS experiments, reexamination of the DNase I results[20] reveals that *lac* repressor both enhances and inhibits DNase I cleavages in this region. As photofootprinting with UV light also detects repressor contacts in this region (see Fig. 1), strong inhibition of sensitizer-induced cleavage in this area probably results from repressor contacts that are insensitive to bromouracil cross-linking or DMS protection experiments.

Weak contacts detected upstream from the presumed *lac* operator with βDAP are also detected by direct irradiation with UV light (see Fig. 1). Because some of these cleavages occur well upstream of the presumed operator, we have examined the sequence of this area for the possibility of a second or pseudo-operator binding site. As shown in Fig. 4, we indeed found a

Fig. 5 *In vivo* photofootprints of *E. coli* RNA polymerase bound to the *lac* UV-5 promoter in a closed and open complex. *a*, An autoradiogram of the RNA polymerase photofootprint. Lanes 1–5, photofootprints of the closed RNA polymerase complex; lanes 6–8, photofootprints of the open RNA polymerase complex. Lanes 1 and 2 are no light controls. Lane 1 contains no RNA polymerase whereas lane 2 contains 100 nM RNA polymerase. Lane 3 shows the effect of irradiating the UV-5 promoter at 16 °C in the absence of RNA polymerase. Lanes 4 and 5 show the effect of irradiating the UV-5 promoter at 16 °C in the presence of 50 and 100 nM RNA polymerase, respectively. Lane 6 is a no-light control for the open complex. The dark band approximately one-third of the way down from the top of the gel is a contaminating *Eco*RI* band present in this preparation of DNA. It results from overdigesting the plasmid pJW231 with *Eco*RI and *Bam*HI to liberate the desired 95-bp UV-5 promoter fragment used in these photofootprinting experiments. Lane 7 shows the effect of irradiating the UV-5 promoter at 32 °C in the absence of RNA polymerase. Lane 8 shows the effect of irradiating the UV-5 promoter at 32 °C in the presence of 100 nM RNA polymerase. Arrows indicate the 5 bases showing the enhanced photoreactivity on open complex formation. *b*, Results of the autoradiogram quantified by microdensitometry and displayed as a histogram. The effect of light on the cleavage of the UV-5 promoter in the absence of RNA polymerase is expressed as the ratio $(+h\nu/-h\nu)$ while the effect of RNA polymerase on light-induced cleavage of the UV-5 promoter is expressed as the ratio $(+R'/-R')$ (see Fig. 1 for nomenclature). Whereas RNA polymerase does not enhance cleavage of any bases at 16 °C, at 32 °C the enzyme enhances the cleavage of 5 bases. These enhanced cleavages occur over the region of the promoter known to be melted at the higher temperature (see bracketed line)[24–26].

Methods: Irradiation was for 35 s in 200 μl Micropets as described in Fig. 1 legend. In a typical experiment, 12 μl of a solution consisting of 25 mM HEPES (*p*H 8.0), 100 mM KCl, 10 mM $MgCl_2$, 1 mM 2-mercaptoethanol, 100 μg ml^{-1} gelatin, 5% glycerol and 15 ng of the same 95-bp *lac* operator fragment used in Fig. 1, were incubated at 37 °C for 20 min and then irradiated in the absence or presence of RNA polymerase at 16 °C or 32 °C[25]. The samples were then processed and analysed by the method described in Fig. 1 legend.

second potential operator sequence, identical with the known *lac* operator at 9 bases. The observed 9-bp homology makes this site a reasonable candidate for repressor binding because a known repressor binding site, just upstream from the 'cap' binding site of the *lac* operon, also exhibits a 9-bp homology with the *lac* operator[27]. Binding studies of the *lac* repressor to a restriction fragment bearing both of these 9-bp operator sequences plus the known *lac* operator shows the formation of three strong complexes with relative affinities of 1, 1/200 and 1/800 (ref. 28). Although these measurements did not locate the weakest binding site, the affinity observed for this site is compatible with binding at the proposed site in Fig. 4, as the other 9-bp operator binding site exhibits only a fourfold greater affinity.

Although repressor binding at the proposed pseudo-operator sequence in Fig. 4 was not reported in DNase I protection experiments[20], reexamination of these results does reveal weak protection in this area. The failure of bromouracil cross-linking and DMS protection experiments to detect this repressor binding site may be due to the fact that a restriction fragment bearing only one-half of this operator was used in those experiments.

A second small organic molecule examined for its potential to footprint DNA photochemically is the well known intercalator psoralen. When excited by 350 nm radiation, psoralen covalently binds to DNA[29,30]. Because covalent addition saturates the 5,6-double bond of pyrimidines[31], the chemical labilization procedures used to detect UV and sensitizer-induced photoproducts can also be used to detect psoralen binding. A major advantage of using psoralen is its known sensitivity to nucleosome binding. Previous studies have shown that *in vivo* psoralen does not photoreact with nucleosome-bound DNA.[32,33] We have determined that psoralen binding can be detected at the base pair level using the chemical degradation procedure and that such binding is sensitive to *lac* repressor binding. Experiments are being conducted to determine whether nucleosome binding can be detected with psoralen, UV light and βDAP.

Photofootprinting structural changes in DNA

Previous measurements have shown that UV-induced damage to DNA may be enhanced by structural changes in the DNA. For example, pyrimidine dimer formation is enhanced in single- versus double-stranded DNA[8]; apparently, geometrical changes necessary for dimer formation are easier in single-stranded DNA. We have examined the separation of DNA strands by RNA polymerase to establish whether light can be used to footprint structural changes in DNA.

At low temperatures, *E. coli* RNA polymerase forms a closed complex at promotors[23]. When the temperature of this complex is raised, a short stretch of DNA is unpaired by RNA polymerase, resulting in the formation of a transcriptionally active open complex[34–37]. Photofootprinting of both the open and closed complexes of RNA polymerase bound to the *lac* UV-5 promotor revealed that the formation of both complexes can readily be detected with UV light (Fig. 5), binding being characterized by reductions in photoproduct formation throughout the promoter. However, whereas the closed complex does not enhance the photoreactivity of any bases, the open complex

enhances the formation of five photoproducts. The location of these five enhanced photolesions is in excellent agreement with the known site of DNA strand separation determined by other measurements[35–37]. Thus, a small structural change in DNA, such as its unpairing by RNA polymerase, can readily be detected at the base pair level by light.

Conclusions

The photochemical approaches used in these experiments to footprint DNA have several advantages over other methods. First, since light readily permeates cells, DNA can be footprinted *in vivo*. Indeed, when combined with the procedure of sequencing genomic DNA directly by indirect end-labelling[38], it should be possible to footprint almost any gene *in vivo* with light. Second, because the footprinting reaction is directly coupled to the absorption of light, it can be initiated essentially instantaneously and terminated within 10^{-9} to 10^{-6} s (the lifetime of the excited state). Thus, by using more powerful light sources it should be possible to footprint, kinetically, structural changes in DNA as well as protein movement along the DNA. Third, because the quantum yield of a photochemical reaction is relatively insensitive to changes in temperature or solvent, footprints of DNA can be obtained in a wide range of conditions. Fourth, because the chemical procedure developed to labilize DNA photoproducts is also expected to work on RNA, it should be possible to photofootprint RNA as well as DNA.

Search for excess cosmic-ray events from the galactic plane

R. W. Clay, R. J. Protheroe & P. R. Gerhardy*

Physics Department, University of Adelaide, Adelaide, South Australia 5001, Australia

Wdowczyk and Wolfendale[1] have recently suggested that the cosmic-ray beam at 10^{15}–10^{16} eV may contain a significant flux of γ rays from the direction of the galactic plane, and that this flux may affect the measured all-particle anisotropy and energy spectrum at these energies. We have searched for an excess of cosmic-ray events from the direction of the galactic plane. We can set upper limits which are close to the flux predicted by Wdowczyk and Wolfendale for the full galactic plane, and also for regions around the galactic centre. We have used these upper limits to place limits on the apparent brightness distribution of galactic γ-ray sources above 10^{15} eV, and on any contribution these sources can make to the cosmic-ray energy spectrum at the highest energies.

Recent observations using extensive air shower techniques have provided evidence for galactic sources[2–6], and possibly extragalactic sources[7], capable of producing γ rays with ultra high energies (10^{15}–10^{16} eV). Wdowczyk and Wolfendale[1] have examined the possibility that such galactic γ rays might be responsible for structure found in the cosmic-ray energy spectrum and anisotropy at these energies, and concluded that there is some experimental evidence for this. No individual datum is conclusive but the cited evidence suggests that γ rays may be responsible for 1% of cosmic ray showers from the direction of the galactic plane ($|b| < 10°$), and a rather larger fraction from near the galactic centre. This would constitute ~0.2% of the primary cosmic radiation.

We have used data from 3yr of operation of the University of Adelaide extensive air shower array at Buckland Park[8] (1.3×10^5 events with a mean energy of $\sim 5 \times 10^{15}$ eV) to search for any excess from the galactic plane. We summed all events observed with galactic latitude ($|b|$) below ~10° and compared this sum with that expected on the basis of events observed outside the galactic plane but at similar declinations. The data from Buckland Park are presented in Table 1 together with data from three other experiments[9–11] operating in a similar energy range. This then gives a full, though non-uniform, coverage of the galactic plane. The data from the experiments by Clark[9] and Chitnis *et al.*[10] were extracted from published celestial intensity maps. The data from Haverah Park were obtained with their 50-m system and were extracted from ref. 11. In the latter cases, the original investigators have presented their own null results for $|b| < 20°$ (ref. 9), $|b| < 10°$ (ref. 10) and $|b| < 5°$ (refs 11, 12). The Haverah Park and MIT experiments observed essentially the same region of sky. Data from these two experiments have been combined and are also shown in Table 1, clearly there is no evidence for there being any enhancement for $|b| \leqslant 10°$.

In estimating any upper limits to a γ-ray contribution from the galactic plane, one must take into account the statistical uncertainty in the cosmic-ray background estimation[13]. This depends on the total number of events used to estimate the background. The ratio, α, of the estimated background counts for $|b| \leqslant 10°$ to the total number of events with $|b| \geqslant 10°$ which were used to estimate the background is given in Table 1 for each experiment. Recently, Protheroe[14] has derived 95% (~1.65 s.d.) upper limits to the ratio of the source contribution to the background contribution given various observed counts,

84% and 95% confidence upper limits are given for the ratio of γ-ray flux to cosmic-ray flux.

estimated background, and α values. The procedure involved estimating the joint probability density function of the true background having some value and the ratio of source contribution and background having some value, and is described fully in ref. 14. The 95% confidence upper limit to the ratio of γ-ray contribution to cosmic-ray contribution for $|b| \leqslant 10°$ has been calculated for each experiment using this procedure and is given in Table 1 which also shows, 84% (~1 s.d.) upper limits calculated in the same way. Only the Haverah Park data have a 95% confidence upper limit to a galactic plane γ-ray contribution which is below ~1% of the cosmic-ray contribution.

By taking the lowest upper limit from the experiments which cover a particular region of the galactic plane and integrating over galactic longitude, we can obtain an estimate of the upper limit to any γ-ray enhancement for the galactic plane as a whole. Doing this, we obtain an 84% confidence upper limit of ~0.9%, and a 95% confidence upper limit of ~1.3%, for any γ-ray enhancement from the whole galactic plane ($|b| \leqslant 10°$). These upper limits are close to the ~1% enhancement predicted by Wdowczyk and Wolfendale[1].

The galactic centre passes almost overhead at Adelaide. We have used our data to search for any enhancement from the galactic plane within 60° of the galactic centre. It is possible that the galactic centre has a more localized excess and we have also examined events from the direction of the galactic centre (within ~10°). The results are also given in Table 1 together with the upper limits we derive for any γ-ray enhancement from these regions of the sky. The data show no significant enhancement over the expected background. Again, however, the 95% upper limits are very close to the flux predicted by Wdowczyk and Wolfendale[1].

At 10^{15}–10^{16} eV, the overall cosmic-ray anisotropy has a first harmonic amplitude of ~0.3% (ref. 1). Our limits on any excess flux from the galactic plane appear to preclude the possibility that such a high amplitude for a whole sky anisotropy could result solely from galactic γ rays.

There is no doubt that an excess of γ-ray events should exist from the galactic plane due to known galactic ultra high energy γ-ray sources. None of these sources has, however, been associated with large numbers of γ rays arriving at the Earth. The γ-ray sources which have been observed each contribute ~0.1% of the total cosmic ray events detected from the galactic plane by each experiment. Our 95% confidence upper limit of 1.3% for the total γ-ray excess from the galactic plane thus corresponds to only ~40 times the observed flux from a single known source.

Cygnus X-3 (refs 2, 3) is one of the brightest and also the most distant of the known galactic sources, being at a distance of the order of the galactic radius. This suggests that a simple disk population brightness, S, distribution (that is $N(>S) \propto S^{-1}$) is unlikely to be valid, and that instead the distribution of observed fluxes reflects the (unknown) γ-ray luminosity function of the sources.

Cygnus X-3 is not in the direction of the galactic centre. Neither are the Crab pulsar[5,6] and Vela X-1 (ref. 4), the other galactic ultra high energy candidate sources. Our upper limits on the inner galaxy flux ($|b| < 10°$, $|l| < 60°$) will not allow an enhancement above the total flux of outer galaxy sources such as is found for X rays $(9.4\times)$[15] or γ rays above 100 MeV $(2.2\times)$[15] even if these three sources were the only sources contributing to the 10^{15}–10^{16} eV γ-ray flux from the outer galaxy.

We note that if the total flux of γ rays were lower by about 10 times than that postulated by Wdowczyk and Wolfendale (it cannot be much lower than this on the basis of known sources) and their spectrum extends to $\geqslant 10^{19}$ eV, these events would distort the observed cosmic ray spectrum and produce a flattening at $\sim 10^{18}$ eV. With some steepening in the γ-ray spectrum above 10^{16} eV they would instead produce an 'ankle' in the cosmic ray spectrum as observed[16] at 10^{19} eV. It may then not be necessary to postulate a sharp cutoff to the γ-ray spectrum at 10^{17}–10^{18} eV which Wdowczyk and Wolfendale[1] needed to avoid gross disagreement with the observed cosmic-ray spectrum. Support for this suggestion may be found in data for energies above 10^{19} eV presented by the Sydney group[17]. These data show an excess from the galactic plane for showers with energies above 4×10^{19} eV (six events are observed for $|b| < 10°$ where we expect 1.0 ± 0.5). In this case, the Sydney detectors would be predominantly detecting muons from photoproduced pions[18–19]. At these energies the flux of such muons is expected to be quite significant for γ-ray initiated showers.

We have set a 95% confidence upper limit of 1.3% for any enhancement by γ rays of the 10^{15}–10^{16} eV cosmic ray flux from the galactic plane. This sets a limit to the total flux of ultra high energy galactic γ rays at ~40 times that observed from Cygnus X-3. Cygnus X-3 must then be amongst the brightest sources of such γ rays in our galaxy. These γ rays may be responsible for the ankle in the cosmic-ray energy spectrum above 10^{19} eV.

This work was supported by the Australian Research Grants Committee. We thank Dr J. Lloyd-Evans for permission to use unpublished data from his thesis.

Radio wave scattering in the galactic disk

J. M. Cordes*, S. Ananthakrishnan† & Brian Dennison‡

Electron density turbulence in the Galaxy causes radio sources to be broadened angularly by amounts that depend strongly on the direction of the source. Recent scattering measurements using very long baseline interferometry (VLBI)[1] and interplanetary scintillations (IPS)[2] of extragalactic sources, and interstellar scintillations (ISS) of pulsars[3] are used here to constrain the distribution of scattering material in the Galaxy. Although ubiquitous, scattering material appears to be highly concentrated in a thin disk of ~100 pc thickness and in clumps of 1–10 pc size probably associated with H II regions, stellar wind bubbles, and/or supernova shocks. Typical transverse velocities of scattering material are much smaller than typical pulsar velocities. We predict the scattering angle as a function of galactic latitude. The results imply a maximum observable surface brightness for incoherent sources of electron synchrotron radiation.

Recent work has demonstrated that electron density fluctuations on length scales of 10^9–10^{11} cm conform to a power law wavenumber spectrum of the form $C_n^2 q^{-\alpha}$ with $\alpha = 3.6 \pm 0.2$ (refs 3–6) where q is the wavenumber. This form of the spectrum is consistent with detailed measurements on a few lines-of-sight. Less detailed measurements on others sometimes suggest different values of α (refs 3, 7). We adopt a specific value ($\alpha = 11/3$) in the analysis below which is in agreement with the best studied lines-of-sight. Variations of α with direction will not grossly modify any of our calculations. There is some evidence that the spectrum extends over six or more decades in wavenumber, q (ref. 6). Although the slope of the spectrum shows little variation, the level of turbulence C_n^2 varies by at least four decades, both in going from high to low galactic latitudes and between lines-of-sight confined to the galactic disk[3].

We now use scattering and scintillation observables to constrain further the distribution of scattering material in the Galaxy and to provide a model for the observed scattering disk size as a function of galactic coordinates. VLBI measurements determine the scattering angle θ_{ISS} (FWHM) directly. IPS yields angular sizes by comparing the scintillation power spectrum of a source seen through the interplanetary medium with that of a point calibrating source at the same solar elongation. Interstellar scintillations of pulsars are parameterized by the scintillation bandwidth Δf_{ISS} and scintillation fluctuation time Δt_{ISS} (both half widths at half maxima of the two-dimensional intensity correlation function). The scattering angle for a plane-wave source is[3,8] (with C_n^2 in units of $m^{-20/3}$)

$$\theta_{ISS} \approx 0.133 \, (L_{kpc} \langle C_n^2 \rangle)^{3/5} f_{GHz}^{-11/5} \quad \text{arc s} \qquad (1)$$

where L is the effective path length in kpc, f is the observation frequency in GHz, and $\langle\ \rangle$ denotes average over path length. The wavenumber that contributes most to the scattering of a given source (if all turbulence were confined to a thin layer at distance $L/2$) is $q_{eff} \approx 2\pi\theta_{ISS}/\lambda$. Relative motion of source, turbulence and observer causes time variations with an effective velocity.

$$V_{ISS} \approx 10^{4.4} (L_{kpc} \Delta f_{ISS})^{1/2} / \Delta t_{ISS} f_{GHz} \quad \text{km s}^{-1} \qquad (2)$$

(Δf_{ISS} in MHz) which has been shown to correlate at the 66% level with pulsar velocities obtained interferometrically[9]. Consequently it appears that V_{ISS} is dominated by the pulsar velocity rather than that of the scattering medium. This would seem to rule out enhanced ISS from stellar winds themselves which, by analogy with IPS and the solar wind, would yield $V_{ISS} \sim 10^2$–10^3 km s^{-1}.

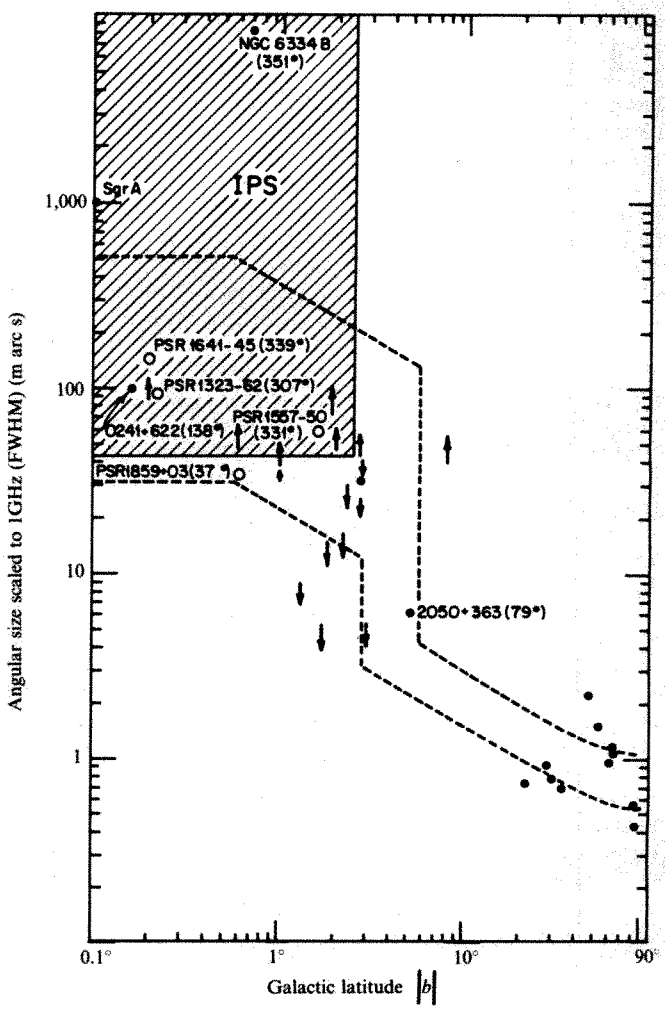

Fig. 1 Scattering diameter at 1 GHz versus galactic latitude for the inner galaxy. ●, VLBI measurements of extragalactic sources[1,26,27] and arrows represent lower and upper limits. The point for NGC6334B is an extragalactic source viewed through the H II complex NGC6334 (ref. 28). ○, Implied angles derived from pulsar scintillation measurements and the effective scattering angle for a source of plane waves at the distance of the pulsar (5–10 kpc). The shaded region summarizes the IPS observations of sources in the direction of the galactic centre[2] and the dashed lines are predicted angles from a survey of pulsar ISS[3].

Pulsar ISS measurements for 76 objects suggest a two-component model for C_n^2: component A with scale height $H_A \geq 0.5$ kpc, $C_n^2 \sim 10^{-3.5}$, and volume filling factor ~1; component B wherein C_n^2 is large in clump-like regions of size $R_{clump} \sim$ 1–10 pc with very small filling factor $\sim 10^{-4}$–10^{-3}, and small scale height, $H_B \sim 50$–100 pc (ref. 3). The pathlength-averaged C_n^2, $\langle C_n^2 \rangle$, increases systematically with decreasing galactocentric radius, suggestive of component B clumps being more common at galactocentric radii smaller than that of the Sun. However, the increase may also reflect an increasing probability for encountering clumps with increasingly larger internal C_n^2. The anticentre directions yield $\langle C_n^2 \rangle$ that are typically smaller than those within the solar circle for the same distance, so that there seems to be a real galactocentric radial dependence. The mean free path for encountering clumps is $L_{mfp} \sim 2$–10 kpc so lines of sight with $|b| \geq 10°$ sample only the 'A' component.

The pulsar results are in good agreement with both recent VLBI and IPS measurements. A recent survey[1] of low-latitude ($|b| < 5°$) compact extragalactic radio sources at 408 MHz shows that 8 out of 18 sources towards the inner Galaxy ($10° \leq l < 80°$)

are sufficiently scattered to yield no fringes implying, typically, $\theta \geq 0.2$–0.3 arc s. By comparison, all 11 sources within $197° < l < 234°$ had $\theta < 0.2$ arc s and only one showed no fringes, probably because it lies behind an H II region. The VLBI results are consistent with a 50% probability for heavy scattering of extragalactic sources in directions $10° \leq l \leq 80°$ and $|b| \leq 1°$. A search for sources that display IPS[2] at 327 MHz in the regions $-10° < l < 30°$ and $180° < l < 210°$ with $|b| < 12°$ show a marked lack of scintillating sources towards the inner Galaxy. Only two out of an expected eight such sources were detected above a flux density of 0.2 Jy for $|b| < 2.5°$, suggesting that the scattering disk due to interstellar scattering ≥ 0.5 arc s, typically.

We combine all data for the inner galaxy in Fig. 1, which shows the equivalent scattering angle (FWHM) at 1 GHz after scaling all measurements according to $\lambda^{2.2}$. VLBI measurements, upper limits, and lower limits are shown as dots or arrows, the IPS results are summarized as a shaded region which designates $\theta > 43$ m arc s for $|b| < 2.5°$, and the pulsar measurements are displayed as predictions for the scattering angle derived from the two-component model. We also show the implied scattering angles for four highly scattered pulsars. Two prediction curves are shown which bracket the expected range of angles. For $|b| \geq 3°$–$6°$, scattering angles are determined by the 'A' medium for nearly all lines-of-sight and are deterministic. For smaller latitudes the scattering angle is a random variable (associated with the probability of intersecting a component B clump) and may fall outside the predicted range, as some of the upper limits apparently do. Break points in the prediction curves occur at angles $\sim H_B/L_{max}$ and $H_A/L_{max} \sim H_B/L_{mfp}$ where L_{max} is the maximum possible pathlength, taken to be 10 kpc. Apart from the break points and the constant parts of the curves for $|b| \leq 0.7°$, the scattering angle varies as $\sim |\sin b|^{-3/5}$ but with different proportionality constants for different ranges of b. We note that our results for $|b| \geq 10°$ agree with previous results based solely on IPS measurements[10,11].

The predicted scattering angle can be considered the apparent diameter of a scattered point source only as long as the condition of strong scattering holds[8]. Roughly, this is true if $q_{eff} \geq q_{Fresnel} = 2\pi/\sqrt{\lambda L}$ or $\theta_{ISS} \geq \sqrt{\lambda/L}$. At smaller λ, the scattered source brightness distribution takes on a core–halo form (for intrinsic source size $\ll$ scattering disk size). At $b = 90°$, $\theta_{ISS} \sim 1$ m arc s at 1 GHz implies that strong scattering occurs for $\lambda \geq \lambda_c \sim 4$ cm. At directions towards the inner Galaxy with $|b| \leq 1°$, $\lambda_c \sim 0.12$ cm for $\theta_{ISS} \sim 100$ m arc s and an effective screen distance of 5 kpc. The compact source Sgr A at the galactic centre with $\theta_{ISS} \sim 1$ arc s at 1 GHz (ref. 12) yields $\lambda_c \sim 0.3$ mm if the apparent source size at decimetric wavelengths is indeed due to scattering. Although free–free absorption[13] from gas with a density $\propto r^{-1}$ can also produce a wavelength dependence $\theta \propto \lambda^2$ and the angular size is an order of magnitude larger than the most scattered pulsar (PSR1641 − 45), the necessary amount of scattering (from the general galactic turbulence as opposed to turbulence local to the source) is not an unrealistic extrapolation of the pulsar results. This follows because Sgr A is further than the most scattered pulsar and the line-of-sight passes through much more ionized material. The pulsar results themselves indicate that θ_{ISS} increases much more rapidly than the $L^{3/5}$ variation that would be expected for a medium with a uniform level of turbulence. We also note that scattering may produce asymmetric images such as has been reported for Sgr A[14]. Turbulence in an anisotropic medium, that is, one with a preferred direction associated with a velocity flow, magnetic field or gradient in the level of turbulence, has an anisotropic wavenumber spectrum which will yield an asymmetric scattering disk. As yet there is no evidence for such an asymmetry from observations of astronomical sources. IPS measurements at 74 MHz (ref. 15) show asymmetric diffraction patterns which are thought to derive from the intrinsic source structure of extragalactic sources because the Crab pulsar, after angular broadening due to ISS, shows no asymmetries in its IPS diffraction. The possibility still remains, however, that sources showing large amounts of scattering will be broadened asymmetrically.

The available evidence implies that scattering occurs along every line-of-sight, albeit by vastly different amounts. Turbulence extends to at least 0.5 kpc in a diffuse component but has large amplitudes in clumps whose distribution resembles a population I class of objects. Pulsars that are known to have intervening H II regions (PSR0611 + 22) or supernova remnants (Crab and Vela) all show enhanced scattering. However, there is no knowledge of the relative importance of a large mean electron density and the energization required to drive the turbulence. What analysis exists implies that considerable energy is required to maintain the density fluctuations[16].

Because of its ubiquity, ISS has important consequences concerning measurements of intrinsic source sizes, ψ. In the conditions $\theta_{ISS} \geq \psi \geq \zeta\theta_c$ where $\zeta \geq 1$ is a dimensionless numerical factor and $\theta_c \sim \lambda/2\pi L\theta_{ISS}$ is a critical angular size, the brightness distribution is irretrievably broadened into a distribution of width θ_{ISS}[17,18]. Only for $\psi \leq \theta_c$ is the radiation field coherent over the scattering disk, a requirement for observing fully modulated interstellar scintillations and for determining ψ from interferometric observations, provided the bandwidth and integration time are less than those characterizing the ISS (for example, Δf_{ISS} and Δt_{ISS} defined above)[17,18]. ISS observations can probe intrinsic sizes with $\zeta = \psi/\theta_c \leq 10^3$ by measuring intensity variations down to a modulation index $m_{ISS} \sim \zeta^{-1} \sim 0.1\%$ (smaller indices are probably impossible to measure because of instrumental effects[19–23] and therefore $\psi \gg \theta_c$ for these sources). (Recent work[24] has suggested that intensity variations of extragalactic sources may be caused by refraction from galactic electron density turbulence. This possibility is peripheral to the issues we discuss here.) Although new classes of extragalactic objects may be discovered which satisfy $\psi \leq \theta_c$, at present it seems that $\psi \gg \theta_c$ for extragalactic sources and therefore any interferometer observation will measure an angular size θ_{ISS} if $\psi < \theta_{ISS}$ and $\lambda > \lambda_c \sim 4$ cm (observing perpendicular to the galactic plane). Therefore, interferometer observations with baselines $\sim 10 R_{Earth} f_{GHz}^{1.2}$ will tend to be dominated by ISS, and baselines twice this size will totally resolve the scattering disk (for $f \leq 7$ GHz or $\lambda > \lambda_c \sim 4$ cm). Taking $\theta_{ISS} = 0.5$–2.0 m arc s at 1 GHz, we find that the maximum observable brightness temperature for high-latitude sources is

$$T_{b\,max} \approx 10^{12.1 \pm 0.6} S_{Jy} f_{GHz}^{2.4}\ \text{K}, f \leq 7\ \text{GHz} \qquad (3)$$

Therefore, intrinsic source structure having a brightness temperature close to or in excess of the inverse Compton limit ($\sim 10^{12}$ K) will be difficult, if not impossible, to resolve at frequencies < 1 GHz. We point out, however, that the detection of diffraction-produced intensity variations at sub-GHz frequencies would necessarily imply $T_b > 10^{12}$ K (refs 19–21).

The only known class of sources for which these limitations can be overcome are pulsars, which show interstellar scintillations and whose emission regions satisfy $\psi < \theta_c$ (ref. 25). VLBI observations with bandwidth and integration time smaller than Δf_{ISS} and Δt_{ISS}, respectively, will yield fringes on baselines $\leq \lambda/\psi$ whose phase and amplitude vary randomly on a time scale Δt_{ISS}. Consequently, fringes should be detectable out to at least 1 AU for a typical pulsar at 1 kpc distance and probably on much longer baselines because emission regions are evidently much smaller than the light cylinder radius[25].

We thank R. V. E. Lovelace for useful discussions. This research was supported by the National Astronomy and Ionosphere Center which is operated by Cornell University under contract to the NSF. It was also supported by the Alfred P. Sloan Foundation (J.M.C.) and NSF grant AST-8311844 to Cornell University.

Hercules X-1—a 1,000 GeV γ-ray pulsar

J. C. Dowthwaite, A. B. Harrison, I. W. Kirkman, H. J. Macrae, K. J. Orford, K. E. Turver & M. Walmsley

Department of Physics, University of Durham, Durham DH1 3LE, UK

An X-ray pulsar has been detected for the first time as a very high-energy (VHE) γ-ray pulsar. X-ray emission from Hercules X-1 is multiply periodic with a pulsar period of 1.24 s, a binary orbital period of 1.7 day and a 35-day amplitude modulation of unknown origin characterized by a sharp turn-on followed by a slow decline over 11 days. During a drift-scan we have detected a significant 3-min outburst of VHE γ rays, which had a 1.24-s periodicity. This outburst occurred 35 days before an observed X-ray turn-on. The γ-ray luminosity during the outburst was of the same order as the X-ray luminosity. Together with the coincidence in time, this suggests a connection between the mechanisms giving rise to the γ-ray outburst and the X-ray turn-on. Subsequent monitoring of the source during a period when the X-ray flux was decreasing yielded some evidence of much weaker pulsed γ-ray activity at the pulsar period. We note a possible similarity between this system and Cygnus X-3.

The discovery of Her X-1 as a pulsing (1.24-s period), eclipsing binary X-ray source was made by the UHURU group[1]. The optical counterpart was identified as Hz Herculis[2] following an improved positional determination for the X-ray source and the detection of a related 1.7-day orbital period.

Studies[3,4] of this first binary X-ray source to be detected reveal that the emission from the system is complex but involves variable emission of X-ray and optical photons with modulations, differing with wavelength, on time scales of 1.24 s, 1.7 and 35 days, the first two being attributed to the pulsar and binary orbit respectively. The origin of the 35-day modulation is less clear. It has been related to the 1.7-day orbital period[5], although many theories have been based on the precession of the rotation axis or the obscuration of our view by a periodically moving disk. The pulsar period has been observed to spin up at a rate, averaged over 11 yr, of about 10^{-13} s s^{-1}. Recent measurements of the X-ray pulse period have been made by the Hackucho and Tenma satellites[6]. In two observations in June 1982 and May 1983, the X-ray data show periods of 1.2377870 s and 1.23778873 s respectively, agreeing broadly with the long-term trend for the pulsar to spin up, but with large and opposite signs of period derivative: $(+7.4 \pm 5.9) \times 10^{-13}$ s s^{-1} and $(-3.6 \pm 1.3) \times 10^{-13}$ s s^{-1} respectively. Optical and IR measurements[7] made in July 1982, a date between the X-ray observations, suggested that the period could be much longer, perhaps as long as that noted in 1972. There is thus recent evidence for a large excursion of the pulsar period from the long-term trend, which is consistent with the indications for the behaviour in 1982–83 suggested by the signs of the X-ray period derivatives. Data on the pulsar period for the past 11 yr are summarized in Fig. 1.

Observations of Her X-1 were made on 17 April 1983 using the array of four telescopes of the Dugway VHE γ-ray facility[8,9]. The telescopes have an energy threshold of ~1,000 GeV, an aperture of ~2° FWHM and a sensitivity (for a 3σ detection of pulsed emission lasting for 10 min) of $\sim 3 \times 10^{-10}$ cm^{-2} s^{-1}. The initial observation comprised four drift scans, each lasting 40 min. The time of arrival of each recorded light flash was corrected to the Solar System barycentre. Assuming that the source of any γ rays is located at the same part of the system as the X-ray source, the times were corrected to the binary focus using the X-ray orbital ephemeris[10].

Emission of VHE γ rays from Her X-1 was noted in the April observation as a marked outburst in the count rates of our telescopes during one of the four drift scans, which were taken in ideal sky and stable experimental conditions. The excess for the total time that Her X-1 was in the field of view of the telescope was $14 \pm 7\%$. The data indicated that the activity lasted for ~3 min, during which an enhancement of $33 \pm 10\%$ in the gross count rate occurred (see Fig. 2*a*). The events during this outburst were periodic with the characteristic X-ray pulsar period (Fig. 2*b*). Because the expected light curve is unknown at these energies, the general Rayleigh test[8] for the strength of the first harmonic of a periodicity was used. The inherent sampling resolution of the periodicity is ~3 ms, rendering redundant the reduction of the orbit to the focus and preventing the measurement of an accurate period. The probability of this periodicity arising by chance is 4×10^{-4}, with an estimated first harmonic periodic content of 39%. The excess periodic γ-ray counts detected in the drift scan are therefore practically 100% pulsed. The profile of the pulsed component through the scan is depicted in Fig. 2*c* as the per cent pulsed in 3-min sliding sections. (The apparent narrowness of the peak in Fig. 2*c* compared with that in Fig. 2*a* is due to the nonlinear relation between chance probability and per cent pulsed signal.)

The increase in count rate and periodicity were shown both by those events triggering a single telescope, and independently by those events in which two telescopes detected the Cerenkov light pool from the same (perhaps higher energy) primary. The excess occurred ~5 min before the object was in the centre of the field of view of the telescope. Inter-detector fast timing indicates that the pulsed events in the excess arrive from a direction ~1° below the centre of the field of view coinciding with the position of Her X-1. There is therefore, in one of four drift-scans, a $>3\sigma$ count rate excess for 3 min from Her X-1, which is periodic at a $>3\sigma$ level at the X-ray periodic. Allowing for the degrees of freedom, the overall statistical significance of this single observation is 7×10^{-5}. The light curve for those events in the 3 min of activity is shown in Fig. 3 and has the

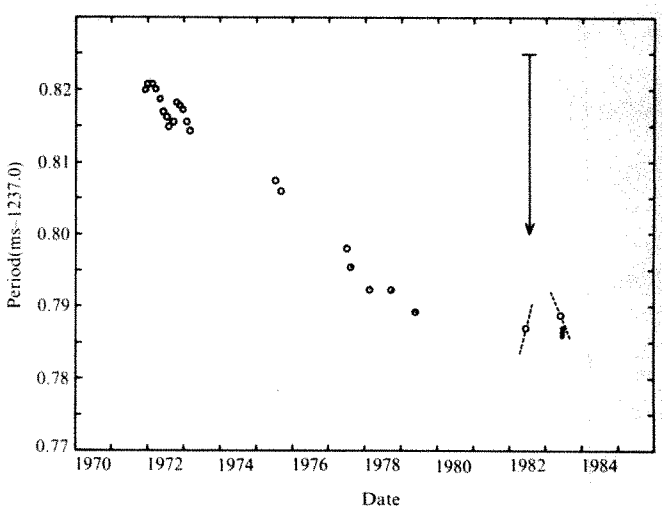

Fig. 1 The period of the Her X-1 pulsar. ▮, Present value derived from the July observation; earlier values are from refs 6, 7. Dashed lines indicate the measured period derivative in X-ray observations.

characteristic broad single peak seen in X rays[11] (with a width about 30%). The peak γ-ray flux during the burst of activity is 1.2×10^{-9} cm^{-2} s^{-1}. The outburst occurred at phase 0.76 in the 1.7-day period and 35 days before a detected turn-on in X rays[6].

Following the 17 April 1983 outburst, Her X-1 was tracked during 3–13 July 1983 and 7–11 October 1983. No further large count-rate excess in a 3-min interval similar to the April event was seen. The July data show an overall periodicity at the 2σ level. Although contributing little to the statistical significance of the detection, these data taken over a prolonged interval allow a test of the accurate Tenma period. The 2σ effect was noted within the sampling range of the extrapolated period from the 1983 May Tenma X-ray measurement (1.2377873 s) and the detected period is indicated on Fig. 1. The time-averaged flux of γ rays is $0.84\pm0.4\%$ of the background cosmic ray flux, corresponding to a flux of $(3\pm1.5)\times10^{-11}$ cm^{-2} s^{-1} for energy >1,000 GeV.

We conclude that Her X-1 is emitting pulsed VHE γ rays sporadically with chance probability of 7×10^{-5} and a peak flux of 1.2×10^{-9} cm^{-2} s^{-1} above an energy of 1,000 GeV at a time in April 1983 when, according to the Tenma satellite data on 22 May 1983, the X-ray turn-on in the 35-day cycle may reliably be expected. The short outburst occurred at phase 0.76 in the 1.7-day orbit when the pulsar in the binary system was moving almost directly away from the Earth. X-ray turn-on has been observed to occur around phase 0.2 or 0.7 in the 1.7-day cycle every 35 days. The optical emission is also strongest at these same two phases[12]. The shortest known time for turn-on is <700 s, being the interval between successive X-ray observations. It is thus possible that the X-ray turn-on is accompanied by the emission of a burst of VHE γ rays lasting ~3 min. If this were the case, an X-ray turn-on took place on 17 April 1983 08.44 UT.

The July 1983 data indicate at the 2σ level that a time-averaged flux of 3×10^{-11} cm^2 s^{-1} exists at the precise pulsar period according to a contemporaneous X-ray measurement (1.2377873 s), if we assume that the VHE γ rays originate with the X rays and make the appropriate allowances for the 1.7-day orbit. A conservative estimate of the probability of chance occurrence of the April event and the overall July emission is 5×10^{-5}.

The VHE γ-ray data were taken when unusual behaviour of the temporal features of the X-ray and optical components was reported [5,7] and when the X-ray flux was decreasing. The time-averaged VHE γ-ray luminosity is 2×10^{35} erg s^{-1} (assuming a differential spectral slope of −3 and distance 5 kpc), which is ~0.5% of the X-ray luminosity including soft X rays.

We know of no previous attempt to detect VHE γ rays from this object. Flux limits[13] on other X-ray sources suggest typical limits of 10^{-10} cm^{-2} s^{-1} at an energy of ~1,000 GeV. The only other (and much more distant) X-ray binary source to be detected in VHE γ rays is Cygnus X-3. The emission from Cyg X-3 peaks at 10^{-9} cm^{-2} s^{-1} during short intervals of the 4.8-h binary period. The duration of the intervals of emission detected during drift scans vary from 15–30 min (ref. 14) to 1 h (ref. 15) (although these durations may be maximum values as they are similar to the duration of the drift scans) and they occur about 0.3 of a 4.8-h period before the X-ray minimum. Continuous observation of the object suggest that the emission may be as short as 3 min (ref. 9). In addition there have been indications that the strength of this 4.8-h periodic emission in both X rays and VHE γ rays

is itself modulated with a 34.1-day period. There is thus a resemblance between the VHE γ-ray properties of Cyg X-3 and Her X-1, although a pulsar period remains to be detected for Cyg X-3.

This work was funded by the SERC and was carried out at Dugway Proving Ground, Utah. We thank the commander and staff there for continued support of our experimental programme.

Extraterrestrial platinum group nuggets in deep-sea sediments

D. E. Brownlee, B. A. Bates & M. M. Wheelock

Department of Astronomy, University of Washington, Seattle, Washington 98195, USA

Iron cosmic spheres, composed of iron oxides surrounding a FeNi metal core, were discovered more than a century ago during the voyage of the HMS *Challenger*[1]. That the spheres originated by atmospheric melting of meteoritic metal is supported by a variety of evidence, including elemental composition[2], the presence of the metastable oxide wustite[3], similarity to analogues produced in the laboratory[4] and content of ^{53}Mn produced by exposure to cosmic rays[5]. We report here a previously unrecognized property of the spheres. The most common spheres larger than 300 μm do not, in act, contain FeNi metal cores, but instead contain a micrometre-sized nugget composed almost entirely of platinum group elements. These elements appear to have been concentrated by the oxidation of molten meteoritic metal during atmospheric entry. This process is critically dependent on the relative abundance of oxygen in the atmosphere, and the first appearance of the nuggets in the geological record may provide a marker indicating when the oxygen abundance attained half of its present level.

The spheres used in this study were collected with a magnetic collection sled (the Cosmic Muck Rake), towed across two locations on the ocean floor 1,000 km east of Hawaii[6]. The platinum group nuggets (PGN) were first identified as 5–10-μm diameter spheres in sectioned iron spheres (Fig. 1). A survey of 110 such polished sections, 300–500 μm in diameter, revealed four PGNs. We then mounted 11 300-μm iron spheres and sequentially polished completely through them, inspecting them at 1–2 μm depth intervals. Solitary PGNs were identified in seven of the spheres; additional nuggets may have been plucked out during polishing. None of the PGN-bearing spheres contained FeNi metal cores. From statistical analysis of these results we conclude that half or more of the spheres >300 μm contain a single PGN, that less than half contain the previously described large FeNi metal cores and a smaller fraction contain no metal at all.

The analyses of 10 nuggets shown in Table 1 and Fig. 2 were obtained by energy dispersive X-ray analysis in an analytical scanning electron microscope (SEM). This approach was chosen in preference to the electron microprobe so that the beam could be precisely located on the nuggets. Pure element standards were used and ZAF corrections were made to determine absolute concentrations. The *L* lines were used for elements heavier than Ni and peak integrals were determined by the 'super ML' multiple least squares fitting procedure[7]. The accuracy of this method for the moderately overlapping lines of Ru, Rh and Pd was confirmed by tests on synthetic spectra that closely matched those of the samples.

The analyses show that the nuggets are exotic alloys of group VIII refractory siderophile elements. More than 70% of the mass of a typical nugget is composed of Os, Ir, Pt and Ru. As seen in Fig. 2, five of the nuggets have unfractionated chondritic compositions for the platinum group elements. The mass of these elements in a nugget is consistent with formation by efficient concentration from a sphere of meteoritic metal similar in size to the host oxide sphere. Four of the nuggets have systematic depletions that correlate well with volatility; especially conspicuous are large depletions of Ni and Pd. One nugget is enriched in the more volatile platinum group elements.

A conceivable origin for the nuggets is that they are preserved relics from parent meteoroids and resemble platinum group nuggets found in carbonaceous chondrites[8,9]. The nuggets reported here, however, are much more abundant and are generally larger than those of similar composition found in meteorites. The strongest argument against this source is that PGNs are never found in stony cosmic spheres. In our examination of polished sections of 1,000 stony (chondritic) cosmic spheres in the 300 μm to 1 mm size range, no PGN was observed.

The most likely origin of the PGNs is that they are the natural product of the heating and oxidation of small meteoritic metal particles during hypervelocity entry into the atmosphere. As the metal melts and begins to oxidize, elements more noble than iron remain in a rapidly shrinking metal bead surrounded by a growing shell of immiscible molten iron oxide (Fig. 3). If oxidation is not extreme, the sphere retains a relatively large Ni-enriched metal core. Nickel enrichment by this process is observed in deep-sea spheres[10] and also in spheres associated with terrestrial impact craters[11,12]. With more complete oxidation, most of the iron and nickel leaves the metal core and the result is a PGN. None of the platinum group elements is oxidized because of the low partial pressure of oxygen at the altitudes (70–90 km)[13] where the spheres are molten. Oxidation of Os can occur at this pressure ($< 10^{-5}$ atm for O_2) only if the temperature is below 600 °C (ref. 14); by the time the sphere is this cool, the nugget has been encased in solid iron oxide.

If heating is not severe (for example, due to low entry angle or velocity), the comparatively volatile elements like Rh, Ni and Pd are retained and a chondritic abundance pattern like the flat curves in Fig. 2 can be preserved. Extreme cases of heating result in vaporization of Ru, Pt, Rh, Pd and Ni and the product is a highly fractionated Os, Ir rich nugget, as seen in the lower

Fig. 1 Scanning electron micrograph of an 8-μm platinum group nugget in a polished section of an iron type cosmic deep-sea sphere. The host sphere is composed of magnetite and wustite.

Table 1 Analyses of 10 platinum group nuggets

curves of Fig. 2. Temperatures above 2,400 °C are required to produce significant Ru vaporization[15,16] during the 5 s of peak heating that typical small particles experience near altitudes of 80 km (ref. 13). Significant heating above this temperature would result in vaporization of the oxide shell and the final product would be a bare nugget composed mostly of Os and Ir. Although these bare nuggets have not been observed, they may be more common than those embedded in oxide shells. The Pt/Ru/Rh-rich nugget (the highest curve in Fig. 2) cannot be produced by volatile loss from a source of chondritic composition. Unlike the other nuggets, this one must have originated from a source that has a Pt/Ir ratio higher than chondritic, possibly a III A,B iron meteorite[17]. One remarkable aspect of PGN formation in iron spheres is that the Pt group metals are efficiently concentrated by factors of $>10^5$ above chondritic on a time scale of a few seconds.

We conclude that typical half-millimetre particles of meteoritic metal are severely heated and oxidized during entry into the atmosphere and that these processes concentrate the refractory platinum metals into a small bead $\sim 10\ \mu m$ in size. As described elsewhere[18], there is evidence that most of the iron cosmic spheres are actually not melted iron meteoroids but droplets produced by reduction in carbon-rich chondritic particles undergoing pulse heating at the top of the atmosphere. If this is the case, then a considerable fraction of the Os and Ir currently being accreted by the Earth could be in the form of PGNs. If this process occurs during major inputs of extraterrestrial material into the atmosphere, for example, at the end of the Cretaceous[19], PGNs would form in enormous numbers. The nuggets should be quite stable to alteration and might survive as unique physical markers, while other debris weathers beyond recognition.

The formation of PGNs in iron cosmic spheres requires essentially total oxidation, a process that is only barely possible with the present abundance of oxygen in the atmosphere. Assuming that an impacting air molecule transfers all of its momentum to the decelerating meteoroid, then the particle will decelerate to 13% of its entry velocity after it has encountered an air column whose mass is twice the particle mass. Below this velocity the particle will not remain molten and PGN formation cannot occur. This simple momentum transfer calculation shows that during the time that a small iron meteoroid is strongly heated by atmospheric friction, it collides with a total number of oxygen atoms that is less than twice the number of iron atoms in the particle. Accordingly, we predict that iron cosmic spheres that formed before the abundance of oxygen in the atmosphere reached half its present level could not be totally oxidized during entry and should not contain PGNs. The study of PGNs in iron cosmic spheres recovered from dated stratigraphical layers may provide a means of determining when in the Earth's history the oxygen abundance rose to half its present level.

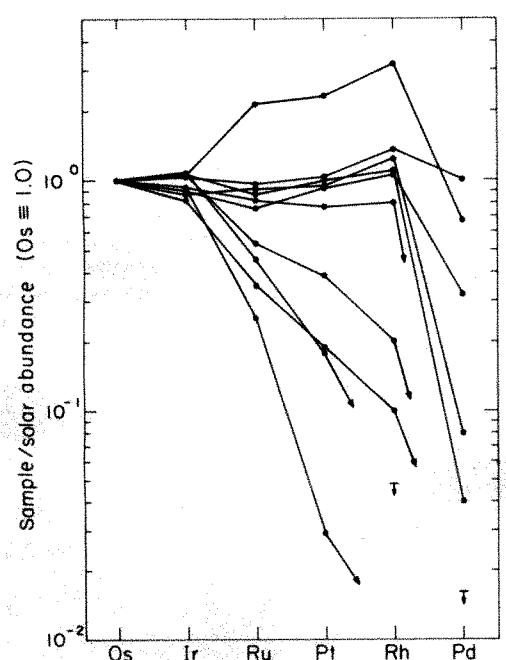

Fig. 2 Abundances of the 10 platinum group nuggets in Table 1 are normalized to the solar composition data of Anders and Ebihara[20]. The data were not directly normalized to CI chondrites because Rh abundances have not been published for carbonaceous chondrites. The elements are plotted in order of increasing volatility from left to right. Temperatures required to produce vapour pressure of 1 torr range from 3,500 °C for Os to 1,900 °C for Pd. This vapour pressure produces vaporization at a rate of the order of 5×10^{-3} cm s^{-1} for a pure element[19,20]. Arrows descending to the right indicate abundances below the indicated detection limits for Rh and Pd.

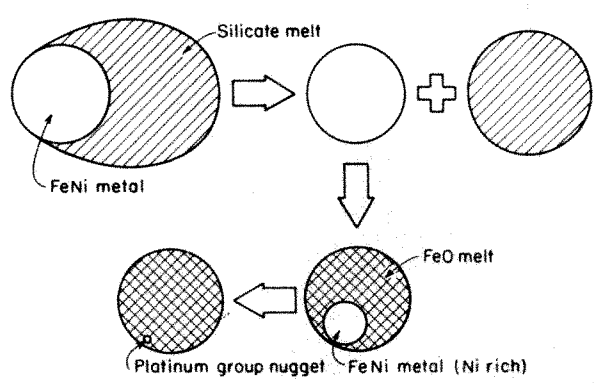

Fig. 3 The most common sequence of events that produces iron cosmic spheres containing platinum nuggets. An interplanetary dust particle melts during atmospheric entry and forms the composite spheroid of molten silicate and metal shown in the upper left. Due to their large density differences, the metal and silicate fractions separate by inertial forces forming a metal sphere and a silicate sphere[18]. The metal sphere develops a rapidly growing oxide shell and siderophile elements more 'noble' than iron concentrate into the shrinking metal core. When oxidation is nearly complete, most of the iron and nickel leave the core, resulting in a small nugget of nearly pure platinum group elements. Continued strong heating may vaporize the oxide shell, leaving only the nugget.

Evidence from core-reflected shear waves for anisotropy in the Earth's mantle

Yoshio Fukao

Department of Earth Sciences, Nagoya University, Chikusa, Nagoya 464, Japan

Seismologists have begun to recognize that the upper mantle at depth is anisotropic and that seismological data are not fully explicable if anisotropy is ignored[1–5]. On entering an anisotropic zone a plane shear wave splits into two orthogonally polarized phases[6]; an effect observed by several researchers[7], notably by Ando *et al.*[5,8,9]. The near vertical ScS wave, an S wave reflected once at the core–mantle boundary, is one of the most suitable phases to study the phenomenon of shear wave birefringence because it is isolated from other phases and because its particle motion is nearly horizontal and thus free from S to P conversion. The split ScS shear waves travel with different velocities in the anisotropic zone and consequently there is a time delay between their arrival at stations. My aim was to determine this time delay and the azimuth of polarization using the ScS records of two horizontal components from the Japanese islands for a deep shock beneath the Sea of Okhotsk. From the total of 41 stations 34 show a polarization of the maximum velocity phase in the NNW–SSE direction with an average time advance of ~0.8s from the minimum velocity phase. The relevant anisotropic zone seems to be deep-seated.

The particle motion of the ScS wave before it enters an anisotropic zone must satisfy two conditions for the splitting phenomenon to be well observed. First, the particle motion should not be closely parallel to one of the principal axes of anisotropy as little shear wave splitting occurs in such cases. Second, from the focal mechanism point of view, the particle motion must have a large amplitude. The earthquake studied is a rare event that meets these two conditions at almost all the Japanese stations (see Table 1).

The hypocentral parameters of this earthquake are given by ISC as follows: date, 29 January 1971; origin time, 21 h 58 min 03.2 s; epicentre, 51.69° N, 150.97° E; depth, 535 km (pP–P); magnitude, $m_b = 6.0$. We used the data from the three-components seismographs with a natural pendulum period of ~5 s (courtesy of S. Mori of JMA) at 41 stations of the Japan Meteorological Agency (JMA). The epicentre and the station distribution are shown in Fig. 1. The ScS rays are nearly vertical incident to each station because of their closeness to the epicentre. The original paper speed of the JMA seismograms was either 3 cm s^{-1} (smoked paper) or 6 cm s^{-1} (ink writing). All the ScS records of horizontal components were enlarged to an equivalent paper speed of 12 cm s^{-1} and digitized every 0.2 s with an interval of 20 s. The digitized records were then corrected for the armlength of the pen recorder. Figure 2 shows several examples of the resultant horizontal traces; three methods were used to analyse them.

(1) Two horizontal records were synthesized into a particle motion diagram. In the absence of anisotropy the particle orbit was expected to be linear. After passage through an anisotropic zone, however, the particle motion would start with a movement along the polarization azimuth of the maximum-velocity phase and end with a movement along the azimuth of the minimum-velocity phase. The locus in between was expected to be approximately elliptical for a long-lasting signal. As seen in Fig. 2, the initial swing of the observed particle motion was generally directed towards the south-southeast. This swing was then followed by a counterclockwise elliptical rotation. It was difficult to identify the last swing of the ScS motion because of the coda waves. In some cases, however, a last swing towards the east-northeast was seen for example, at URA, ISN, KYO. The particle motion diagrams thus offer a diagnostic demonstration for the existence of anisotropy in the Earth with its maximum velocity polarized in the NNW–SSE direction.

(2) Two horizontal seismograms were rotated in a clockwise direction. An appropriate rotation would resolve the ScS wave

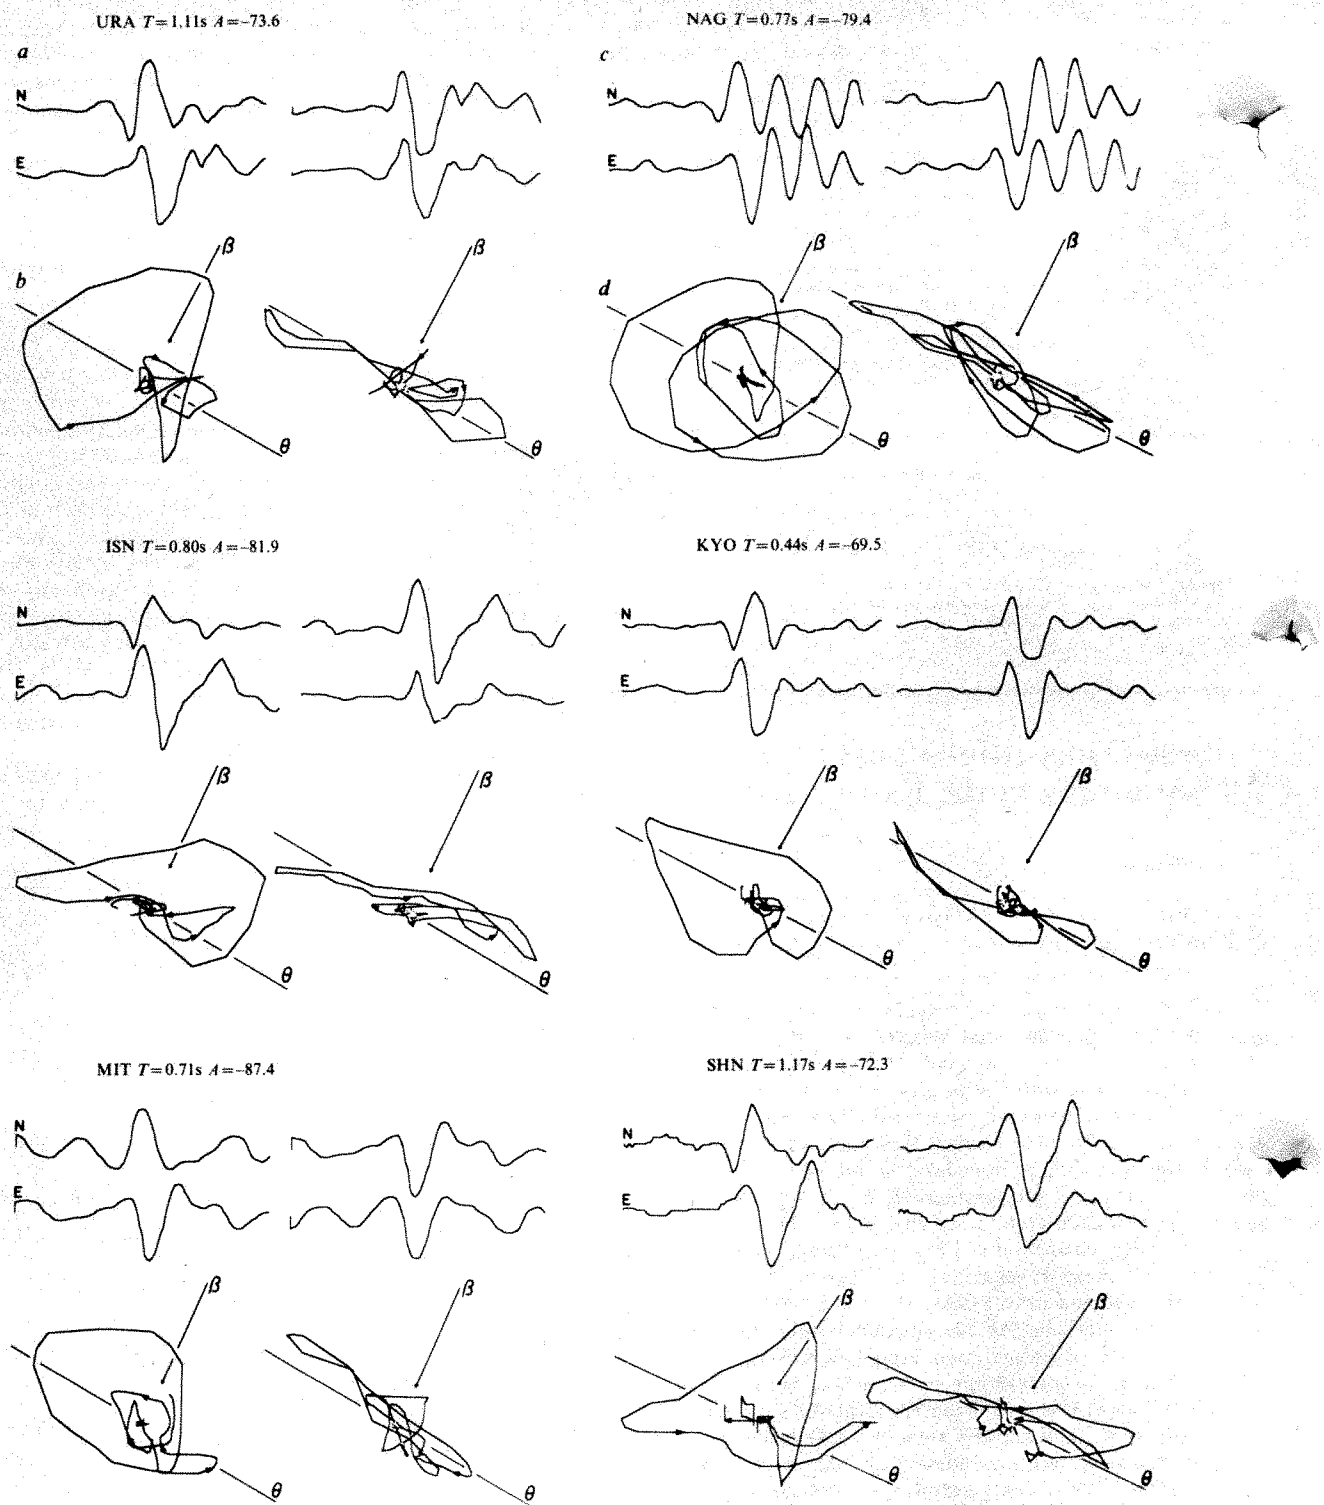

Fig. 2 ScS seismograms at six selected stations (see Fig. 1 for locations). The sampling time is 20 s from the beginning to the end of each trace. *a*, Original north–south and east–west seismograms. *b*, Original particle motion diagrams. β Indicates the incident azimuth of ScS wave and θ the direction of ScS motion expected from the focal mechanism[10]. The expected ScS motion is nearly transverse. *c*, Anisotropy-corrected seismograms obtained by a clockwise rotation A and a relative timeshift T. *d*, Anisotropy-corrected particle motion diagram.

into two orthogonally polarized phases whose wave-forms must be similar to each other. To find an appropriate azimuth of rotation a correlation was taken between the two rotated seismograms. Values for the rotation azimuth φ and the time lag τ yield the maximum correlation and were used to give the axes of anisotropy and a time delay between two polarized phases. (3) Two horizontal seismograms were rotated clockwise and then relatively shifted in time. Appropriate rotation and time shift would show a linear orbit in the resultant particle motion diagram. A straight line was fitted to the particle orbit of rotated and time-shifted seismograms. The rotation azimuth φ and the time shift τ that give the best straight-line fit were, in general, consistent with those obtained by the second method, but did not coincide exactly. A set of φ and τ values which were in better agreement with the qualitative result from the first method were adopted as the final solution.

Figure 2 shows several examples of the seismograms rotated by an angle φ and relatively shifted by a time τ, and are thus corrected for anisotropy. Their waveform correlation is much better than that of the original north–south and east–west seis-

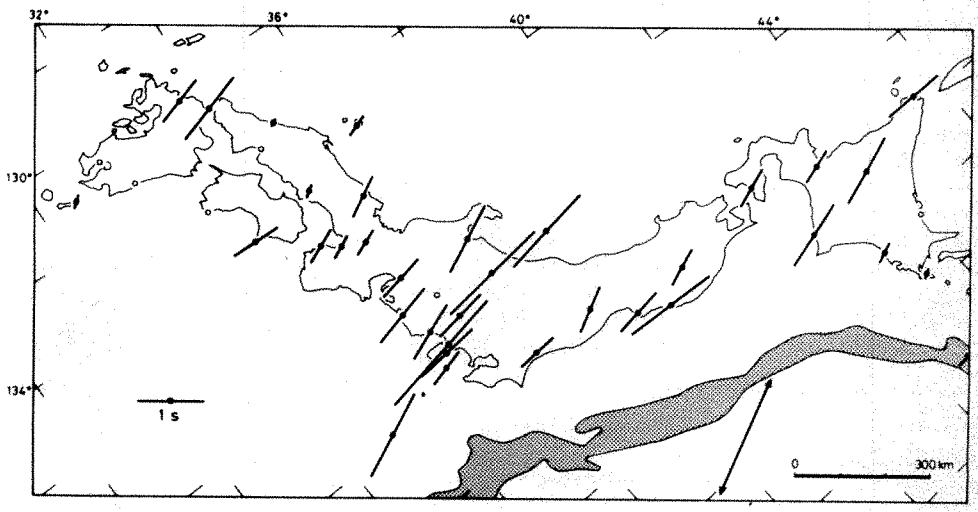

Fig. 3 Polarization azimuth of maximum-velocity phase of ScS wave and time delay between maximum- and minimum-velocity phases. Arrow indicates the azimuth of maximum velocity for horizontal propagation of P waves through the oceanic lithosphere[1].

mograms. Figure 2 also shows the particle motion diagrams corrected for anisotropy. Again the orbital linearity is much better than that of the uncorrected particle motion diagrams. As pointed out by Ando *et al.*[8,9], the linear trend of the corrected particle motion must agree with the direction of the ScS motion predicted by the P wave nodal plane solution. The direction of the ScS motion is calculated for the nodal plane solution given in Table 2 of ref. 10. The direction so calculated is attached to each of the particle motion diagrams corrected for anisotropy; the agreement is very good. The average of the azimuthal differences between the observed trend and the predicted one is $4 \pm 12°$ (35 stations, see Table 1).

The result of the analysis is summarized in Table 1 and is shown in Fig. 3. The uniformity in polarization azimuth is remarkable. Out of 41 stations, 34 show a polarization of the maximum-velocity phase in the NNW–SSE direction. These stations are distributed over all the Japanese islands (Fig. 3). Only NAH, the most distant station from the epicentre, shows a polarization in the east–west direction. If this station is excluded, an average polarization azimuth of (N17° W–S17° E) ± 10° is obtained for the maximum-velocity phase with an average time advance of 0.8 ± 0.4 s from the minimum-velocity phase. A time difference of 0.8 s corresponds to a velocity difference of 4–5% in an anisotropic zone with a vertical extent of 100 km. The velocity difference would be reduced to a half if both the downgoing and upgoing ScS waves pass this anisotropic zone. For the remaining six stations I could not obtain the result with confidence for the reasons outlined in Table 1.

I conclude that there is an anisotropic zone in the ScS ray paths from the hypocentre to the Japanese islands. It is impossible to locate the site of anisotropy from the present analysis. It would, nevertheless, be rather surprising if the upper mantle above the deep seismic zone were to be so uniformly anisotropic over the whole Japanese islands in a variety of tectonic settings. In fact, Ando *et al.*[8,9] observed that the anisotropic nature above the deep seismic zone in Central Honshu, Japan, varies considerably even on a horizontal scale of 100 km. The observed uniformity in polarization azimuth seems to indicate that the relevant anisotropy is deep-seated. For example, the anisotropy may reside in the descending slab of lithosphere. If this is the case, the ScS waves encounter the anisotropic zone at least once near

the source and in most cases once again beneath Japanese stations (Fig. 1). The oceanic lithosphere seaward of the Kurile–Japan trench is strongly azimuth-dependent for horizontal propagation of P waves, the direction of maximum velocity being N25° W–S25° E[1]. Note that this direction approximately coincides with the polarization azimuth of the maximum-velocity phase of near-vertical ScS wave. If the oceanic lithosphere consists primarily of olivine crystals whose *a*-axes are aligned in the NNW–SSE direction, both the P and S wave observations could be explained (see ref. 9). Of course, this argument is not valid, if the source of shear wave splitting were located below the depth of olivine–spinel transition.

I thank M. Ando for critically reading the manuscript.

Subduction regression and oceanward migration of volcanism, North Island, New Zealand

R. N. Brothers

Department of Geology, University of Auckland, Private Bag, Auckland, New Zealand

In the North Island of New Zealand, calc-alkaline igneous eruptions commenced in the early Miocene and continued into the Holocene in the central Taupo and Egmont areas, but no comprehensive synthesis exists to explain either the volcanic sequence or the regional structural setting. New data, reported here, from K–Ar ages and K_2O–SiO_2 indices for magma source depths indicate an oceanward migration pattern for volcanism, from north-west to south-east towards the Hikurangi Trench. Movement of this volcanic front throughout the Neogene and Quaternary was controlled by subduction zone regression[1] which followed rapid, shallow, non-volcanic Oligocene underplating of the island. In areas of accelerated subduction retreat, tensional tectonism caused widespread foundering of the Mesozoic greywacke basement.

Regional calc-alkaline volcanism in the North Island of New Zealand, of early Miocene–Holocene age, is confined to an area north-west of the main axial range of basement Mesozoic greywackes. Two geographically and petrologically distinct systems of eruptive rocks trend NW–SE parallel to the length of the island (Fig. 1) and contain contrasted calc-alkaline suites: basalts, andesites and rare dacites in the West Belt; and andesites, diorites, dacites, rhyolites and rare basalts in the East Belt[2,3]. The two belts lie on opposite sides of the Stokes Magnetic Anomaly System[4] which may represent the trace of an ancient convergence zone separating older, thicker (Palaeozoic) crust on the west from younger, thinner crust on the east. The NW–SE elongation of the volcanic belts has previously been regarded as an alignment of eruptive centres above a subduction system that flowed under the North Island from NE to SW, forming a Miocene–Pliocene interface between the Pacific and Indian plates[5,6]. Subsequently, this inference has not been supported by the age and orientation of magnetic spreading lineaments in the South Fiji Basin[7] or by the distribution of preliminary K–Ar dates within the volcanic belts[8]. Moreover, Quaternary calc-alkaline eruptive rocks are distributed along a line of volcanism which trends NE–SW from Taupo Volcanic Zone to Egmont

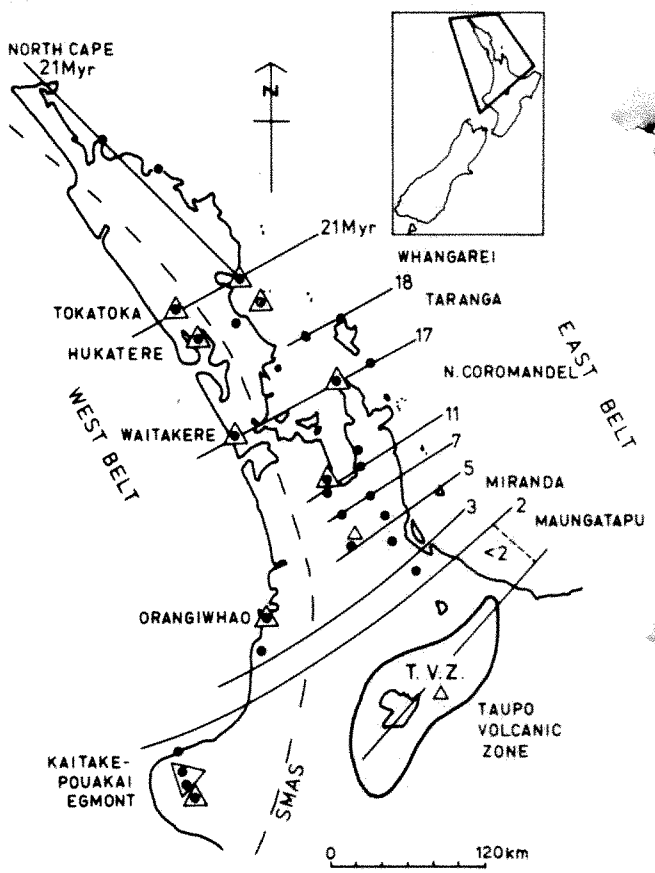

Fig. 1 The northern part of North Island, with the Stokes Magnetic Anomaly System (SMAS) separating the West Belt of calc-alkaline volcanism (Tokatoka to Egmont) from the East Belt (North Cape to Whangarei, and Whangarei to Taupo Volcanic Zone). ●, ○, including the boundary line for Taupo Volcanic Zone (TVZ), provide an indication of the distribution of calc-alkaline volcanic centres in North Island and also give specific locations for K–Ar ages (total of 93 dates) from which the time-lines were determined. △, with place names, are localities for K_2O–SiO_2 estimates of magma source depths shown in Fig. 2.

(Fig. 1) and is almost orthogonal to the East and West Belts, the related modern subduction system, dipping to the north-west, is well defined from seismic data and it originates at the Hikurangi Trench where the Pacific plate descends at an initial shallow angle (~15°) below the edge of the (North Island) Indian plate and then steepens to 50–60° below Taupo–Egmont[6,9].

Additional K–Ar ages for andesites, diorites and dacites within both volcanic belts have provided time-lines (Fig. 1) which represent the oldest dated rocks, and thus the initiation of volcanism, at eruptive centres throughout the northern North Island, and two orientations are apparent.

(1) In the northernmost part of the island, a NW–SE 21-Myr time-line lies along the eastern side from North Cape to Whangarei. Andesites in this zone are unique within the North Island by containing garnet or high-pressure igneous mineralogies, and by having a close association in the field with ophiolite massifs; their origin is believed to belong to a brief magmatic event which accompanied ophiolite obduction at ~23–25 Myr, at the end of Oligocene seafloor spreading in the South Fiji Basin[7,10].

(2) Time-lines with NE–SW orientation record southeastward migration of calc-alkaline volcanism over a distance of 320 km from Whangarei (East Belt)–Tokatoka (West Belt), with oldest ages of 21 Myr, to the Quaternary volcanoes of the Taupo Volcanic Zone (East Belt) and the Egmont group (West Belt). The parallelism of the time-lines and their progressive younging from north-west to south-east are evidence for continued migra-

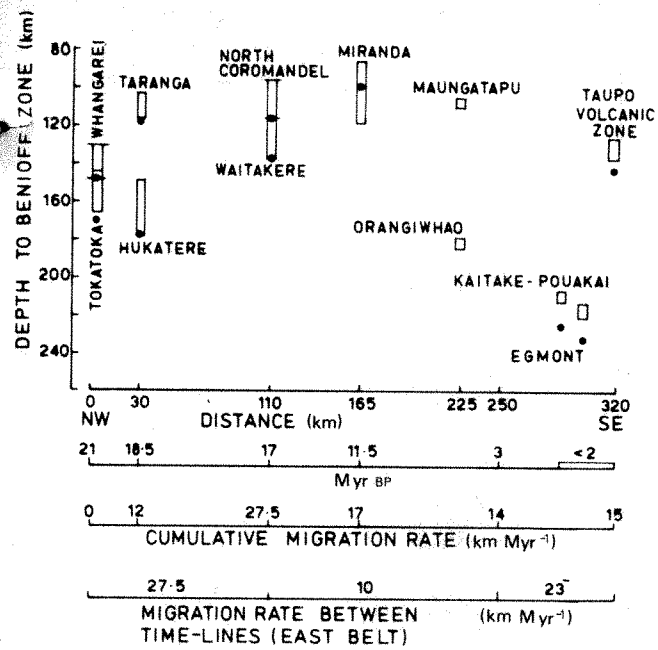

Fig. 2 K_2O–SiO_2 estimates of depth to magma sources, plotted against NW–SE distance from Whangarei–Tokatoka (21 Myr time-line) to Taupo Volcanic Zone–Egmont (<2 Myr) as measured along the East Belt. Rectangles show the total estimated depth range at the centre of the Benioff zone based on the K_{55} and K_{60} method[11]; ●, the maximum estimated depth to the inferred base of the Benioff zone using the $K_{57.5}$ method[12]. The depth shown for Maungatapu is a minimum (using only K_{55} data) and for Orangiwhao is a maximum (using only K_{60} data).

tion of the subduction profile which currently underlies the Taupo–Egmont volcanic centres, with a north-west polarity. Thus, from early Miocene to present day, a mobile volcanic front has accompanied the southeastward retreat of a magma-generating subduction surface (Benioff zone) which developed as a result of oceanward regression of a precursor shallow underplating system that originally must have extended north-west from the Hikurangi Trench for about 650 km inland to the Whangarei–Tokatoka line.

By the potash–silica method, estimates of depths[11,12] for generation of the andesites (Fig. 2) indicate that East Belt lavas consistently originated at shallower levels than those of the West Belt where the greater depth for magma sites, all lying to the west of the Stokes Magnetic Anomaly System, may be related to the presence of a thicker, older sialic basement. Estimation of magma source levels from K_2O–SiO_2 indices is validated particularly for Quaternary lavas of the Taupo Volcanic Zone (124–142 km) and the Egmont volcanoes (206–232 km) where calculated depths lie within the seismically defined profile of the underlying modern Benioff zone[13]. For calc-alkaline suites in the East Belt, shallow origins are indicated also by the general rarity of basalts and by active crustal contamination of magma sources in producing extensive rhyolites and regional hydrothermal metalliferous alteration[14,15]. When compared with this evidence, $^{87}Sr/^{86}Sr$ initial ratios[8,15] seem to be anomalous[12,16], with higher values in the apparently shallower-sourced East Belt (basalts = 0.7041–0.7044; andesites rarely = 0.7035–0.7045, commonly = 0.7050–0.7065) than in the West Belt (basalts = 0.7030–0.7038; andesites = 0.7040–0.7055). The main anomaly is not the isotope ratios, but rather that mantle-derived magmas have failed to react appreciably with the Palaeozoic, more radiogenic crust of the West Belt.

The time-lines for 3 and 2 Myr develop a more westerly trend where they cross the West Belt because of the combined effect of greater depths for those magma sources and the configuration of the regression path for the subduction zone (Fig. 3); these youngest time-lines thus make an angle of ~20° with the clearly defined regional alignment of Holocene volcanic centres in the Taupo Volcanic Zone (East Belt). In view of this geometrical relationship, the older time-lines (21–5 Myr) similarly could have been divergent to the strike of the subduction surface which, at all stages of retreat, possibly approximated the trend of the Taupo Volcanic Zone.

Southeastward movement of the volcanic front, as measured along the East Belt by time-lines 21, 17, 3 and <2 Myr, shows that the rate of migration was not regular (Fig. 2). Initially, at the commencement of subduction regression, migration between time-lines 21 and 17 Myr proceeded at a rate of 27.5 km Myr^{-1} and the intervening region was subjected to pronounced tensional tectonism that produced widespread foundering of the greywacke basement (Fig. 4) and a deep basin for concurrent early Miocene flysch sedimentation[17]. In contrast, the following period of relatively slow migration at 10 km Myr^{-1}, between time-lines 17 and 3 Myr, traversed a region where the greywacke basement was extensively blockfaulted but not notably depressed, so that it persisted as a shallow marine shelf for calcareous Miocene–Pliocene sediments. Subsequent acceleration in the migration rate, at 23 km Myr^{-1} for the interval 3–<2 Myr, was again characterized by tensional collapse of the greywacke basement to depths of 5 km and accompanied by voluminous eruptions of silicic calc-alkaline volcanics in the Taupo Volcanic Zone[9,18].

Underplating of the North Island by the Pacific plate, before the early miocene, would have involved rapid shallow

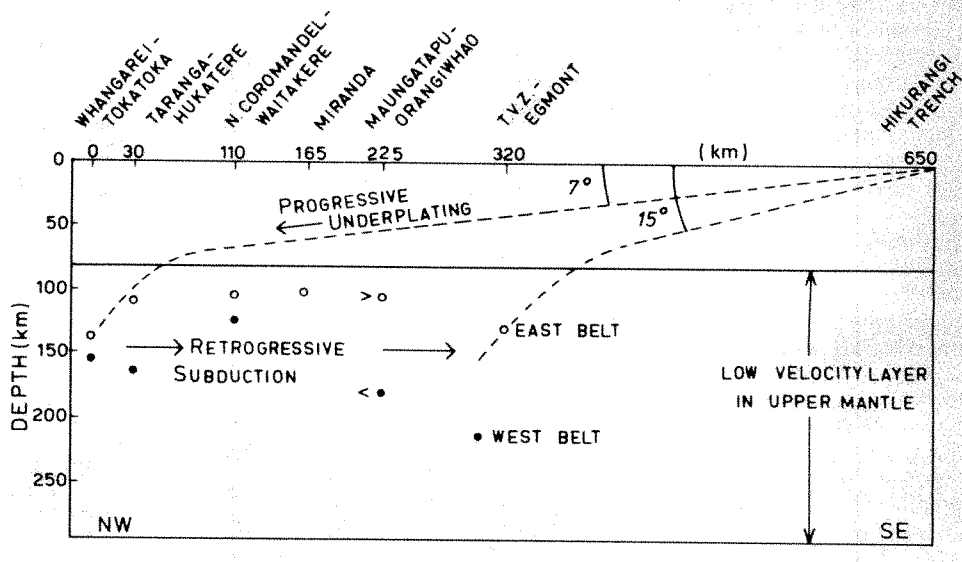

Fig. 3 SE–NW profile along the East Belt from Hikurangi Trench to Whangarei–Tokatoka (21 Myr time-line) with averaged K_{55}–K_{60} estimates of magma source depths for East Belt (○) and West Belt (●). Progressive shallow underplating during the Oligocene was followed by Miocene–Holocene subduction retrogression to the profile of the present Benioff zone[13] beneath Taupo Volcanic Zone and Egmont.

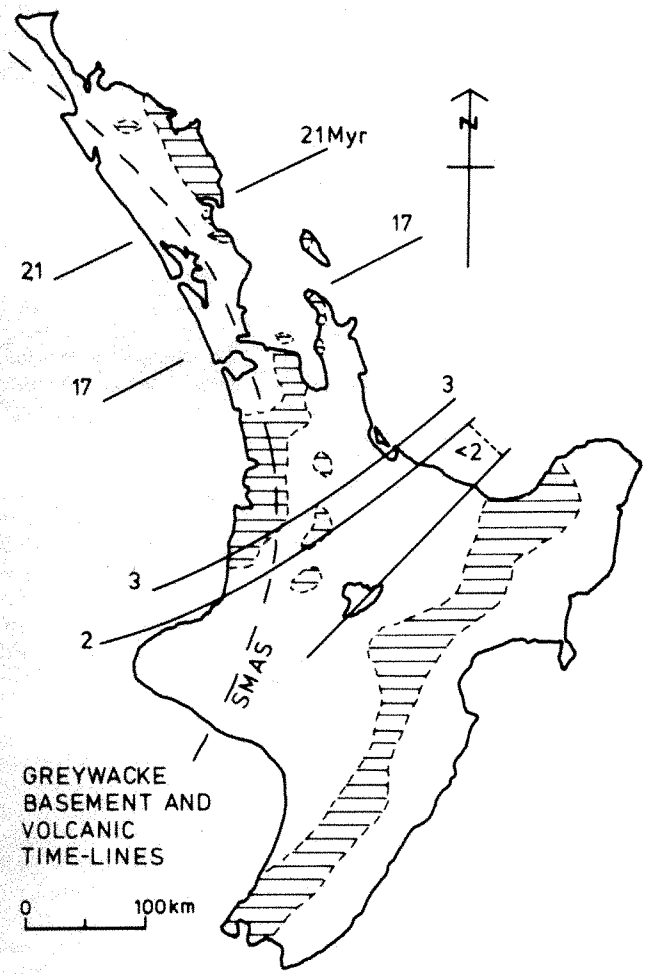

Fig. 4 North Island Mesozoic greywacke basement outcrop pattern, developed by tensional tectonic collapse within regions of accelerated subduction regression between volcanic time-lines 21–17 Myr and 3–<2 Myr.

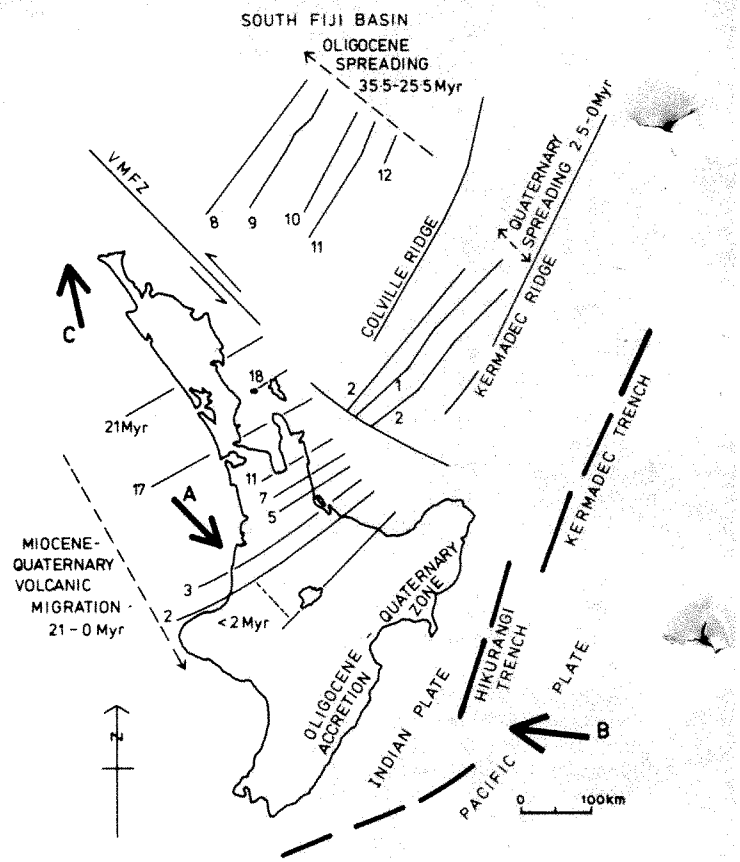

Fig. 5 Late Tertiary and Quaternary lineaments in the North Island and adjacent oceanic area. Oligocene marginal basin spreading (magnetic anomalies 12–8) produced left-lateral displacement along the Vening Meinesz Fracture Zone (VMFZ), and after Neogene quiescence was followed by Quaternary spreading (anomalies 2–1) between the Kermadec and Colville Ridges[7]. Arrow A shows Oligocene motion of North Island (Indian plate) relative to the South Fiji Basin. Arrow B is indicative of various directions within the west quadrant for absolute motion of the Pacific plate from Oligocene (anomaly 13) to Holocene, and arrow C is the present absolute motion vector for the North Island[22,25,26].

subduction not accompanied by volcanic activity for a distance of 650 km from the Hikurangi Trench to the Whangarei–Tokatoka line, a tectonic style which is similar to the amagmatic Laramide event in the western Cordillera of North America[19]. The geometry of the underplating process can be achieved by assuming a low initial trajectory of 7° (Fig. 3) which implies a rapid rate of convergence between the upper plate and the subducting slab, and a buoyant strong mechanical coupling between the two plates[20,21] which is supported by the presence of an accretionary prism of scraped-off Oligocene–Quaternary marine sediments on the landward side of the shallow Hikurangi Trench (Fig. 5). Marginal basin spreading during the Oligocene (35.5–25.5 Myr) caused offset of the North Island towards the south-east, relative to the South Fiji Basin[7], in opposition to the general westerly direction of motion at that time for the Pacific plate[22], thus enhancing the velocity of convergence at the subduction interface. This 10-Myr period of accelerated convergence, with the North Island (Indian) plate overriding the Pacific plate, could have provided the mechanism necessary for Oligocene underplating at a rate of at least 65 km Myr^{-1}. The end of seafloor spreading in the South Fiji Basin (25.5 Myr)[7] was followed by southwestward obduction of ophiolites onto the North Island (25–23 Myr)[10] and by a reduction in convergence velocity for the shallow subducting slab which, with a consequent increase in gravitational sinking rate and a steepening profile[23,24], reversed its mode at 21 Myr from north-west directed progressive underplating to southeastward subduction regression towards the Hikurangi Trench. The patterns for seismic activity[13] and younging of volcanic ages across the modern Benioff zone (Figs 1, 3) suggest that subduction retreat towards the south-east still continues.

A late Devensian ice-free area and possible interglacial site on the Isle of Lewis, Scotland

Donald G. Sutherland

Department of Geography, University of Edinburgh, Drummond Street, Edinburgh EH8 9XP, UK

Michael J. C. Walker

Department of Geography, St David's University College, Lampeter, Dyfed SA48 7ED, UK

At the time of the last glacial maximum the last Scottish ice sheet has been considered by some[1,2] to have extended to the continental shelf edge (Fig. 1*a*) whilst others[3,4] have suggested that there were ice-free areas in northern Scotland. No radiocarbon-dated stratigraphical evidence has been published to support either interpretation. We present here data from the Isle of Lewis establishing that the shelly deposits from the north of that island are of late Devensian age but which also show that a late Devensian ice margin lay across northern Lewis leaving part of the island ice-free. A peat, possibly of interglacial status, has been found in the ice-free area. The last Scottish ice sheet therefore did not pass beyond the Outer Hebrides and may not even have reached the north of the island chain. This evidence is also of interest to the debate on the relative expansions of the northern and southern margins of the Laurentide and Scandinavian ice sheets at the last glacial maximum[5,6], for it suggests a restricted glacial expansion of the northern margin of the last British ice sheet at the time of its greatest southerly extent.

Detailed mapping at a scale of 1:10,560 and recording of all natural sections in the north of Lewis have confirmed McCann's[7] observations that on part of the north-west Lewis coast, a raised beach occurs at an altitude of ~12 m (local OD)[8]. Along the stretch of coast marked a–a′ in Fig. 1*b* the beach is *in situ* and up to 150 m broad. Frequent cryoturbation structures at the top of the gravels together with solifluction and head deposits that rest on and partly incorporate the beach gravels establish that the beach predates at least one period of periglaciation[4,9]. The beach is best developed along the coast south of Galson and is here termed the Galson Beach. Although composed dominantly of material derived from the local Lewisian gneisses, the beach also contains frequent red and purple sandstone clasts that diminish in abundance southwards. The present study has also confirmed that along section a–a′ of the coast the beach occasionally overlies a till which rests on a wide (up to 150 m) rock platform[4,7,9] at an altitude of ~9 m (local OD)[8].

South-west of Melbost Borve (a, Fig. 1*b*) Peacock[4] noted that the gravels of the Galson Beach were overlain by, or incorporated in, a till and he suggested that the late Devensian limit of Outer Hebridean ice occurred in this vicinity. North-east of South Dell (a′, Fig. 1*b*) the complex shelly glacial drifts can also be observed to overlie Galson Beach deposits. At Bad an Fhithich (BF, Fig. 1*b*) beach gravels (which may be an erratic) have been reported[4,7] to overlie till although at the same locality stratified beach cobbles and sands resting *in situ* on bedrock are truncated by and overlain by till.

Detailed mapping of the shelly glacial deposits indicates that only one phase of glacial activity is represented. Complex glacitectonic structures and large erratics of marine clays and gravels have given rise to Baden-Powell's[10] interpretation of two glacial phases with an intervening period of interglacial marine deposition. These glacial deposits terminate abruptly on their southern margin and this limit can be traced across north Lewis to a major drift ridge up to 30 m high that extends for over 6 km to the south-southeast to reach an altitude in excess of 110 m (Fig. 1*b*). North and east of the ridge are extensive glacial deposits, areas of dead-ice terrain and a sequence of meltwater channels trending north-northwest.

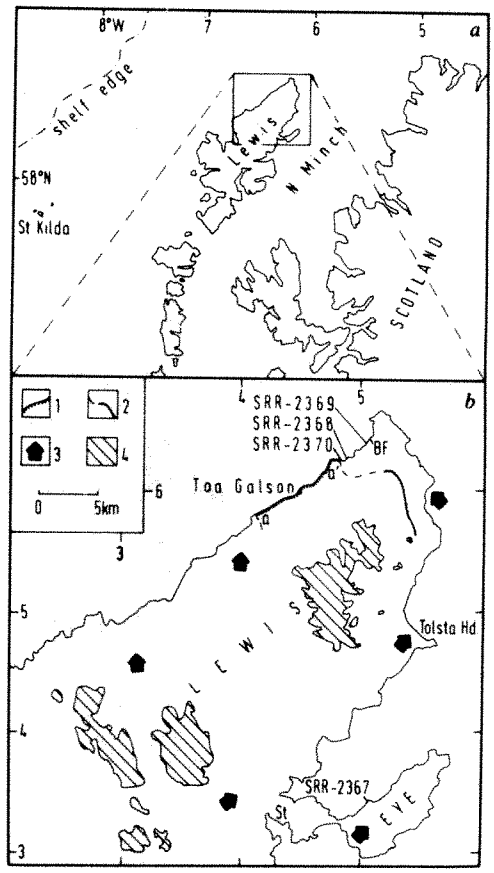

Fig. 1 *a*, Location of Lewis and *b*. *b*, Northern Lewis. 1, Stretch of coast (a–a′) where the Galson Beach is *in situ* and not overlain by glacial deposits; 2, ice margins, continuous line representing the end moraine in north Lewis; 3, generalized directions of last ice movement; 4, land over 122 m (400 ft).

The drift ridge is interpreted as an end moraine of the last ice mass to occupy the north of Lewis and the trend of the moraine, together with the direction of slope of the meltwater channels indicates that the ice had a surface gradient from south-southeast to north-northwest. Abundant purple and red sandstone clasts in the glacial deposits are most probably derived from Mesozoic[11] sedimentary rocks that floor the North Minch close offshore and they cannot be taken as evidence for the presence of Scottish mainland ice which their original attribution to the Torridonian was thought to imply[12]. Indeed, the last ice in this area may have been no more than Outer Hebridean ice recurving round the upland of northern Lewis on to the low ground farther north.

Samples of shell debris from three localities in the middle or base of these glacial deposits (Fig. 1*b*) have been radiocarbon dated (Table 1) and all gave middle Devensian ages. The shell faunas in the glacial deposits are derived from a variety of oceanographic provinces and thus very probably represent a range of ages from the ice-free period before the last ice advance. Hence the 34,000–39,000 yr BP sample ages are likely to result from a mixture of late Devensian and middle Devensian (or older) shells. Amino acid analyses of ice-transported shells from north Lewis suggest a late Devensian age (D. Q. Bowen, personal communication), supporting this interpretation. The evidence therefore indicates that the last glaciation in the north of Lewis was during the late Devensian. Expansion of the Outer Hebridean ice cap during the late Devensian is also indicated by the date on the ice-transported shells from Garrabost on the Eye Peninsula (Fig. 1*b*, Table 1), the last ice movement there as determined by carry of local erratics being from south-west to north-east.

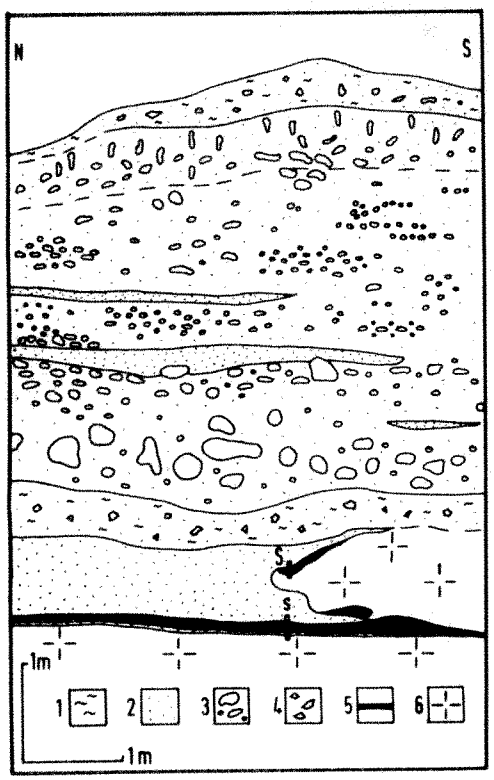

Fig. 2 Section south of Toa Galson. 1, Silt and clay; 2, sand; 3, rounded boulders and cobbles; 4, angular pebbles and gravel; 5, peat; 6, weathered or decomposed bedrock. Note cryoturbated upper ~75 cm of beach gravels. Samples for pollen analysis taken from locations marked S.

The establishment of the latest glacial event in the north of Lewis as being late Devensian in age and the stratigraphical evidence that the Galson Beach underlies or is incorporated within these glacial deposits implies that the stretch of coastline a–a′ (Fig. 1*b*) was ice-free during the late Devensian. A wave-eroded section at the front edge of the raised rock platform ~100 m south of Toa Galson (Fig. 1*b*) is particularly significant in this context, because there a peat that postdates the formation of the raised rock platform and the glaciation of this part of the coast, but predates the deposition of the Galson Beach, has been found. The stratigraphy is shown in Fig. 2.

The peat has been distorted and partly eroded by a slump of decomposed bedrock that is contemporaneous with the overlying medium-coarse iron-stained sands. Here we term the main peat body as the lower peat, Site A, the uppermost disturbed peat lens is the upper peat, Site A and a peat lens that occurs several metres farther south in the section is Site B. Between the iron-stained sand and the beach gravels is a layer of angular locally-derived clasts in a silty-sand matrix that shows minor silt lenses and weak lamination that are typical of solifluction.

Samples for pollen analysis were removed from the peat and adjacent sediments (Fig. 2) and the spectra recorded in the three peat lenses are shown in Fig. 3. In the main peat body (lower peat A) the lower samples are dominated by Gramineae and Cyperaceae but Cruciferae, *Plantago* spp., *Rumex* and *Saxifraga* are consistently represented. An open, floristically-diverse grassland is suggested with wetter areas providing a habitat for the sedges and certain species, possibly, of the Umbelliferae. With continued accumulation of the peat there is a steady increase in Ericaceae (including *Empetrum*) pollen which suggests a progressive change in the local vegetation and in the upper part of the peat the pollen spectra imply an acid heath vegetation interspersed with grassland communities. *Empetrum nigrum* is generally considered to be an oceanic species[14,15] and the change in the pollen spectra may reflect increasingly oceanic conditions with soils becoming leached and base-poor. Throughout the pollen profile there are low percentages of arboreal pollen, principally *Pinus*, although *Picea*, *Betula*, *Alnus* and *Abies* grains were also recorded. These are considered to have been derived by long-distance transfer and, with the possible exception of small areas of *Salix* and *Juniperus* scrub, the environment is interpreted as being essentially treeless.

Plant macrofossils were poorly preserved in the peat, leaf fragments of *Sphagnum imbricatum* being found in the lower part and *Viola* seeds occur throughout (P. Hulme, personal communication). Undifferentiated *Viola* seeds have a wide range of occurrence during the Pleistocene[16], but *S. Imbricatum* is of greater interest. Dickson[17] indicates that in pre-Lateglacial times *S. Imbricatum* has only been recovered from interglacial deposits with the exception of one possibly-derived attribution to the Anglian.

The upper surface of lower peat A is clearly erosional but the basal sample of the overlying sand was found to be polleniferous. This revealed a pollen spectrum very similar to the base of lower peat A. As some, if not all, of the pollen grains in this sample may have been derived from erosion of the peat no environmental change may be interpreted from this single sample. The pollen spectra from upper peat A and from site B (Fig. 3) are very similar to those from the upper part of lower peat A with a strong Ericaceae (and *Empetrum*) component. These analyses confirm that the peat lens was originally more extensive and has been eroded and disturbed by the subsequent events at the site.

A sample was removed for radiocarbon dating from the upper part of lower peat A. The sample was split into three fractions

Table 1 Radiocarbon dates on ice-transported marine shells from Lewis

Site	Laboratory no.	$\delta^{13}C$ (‰)	^{14}C age (yr BP)
West Dell Sands	SRR-2368	(o) +2.3	$37,070^{+970}_{-860}$
		(i) +2.3	$34,470^{+720}_{-660}$
Traigh Chumil	SRR-2369	(o) +1.2	$39,850^{+1270}_{-1100}$
		(i) +1.9	$39,500^{+1270}_{-1100}$
Peicir	SRR-2370	(o) +1.6	$37,320^{+1130}_{-990}$
		(i) +1.4	$35,630^{+1520}_{-1270}$
Garrabost	SRR-2367	(o) +1.6	26,300±320
		(i) −3.0	23,000±230

Pretreatment for all these samples consisted of discarding 25% by weight of the bulk sample by acid hydrolysis with the remaining carbonate being divided into equally sized 'outer' (o) and 'inner' (i) fractions by further acid treatment.

Table 2 Radiocarbon dates on buried peat layer at Toa Galson

Laboratory no. SRR-2365.

Fraction	$\delta^{13}C$ (‰)	$d^{14}C$ (‰)	^{14}C age (yr BP)
(a)	−29.3	−1000.9±0.7	>47,150
(b)	−29.2	−1000.8±0.8	>46,640
(c)	−29.7	−1001.1±1.9	>39,100

Fraction (a) was composed of ≥125 μm material that was acid washed in 2M HCl; fraction (b) consisted of <125 μm material that was soluble in 0.5 KOH; and fraction (c) was the residual <125 μm material following the alkali treatment. Fraction (b) should relate to humic acid contamination and fraction (a) should contain the coarse parts of any modern rootlets that may have penetrated the peat. The acid wash was to remove any carbonates that may have been precipitated in the peat.

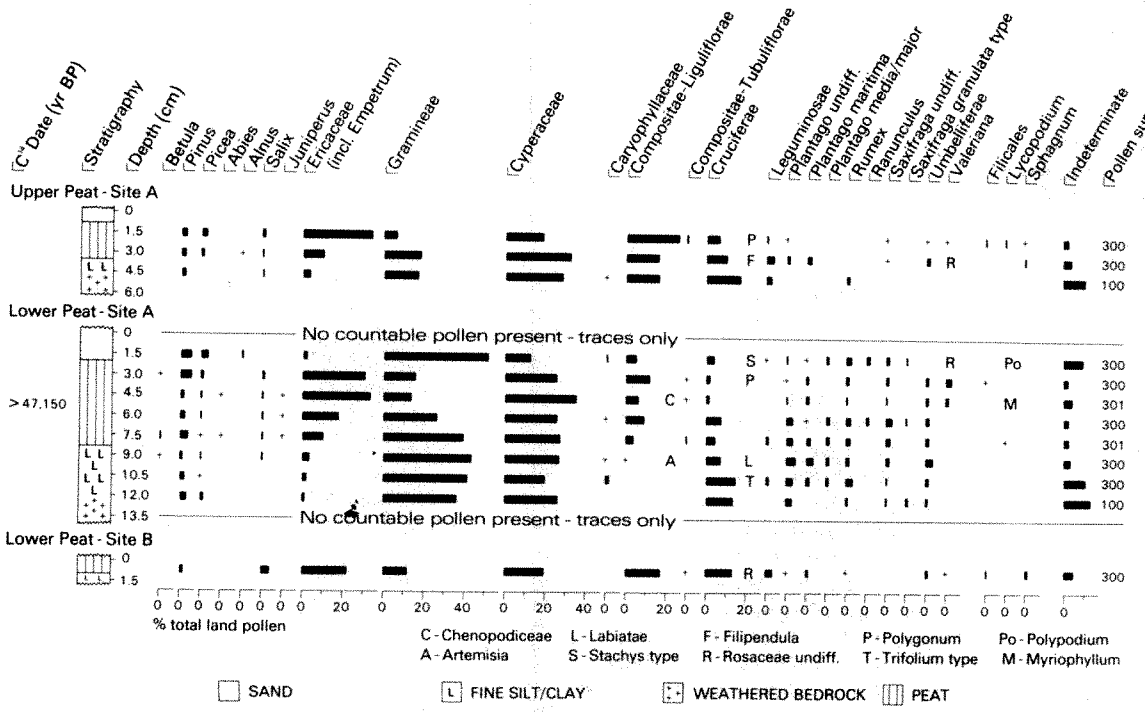

Fig. 3 Percentage pollen diagram from Toa Galson. Samples for pollen analysis were prepared using conventional procedures[13], except that residues were passed through microsieves (aperture 10 μm) to concentrate pollens and spores. Pollen preservation was good in the peat layers but in the minerogenic sediments large numbers of corroded and amorphous grains were found.

following a procedure designed to isolate the possible contaminants (carbonates, organic acids, modern rootlets). Details of the pretreatment and the radiocarbon results are given in Table 2. The agreement between all fractions indicates minimal contamination and a sample age of >47,150 yr BP.

The essentially treeless environment that has typified the northern and western islands of Scotland during the Flandrian and presumably previous interglacials and interstadials poses considerable problems in assessing the status and correlation of pre-late Devensian pollen-bearing sediments. Two other such sites are known from the Outer Hebrides, Tolsta Head[18,19] and St Kilda[20] (Fig. 1). As both these sites are associated with finite radiocarbon ages and have significant differences in their pollen spectra from that of Toa Galson, the sites are not thought to be the same age. Farther afield, however, there are certain similarities between the Toa Galson pollen profile and that from Sel Ayre, Shetland[21] where a vegetational development from grass and fern dominated communities to dwarf-shrub heaths dominated by Ericaeous shrubs, including *Empetrum*, was recorded. The local environment was treeless and the Sel Ayre site was assigned an interglacial age on the basis of inblown tree pollen and tentatively ascribed to the Ipswichian. The progressive changes of vegetation at Sel Ayre were suggested to represent an interglacial cycle in a treeless environment and if this model is correct then the Toa Galson peat may tentatively be assigned an interglacial status. Such an interpretation is in agreement with the occurrence of macrofossils of *Sphagnum imbricatum*, the floristic diversity of the grassland communities, the occasional thermophilous inblown tree species and the radiocarbon age. There is, however, no evidence that allows the site to be ascribed to a particular interglacial.

Models of the last ice sheet showing Scottish ice extending to the continental shelf edge depict the north of Lewis as being covered by 1,000–1,500 m of ice[1,2] but our evidence demonstrates that part of this area was actually ice-free. This implies a relatively restricted late Devensian glaciation along the north-west margin of the Scottish ice sheet, the ice perhaps extending no more than 100 km from the major northern Scottish mainland ice shed. Yet at this time the ice sheet reached the Midlands of England, south-west Wales and southern Ireland. In recent years there has been considerable discussion as to the relative expansions of the northern and southern edges of the Laurentide and Scandinavian ice sheets at the last glacial maximum[5,6]. In contrast to the traditional view of synchronous glacial expansion, a 'minimalist' school has suggested that the northern margins had a relatively restricted glaciation at the time of maximum southerly advance. We suggest that a similar north–south contrast typified the late Devensian British ice sheet and palaeoclimatic models that seek to explain the north–south contrasts of the larger ice sheets must also be capable of explaining a marked climatic gradient across the more southerly British ice sheet.

We thank Dr D. D. Harkness of the NERC Radiocarbon Laboratory, East Kilbride for the radiocarbon analyses. A grant from the Carnegie Trust for the Universities of Scotland towards the cost of the fieldwork is gratefully acknowledged.

Interpretations of the magnetostratigraphy of the Hadar hominid site, Ethiopia

T. J. Schmitt

14005 Cove Lane no. 204, Rockville, Maryland 20851, USA

A. E. M. Nairn

Department of Geology, University of South Carolina, Columbia, South Carolina 29208, USA

As part of an investigation to determine the age of the hominid-bearing strata of the Hadar Formation of Ethiopia we have determined the magnetostratigraphy of two separate sections of the strata. Two major zones of reversed polarity occur within the predominantly normally magnetized sequence, one at the top and the other in the middle. There are difficulties with the absolute age determinations of volcanic units within the strata which result in uncertainties in correlating the Hadar magnetostratigraphy with the standard magnetic reversal time scale. The age of the upper part of the section is established by the BKT-2 tuff at ~2.8 Myr (refs 1–4). The K–Ar dating of the Kadada Moumou basalt which lies in the middle of the sequence yields variable results ranging from 3.1 to 3.6 Myr (refs 1–4). Regional geochemical[5] and biostratigraphical[6] studies suggest the younger age for the Kadada Moumou basalt. We show here that this is also the age that results in the most consistent interpretation of the observed magnetostratigraphy of the formation, which is that the Hadar Formation was deposited during the Gauss Normal epoch and that the two reversals represent the Kaena and Mammoth events within that epoch.

The Hadar Formation is exposed in a badlands topography along the Awash River valley to the south-west of the town of Mille (Fig. 1*a*). As the beds of the Hadar Formation are horizontal or dip gently and only minor faulting is present, continuous stratigraphical sections can be sampled along the main wadis. Two major sections were sampled (Fig. 1*b*) along the Kada Hadar drainage (called the camp section) and along the Ounda Hadar drainage (called the Ounda Hadar section).

Details of sampling and laboratory procedure are given elsewhere[2,7]. Samples in the camp section were spaced at 0.5-m stratigraphical intervals, the Ounda Hadar section was sampled at more widely spaced intervals, the lower part with a large and variable interval of up to 3 m and the upper part at a 1-m interval. The natural remanent magnetization (NRM) varied, in the range of 1–50 mA m^{-1}. All samples were progressively demagnetized in alternating fields. The NRM directions of magnetization were variable; normal and reversed directions were found as well as an appreciable number of intermediate directions; the intermediate directions gradually disappeared during the progressive demagnetization. The directions of magnetization of some samples did not stabilize until high fields were applied (50–75 mT, Fig. 2*b*).

The cleaned magnetic declination of the camp section samples are shown in Fig. 2*a* in stratigraphical order with the previously published upper part of the Ounda Hadar section. The data for the camp section differ from previously presented data[2,7] in that alternating field demagnetization was continued to higher fields. The higher field demagnetization better defines the reversed intervals (see Fig. 2*b*). The comparison of the two sections is very favourable in that the fine scale of variation in declination between the two sections matches well. Although there are normal directions of magnetization within both reversals which are quite similar in both sections, their origin is not certain.

There are few radiometric data to tie the observed polarity sequence to the standard magnetostratigraphical scale because there are only two horizons in the Hadar Formation which can be used to establish the age of the formation[1–4]; these are the BKT-2 tuff and the Kadada Moumou basalt. Other volcanic horizons have large detrital components or excess argon is suspected rendering them unsuitable for age determinations.

The age of the BKT-2 is interpreted as 2.88 ± 0.08 Myr, based on several K/Ar age determinations and fission track data from zircons[1–4]. However, the age of a Kadada Moumou basalt is not clear. Repeated K/Ar analyses do not converge on a single age and age estimates show a very strong correlation with petrology. Walter[3] identified three varieties of the basalt identified as A-1, A-2 and B type basalts yielding K/Ar ages of 2.7–3, 3.2–3.4, and 3.6 Myr respectively.

The type B basalt is presently represented by only one hand sample and although the age is probably quite reliable, because it is represented by only a single sample and because its chemistry is different from the A types, it is necessary to consider a possible interpretation that it is a xenolith from an older flow, or that it contains excess argon. There are problems with the type A basalts also, for they show a correlation between observed alteration and age. As might be expected, the A-1 type basalts which are the most altered give the youngest ages. However, Walter *et al.*[4] prefer the 3.6-Myr age for the basalt. Figure 3 shows two possible interpretations of the polarity data as indicated by the various ages which may be attributed to the Kadada Moumou basalt.

The original interpretation[1,2,7] assumes the A-1 age, 2.7–3.0 Myr, for the basalt. The two reversed zones are then correlated with the Kaena and Mammoth events within the Gauss normal epoch. This interpretation is consistent with the reversed magnetization of the Kada Moumou basalt.

A second interpretation (not shown) assumes the A-2 age, 3.2–3.4 Myr, for the basalt. This requires the upper reversed zone to represent the Kaena and Mammoth events. This is inconsistent with the lower reversal, in that the lower reversal which includes the reversed basalt would correlate with the base of the Gauss normal epoch. For this correlation to be true, the Kadada Moumou basalt and lower reversal would have to be the result of remagnetization. There is no evidence of remagnetization of the basalt and consequently this possibility is rejected.

The third interpretation which assumes a type B age for the basalt, 3.60 ± 0.15 Myr, requires the upper reversed zone to contain both the Kaena and Mammoth events. The lower reversal would correlate with the top of the Gilbert reversed polarity epoch. While satisfying most of the polarity data, the extent of the normal section below the reversed horizon poses a problem.

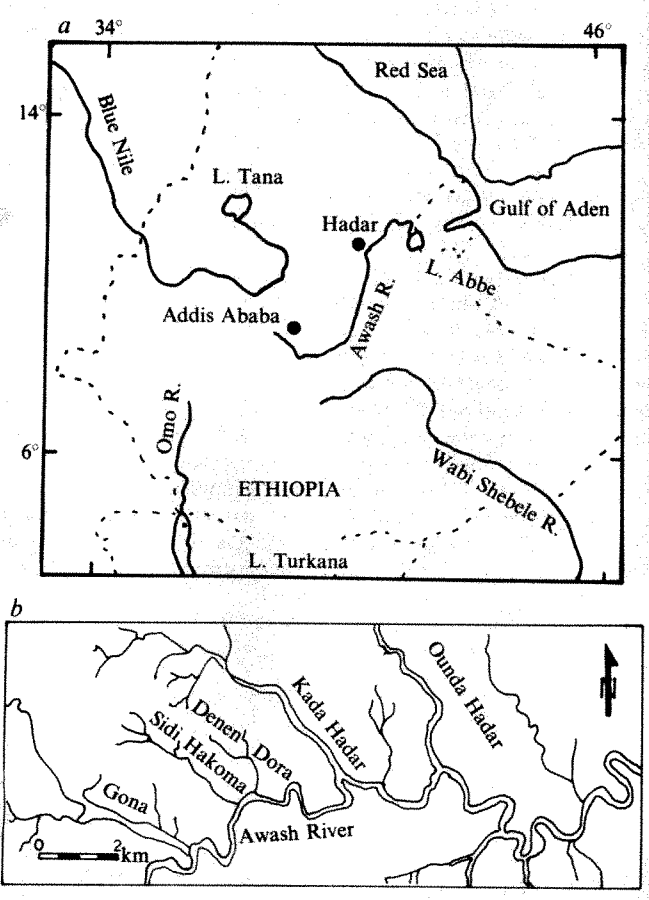
Table 1 Sedimentation rates implied by the different interpretations of the Hadar Formation

Stratigraphical interval	Magnetic interval	Stratigraphical thickness (m)	Interpretation 1 Age range (Myr)	Interpretation 1 Sedimentation rate (cm kyr^{-1})	Interpretation 3a Age range (Myr)	Interpretation 3a Sedimentation rate (cm kyr^{-1})	Interpretation 3b Age range (Myr)	Interpretation 3b Sedimentation rate (cm kyr^{-1})	Depositional environment
Middle KH	Upper reversal	35	2.92–3.01	39	2.92–3.15	15	2.92–3.15	15	Deltaic fluvial
Lower KH Middle DD	Middle normal	40	3.01–3.05	100	3.15–3.40	16	3.15–3.40	16	Deltaic fluvial
Middle DD Upper SH	Lower reversal	25	3.05–3.15	25	3.40–3.80	6	No data	No data	Lacustrine
Upper SH Base	Lower normal	70	3.15–3.40	28	3.80–3.90	70	No data	No data	Deltaic fluvial lagoonal base

To account for the absence of a reversed interval between the Cochiti and Nunivak events either the normal magnetization at the base of the section consists of the Cochiti event (which would require a very high sedimentation rate), interpretation 3a, or the base of the section has been remagnetized, interpretation 3b, which is shown.

The net sedimentation rates through the section can be used to examine the internal consistency of the various age interpretation for the basalt. Table 1 shows the net sedimentation rates for the stratigraphical section implied by the interpretations 1, 3a, and 3b. The sedimentation rates were calculated by dividing the thickness of the magnetozones by the duration of appropriate zone as given by Mankinen and Dalrymple[8]. The thicknesses are approximate in that the thickness of the Hadar Formation is variable in the study area. Most of the variation, however, is due to variation in thickness of the SH unit. The depositional environment of the Hadar Formation is given in the right column of Table 1; details of the development of the sedimentary model are given elsewhere[9,10]. The sedimentation rates in a fluvio–lacustrine environment such as the Hadar Formation may be expected to be variable. However, the broad trends in sedimentation should vary with the sedimentary environment. During periods of fluvio–deltaic activity when large amounts of sediment are being deposited in the nearshore regions and deltaic facies are dominant, then relatively high sedimentation rates are possible (though unconformities could also be present). When there was a major transgression of the lake and lacustrine environments dominated, the sedimentation rate could be expected to be lower.

Interpretation 3a implies a sedimentation rate of only 6 cm kyr^{-1} for the Upper SH to Middle Denon Dora but a minimum sedimentation rate of 70 cm kyr^{-1} for the lower part of the section. While an unconformity could be present which could lower the apparent sedimentation rate, there is no evidence of



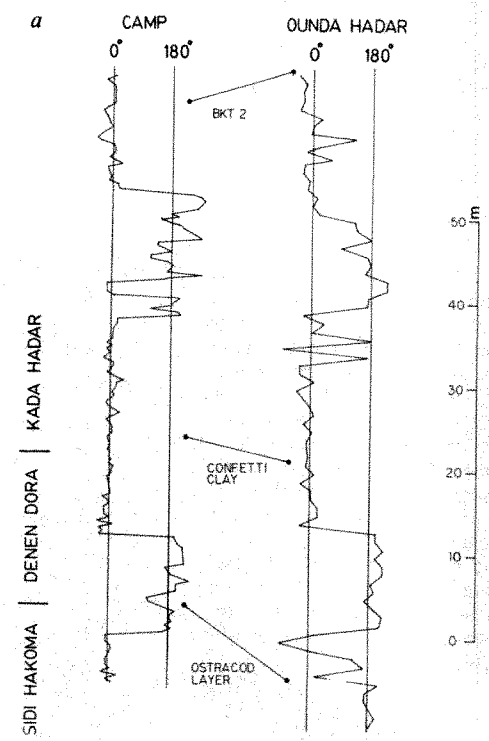


Fig. 1 Setting of the Hadar hominid site. *a*, Location of Hadar with respect to major drainage. *b*, Location of stratigraphical sections with respect to local drainage of the Hadar region.

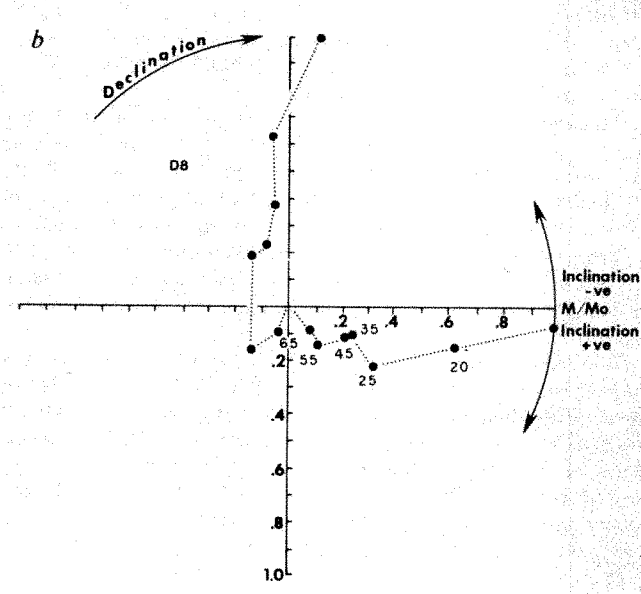

Fig. 2 *a*, Magnetic declinations plotted against stratigraphical position of the upper half of the Hadar Formation. Declinations are plotted from the upper half of the camp and Ounda Hadar sections. The lower half of both sections are normally magnetized. The magnetic directions are cleaned to 500 or 750 Oe. If the samples were still changing direction between 350 and 500 Oe then they were demagnetized to 750 Oe. The previous presentation of the camp section[2,7] was at lower demagnetization stages. *b*, Stable end point diagram of a representative sample of the Hadar Formation. The declination and inclination of magnetization of the sample are plotted against normalized intensity of magnetization at each demagnetization stage. The demagnetization stages are listed in the diagram in mT. The first stage is NRM. A significant change in direction of the sample (a reversal) with high demagnetization fields is shown.

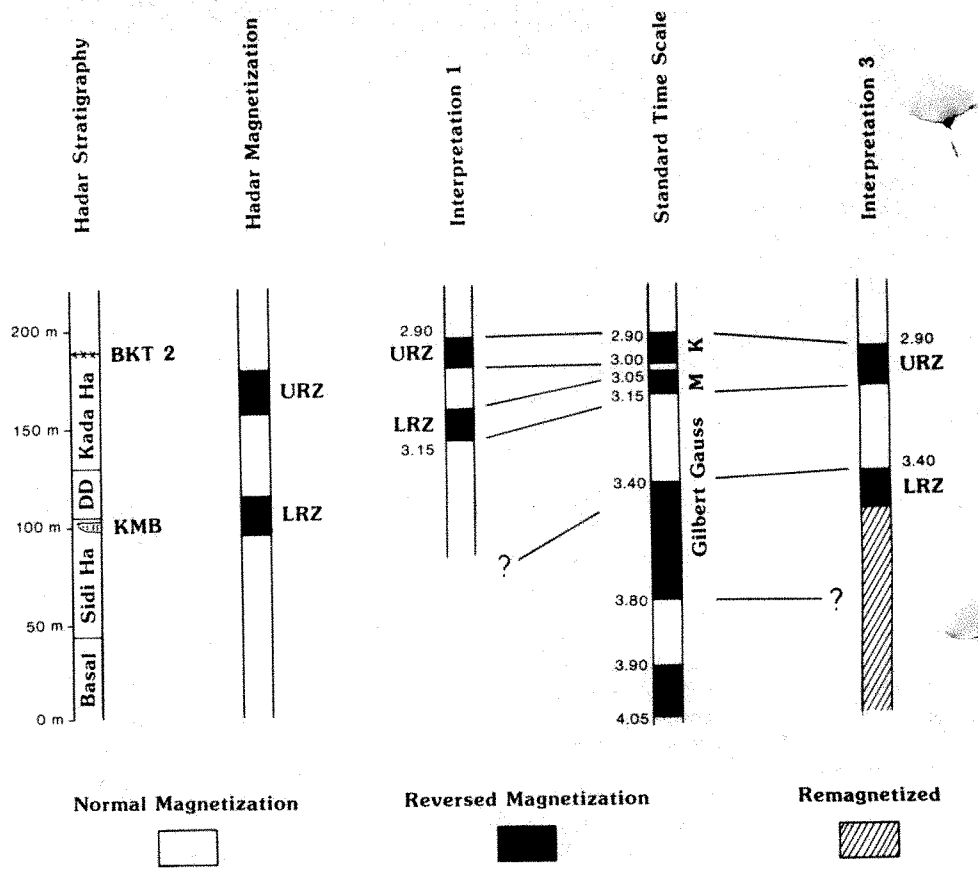

Fig. 3 The various interpretations of the Hadar magnetostratigraphy are shown with the 'standard' magnetostratigraphy and stratigraphy of the Hadar Formation. The standard ages for the Gauss and Gilbert are from ref. 8. K, Kaena; M, Mammoth events. The Hadar magnetization is from this and previous papers. The interpretations are as in the text. The schematic of the Hadar Formation is modified from Walter and Aronson[4]; the thicknesses of the Hadar Formation are variable, the thicknesses noted here are approximately the thicknesses of the members of the 1975 camp section.

a time gap large enough to reduce the rate to that of 6 cm kyr^{-1}. Also, the implied minimum sedimentation rate of 70 cm kyr^{-1} is considerably higher than the sedimentation rate implied for similar facies elsewhere in the section.

Interpretation 1 implies a relatively high sedimentation rate (40–100 cm kyr^{-1} for the fluvio–deltaic periods and low rate (2.5 cm kyr^{-1}) during the lacustrine period. The 28 cm kyr^{-1} rate for the base and SH is a minimum rate and thus not inconsistent with the higher rates for the similar facies higher in the section.

Interpretation 3b implies a sedimentation rate of 15–16 cm kyr^{-1} for the upper part of the section. The sedimentation rate for the lower part is indeterminate due to interpreted remagnetization.

In the Omo Valley of southern Ethiopia and northern Kenya and the basins along Lake Turkana in Kenya there are hominid-bearing fossiliferous strata temporally equivalent to the Hadar Formation. Further constraints on the age of the Hadar Formation can be made by comparison of the Hadar Formation with those formations. Brown[5] and Boaz *et al.*[6] compared the Hadar Formation with the Omo and Turkana facies by geochemical and palaeontological means, respectively.

Brown compared the minor and trace elements chemistry of the Sidi Hakoma Tuff of the Hadar Formation with the Tula Bor Tuff of the Koobi Fora Formation, and its equivalents, Tuff B of the Shungura Formation, and Tuff U-10 of the Usno Formation. They are strikingly similar. He took this to indicate that they were the result of the same volcanic eruption. The correlation is consistent with the magnetostratigraphy. These tuffs are assigned to the lowest normal of the Gauss Normal epoch; thus the stratigraphical correlation implies that the lower reversed zone of the Hadar Formation is the Mammoth event, between 3.05 and 3.15 Myr.

Boaz *et al.*[6] attempted a biostratigraphical correlation of the Hadar Formation with the Shungura and Usno formations. They compared the evolutionary stage of individual genera and species and made a statistical correlation of the Hadar fauna with a set of a faunal assemblages from the age range 2.9–3.15 Myr. They found the Hadar Formation most similar to the Usno Formation, which has the older of the two faunas. They concluded that the biostratigraphy was consistent with the geochemical correlation made by Brown[8]. There are, however, some constraints on biostratigraphy, for the age of the Hadar Formation is from 2.9 to at least 3.15 Myr and perhaps 3.6 Myr. That is, the Hadar age range covers both of the standards compared and although most of the Hadar fauna are from the Denon Dora member, the correlation was based on the full faunal list.

The consistency of the polarity sequence of the two separate magnetostratigraphical sections after cleaning strongly suggests that the sequence is a true record of the magnetic field at the time of deposition of the strata and that there is minimal remagnetization. The age of the upper part of the section is reliably established as about 2.8 Myr. Using that as an anchor point the uppermost reversed zone is correlated with the Kaena event and the middle reversed zone is correlated with the Mammoth event. This is consistent with regional geochemical[5] and biostratigraphical[6] correlations. The net sedimentation rates implied by the correlation are consistent with the A type basalt ages and supports the original[1,2,7] age estimates for the Hadar Formation and its important fossils.

Adult-obtained pyrrolizidine alkaloids defend ithomiine butterflies against a spider predator

Keith S. Brown Jr

Laboratório de Ecologia Química, Departamento de Zoologia, Instituto de Biologia, Universidade Estadual de Campinas, C.P. 6109, Campinas, São Paulo 13.100, Brazil

Ithomiine butterflies, the original distasteful models in neotropical mimicry complexes, show warning coloration and are usually rejected by both vertebrate and invertebrate predators[1–4]. Based on co-evolutionary theory[1,5–7] and the Danainae–cardenolide example[7], this protection has been ascribed to toxic compounds sequestered by larval Ithomiinae from their host-plants, usually poisonous Solanaceae[8–10]. However, although the giant tropical orb spider *Nephila clavipes* cuts out field-caught Ithomiinae from its web[4,11] it readily eats freshly emerged adults. Solanaceae toxins are not found stored in adult Ithomiinae[6,11] and when applied to the palatable[1] butterfly *Biblis hyperia* do not induce rejection behaviour in *Nephila* (Table 1). I show here that the protection of ithomiines against this abundant predator is due to dehydropyrrolizidine alkaloid monoesters and their *N*-oxides, absent from Solanaceae but sequestered by these butterflies as adults from flowers (mostly Eupatorieae) and decomposing foliage (mostly Boraginaceae)[11–13]. These compounds are also important in the reproduction of the Ithomiinae[11,14].

Complete species lists and analytical results are given in ref. 11. Over 2,500 individual butterflies in Danainae (3 genera, all 6 South American species) and Ithomiinae (32 of 34 Brazilian or 51 neotropical genera, 82 species) were analysed and shown to store PAs. In most individuals, 50–65% of the PA was *N*-oxide and 2–5% dihydropyrrolizine (type *k*), with ketones (types *j* or *l*) also detected. Unspecified amounts of PAs (*e*+*g*), previously found in *Oleria* and *Hypomenitis*, were considered as precursors of pheromone *m*, isolated from male hairpencils of *Ithomia*, *Pteronymia*, *Godyris*, *Hypomenitis* and *Greta*[14]. A total of 42 species of larval foodplants (in 19 genera), extracted and fractionated in parallel with their herbivores, always gave negative assays with *Nephila* except with very heavy loads on the *Biblis* (>10 mg; became negative upon dilution). Over 400 blind bioassays were performed using over 100 *Nephila*, in triplicate (if +) or duplicate (if −), with code-numbered total extracts (Ex) or fractions (1-neutral; 2-alkaloidal; 3-polar; 4-apolar). Letters for chemical compounds refer to Fig. 1, plus *n*-other alkaloid classes, *o*-phenolic glycosides, *p*-pungent oils, *q*-cardenolides, *r*-lower terpenes and *s*-alkaloid *N*-oxides. Ithomiinae and Solanaceae tribe letters and numbers are in approximate evolutionary order[8,10]; note the apparent lack of 'parallel diversification' type co-evolution between the genera of these herbivores and their host-plants[5,10,11].

* Eggs of these species showed from 0.1% (*Methona*) to 9% of dry weight as PAs.

† Mature larvae of these taxa are aposematic in colour-pattern.

‡ Recently emerged adults of 13 species in these 10 genera, of both sexes, reared in the laboratory from eggs or larvae and denied access to PAs, were consumed without hesitation by *Nephila* which in many cases had just cut out a field-captured adult of the same species and sex. Mattocks–Bingley assay[25,26] showed no PAs in these and in many other recently emerged adults.

§ Flowerheads of several abundant Brazilian species of *Eupatorium* contain 1–4% of a single isomer of PA (*k–o*) and the corresponding *N*-oxide, and thus represent important new sources for these compounds, some of which are now in advanced clinical testing as antitumour agents.

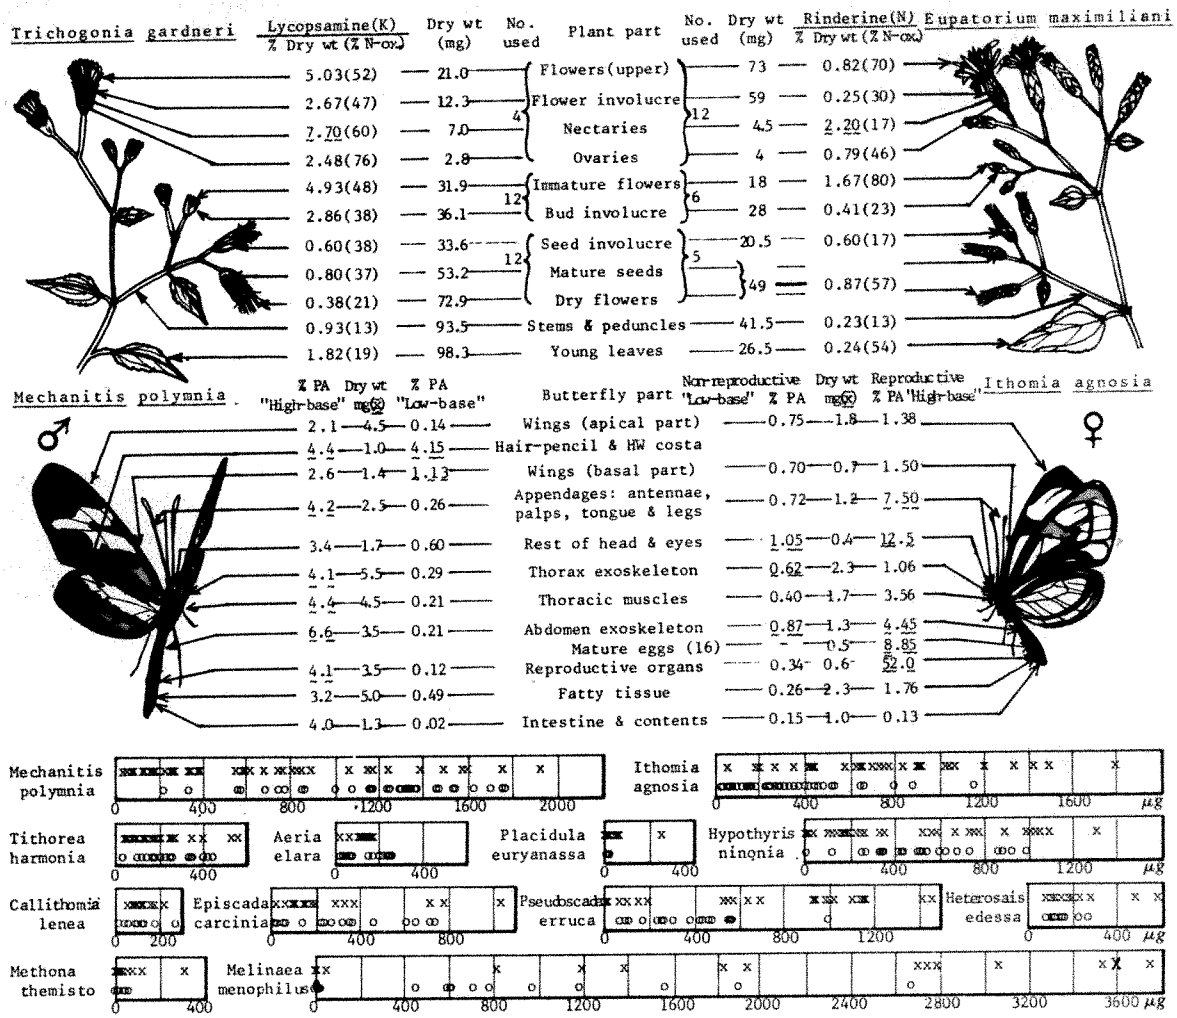

Fig. 2 Distribution of PAs in two species of Eupatorieae commonly visited by Ithomiinae (upper), and (lower) within and between individual adults of typical Ithomiinae (see Table 1 for further data and chemoassay details). High-base non-reproductive and low-base reproductive females of *Ithomia agnosia* were also encountered. The thorax tended to show low *N*-oxide content (<50% of PA) and detectable dihydropyrrolizines in both species dissected, while abdominal contents usually had low PA in non-reproductive (winter dry season) individuals. The variation in total PA between adults in a given population (males as crosses on upper line, females as circles on lower in each graph) was random or polymodal, indicating a wide 'palatability spectrum'[7]. Individuals near the lower end, usually very young, would be true 'automimics' in the population and should be readily eaten by *Nephila* (Fig. 2). The patterns suggest opportunistic accumulation of alkaloid by each individual as various sources become available to the population, up to a maximum of over 13% of dry weight (at least in *Napeogenes*, *Ithomia* and *Pteronymia*; *Scada* males captured near *Eupatorium* flowers averaged over 13% and one showed over 20%), or 5.8 mg (in a male *Melinaea mneme*). Recently emerged adults (laboratory-reared or field-captured) showed no PA; a highly positive correlation was found in males, but not in females, between PA content and estimated age. Typical spreads, concentrations and male–female patterns in PA storage are shown by *Ithomia*. A few genera (*Tithorea*, *Placidula*, *Callithomia*, *Heterosais*, and especially *Methona*) show low accumulation in adults. *Tithorea*, *Aeria*, *Mechanitis*, *Rhodussa* and *Hypothyris* may show greater average storage of PAs in females than in males in some populations, but highest concentrations are always found in reproductively active males. Males attracted to baits (PA sources) and females attracted to displaying males showed low concentrations, suggesting an 'appetite effect'. In a notable case of a mating pair of *Melinaea menophilus*, the male was about to transfer 1.7 of his 3.6 mg of PA in a spermatophore (a small sac with less than 10% of his dry weight) to the virgin female who contained no PA. Other courting or mating males of seven genera analysed showed similar channelling of PA into spermatophores (up to 23% of dry weight or 50 times the concentration found in the rest of the organism), supporting a suggestion by L. Gilbert that females, rarely found on PA sources, get most of their alkaloid from males during mating. As they mate opportunistically and frequently, and place much of their PA on the eggs they lay, their content does not correspond so well with age.

Many pharmacological, physiological and ecological activities of dehydropyrrolizidine alkaloids (PAs) are known[15]. Danaine butterflies (sister-group to the Ithomiinae[16]) and arctiid moths sequester PAs from larval foodplants, or as adults obtain them from the same sources as do the Ithomiinae, using them as physiological regulators, pheromone precursors and defence substances[12,13,17–20]. In Danainae that store cardenolides erratically from larval food[21,22] PAs have often been suggested as alternate predator–defence compounds[13,21–24]. In *Utetheisa* (Arctiinae), larval-sequestered PA diesters protect adults against *Nephila clavipes*[18]. Some male Ithomiinae were suggested to use adult-sequestered PAs as hairpencil pheromone (Fig. 1*m*) precursors[12–14], but these butterflies have usually been assumed to sequester Solanaceae toxins for defence[1].

Methanol–water extracts, prepared by rapid vigorous homogenization of fresh leaves or flowers of larval and adult foodplants and fresh butterflies, were separated into medium-polarity neutral, alkaloidal and highly polar fractions, containing different classes of secondary compounds (Fig. 1). Further extraction with ethyl acetate gave an apolar fraction. Extracts and fractions were characterized by chromatography and ^{1}H-NMR spectra, and bioassayed with large populations of *Nephila* in ithomiine 'pockets'[2,3]. A small amount (corresponding to that extracted from 0.5–1.5 butterflies, 0.5 g fresh leaf of larval foodplant or 0.05 g fresh leaf or flowers of adult food), in aqueous solution or suspension, was applied with a soft brush onto the

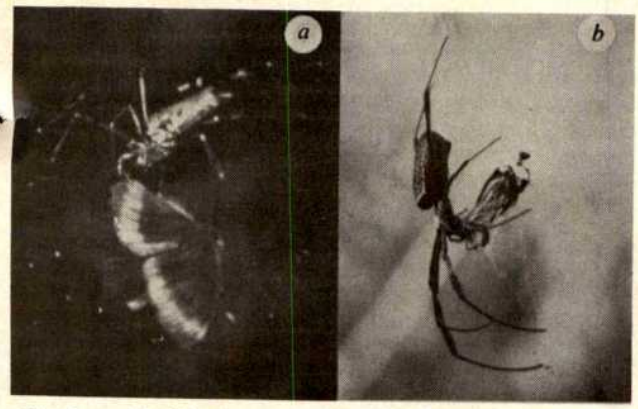

Fig. 3 *a, Nephila clavipes* cutting out a *Biblis hyperia* treated externally with the total MeOH–H_2O extract of one *Mechanitis lysimnia* adult. *b, Nephila* eating a freshly emerged *Pseudoscada erruca* adult, reared from the egg on *Cestrum laevigatum.*

body and wing bases of the common nymphaline *Biblis hyperia.* This was thrown into the web of a mature, non-satiated *Nephila*, which either readily ate the *Biblis* or cut it out (Fig. 3).

All *Biblis* treated with Solanaceae leaf extracts or fractions, or apolar or neutral fractions of Ithomiinae, like newly emerged adult Ithomiinae except *Aeria* (Apocynaceae-feeder), were accepted by *Nephila* (Table 1). In contrast, all total extracts and alkaloidal or polar fractions of field-captured Ithomiinae and their principal food sources caused *Nephila* to cut *Biblis* out just like intact wild Ithomiinae. All active extracts and fractions contained one or more PA monoesters (Fig. 1*e–i*), free or *N*-oxides. When freshly emerged adult Ithomiinae were fed pure PA *N*-oxide (0.3 mg) they became unpalatable to *Nephila* after about 1 h.

The distribution of PAs in Ithomiinae and food sources, measured by a modified Mattocks–Bingley assay[25,26], corresponds to their ecological and reproduction roles. The Eupatorieae, often pollinated by Ithomiinae[12], show highest concentrations in the flowerheads and especially nectaries, while the butterflies concentrate the alkaloids in the tegument (where the predators will immediately sense them), reproductive tissues and eggs (Fig. 2).

Most Ithomiinae found on PA sources are males[11,12]. In chemoassay, males of most genera show a broader range of PA content and higher extreme accumulation than females (Table 1, Fig. 3). Reproductively active males channel up to half their total PA into spermatophores that are transferred to females, who accept multiple matings and may obtain much PA in this fashion (Fig. 2).

Thus freshly emerged adult Ithomiinae, which unlike many Danainae and Arctiidae bear no accumulated toxins from larval foodplants, must find in their environment the PAs used in defence and reproduction. This necessity determines many chemical, physiological, behavioural, and morphological traits of the adult insects and of the plants they pollinate. Selection probably favours the obtaining of such essential compounds from a source stabilized by mutualism, rather than from the solanaceous larval foodplants, whose diversified chemical leaf constituents are constantly changing in response to the antagonistic setting and do not offer protection against *Nephila*, a major potential predator of Ithomiinae.

I should like to thank João Vasconcellos-Neto, José Roberto Trigo, Silvana Aparecida Henriques, Renata S. Carvalho Dias, John Edgar and Thomas Eisner for help with this work; and Miriam Rothschild and Lincoln Brower for criticisms of this letter. Fibre type composition of single motor units during synapse elimination in neonatal rat soleus muscle

Wesley J. Thompson & Lee A. Sutton

Department of Zoology, University of Texas, Austin, Texas 78712, USA

Dan A. Riley

Department of Anatomy, Medical College of Wisconsin, Milwaukee, Wisconsin 53226, USA

Skeletal motor neurones innervate the specialized 'types' of fibres comprising most mammalian muscles in a characteristic fashion: each motor neurone forms a 'motor unit' by innervating a set of fibres all of the same type[1–4]. Because the type expression of adult muscle fibres is plastic and apparently controlled by their innervation, each motor neurone is thought to impose a common type differentiation on all the fibres in its motor unit[4–6]. However, the situation in developing muscles cannot be this simple. Muscle fibres in neonates receive synaptic input from several motor neurones and achieve the adult, single innervation only after a period of 'synapse elimination'[7,8]. Despite this polyneuronal innervation, differentiated fibre types are present in neonatal muscles[9–14]. This means either that the motor neurones polyneuronally innervate fibres in a random fashion and type expression is not determined by innervation or that the polyneuronal innervation is ordered in such a way that each fibre could receive unambiguous instructions for type differentiation. We have investigated these possibilities here by determining the fibre type composition of motor units in neonatal rat soleus muscle. We find that even during the time of polyneuronal innervation each motor neurone confines its innervation to largely one of two fibre types present in the muscle. Therefore, some mechanism during early development segregates the synapses of two groups of soleus motor neurones onto two separate populations of soleus muscle fibres.

We examined the soleus of Wistar rats at two postnatal ages—at 8 days, when every fibre is innervated by at least two motor neurones, and at 16–17 days, by which time synapse elimination has resulted in virtually every fibre being singly innervated[8]. In agreement with previous work[9–11], we found two distinct fibre types in soleus cross-sections stained for myofibrillar ATPase activity (Fig. 1). At both ages muscles showed a mosaic of lightly and darkly stained fibres. Because these neonatal muscles contain a number of novel embryonic and neonatal myosin

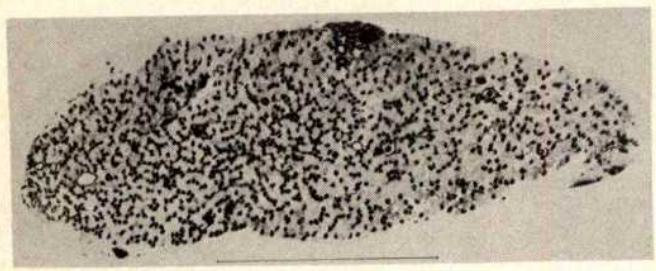

Fig. 1 Cross-section of a 16-day-old rat soleus muscle stained for myofibrillar ATPase activity after alkaline preincubation at *p*H 10.4 according to the method of Guth and Samaha[34]. Two muscle fibre types are visible, termed light and dark according to staining intensity. Scale bar, 1 mm.

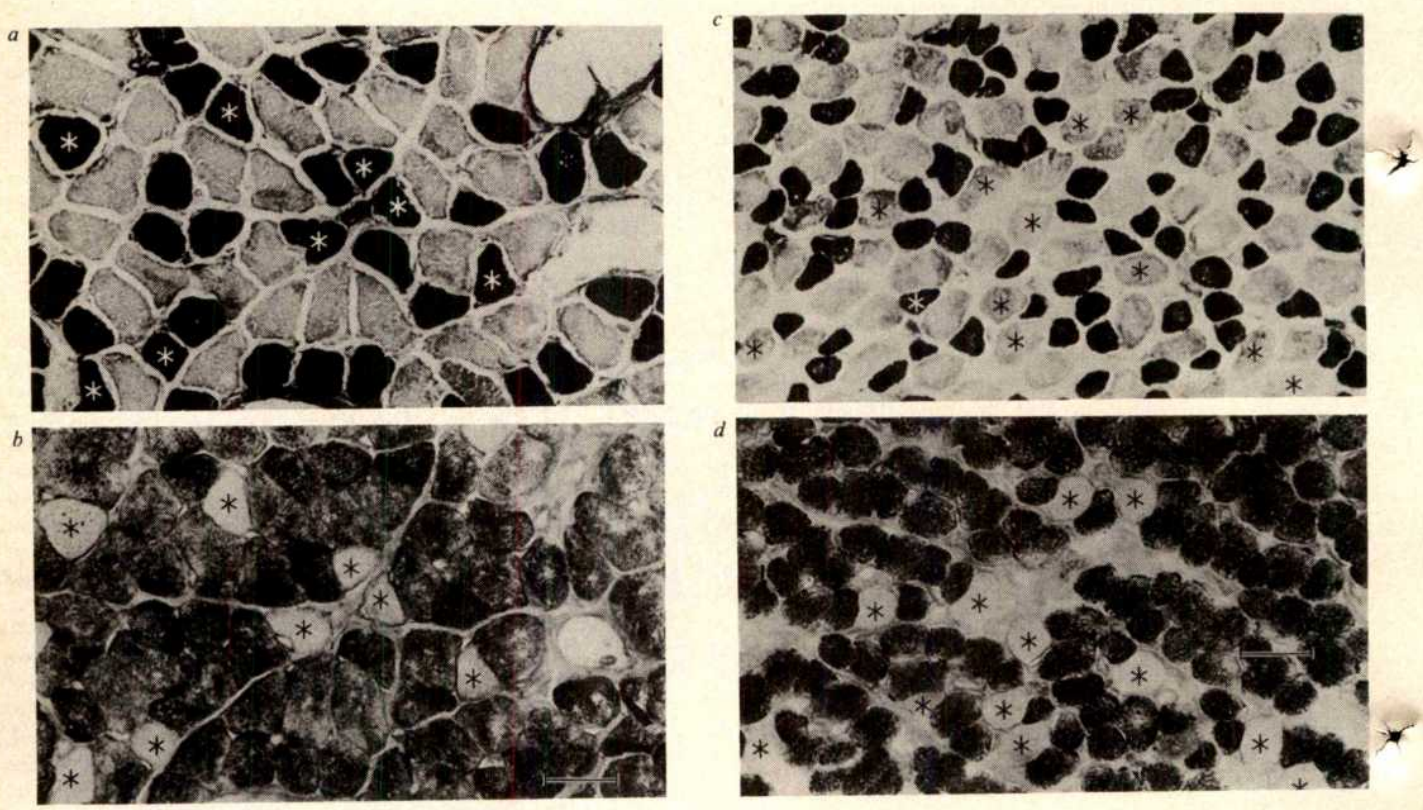
isozymes[13,15–17], there is some uncertainty as to the exact adult fibre types to which each staining pattern corresponds. Although the light fibres presumably become type I fibres and the dark fibres type IIA fibres[9,10], we refer to these fibre types as 'light' and 'dark' based on staining intensity. Similar light/dark differentiation was seen at both ages (Figs 2*a*, *c*, 3*a*). Moreover, the total number of fibres and the proportion of each type appeared unchanged, despite the loss of over 50% of the synaptic connections in the muscle between 8 and 16–17 days.

To determine how single soleus motor neurones innervate these two fibre types, we used the glycogen depletion technique[18–20] to mark the fibres in a motor unit. The basis of this method is that stimulation of a single motor neurone activates the fibres comprising its motor unit and, in conditions of muscle anoxia, forces these fibres to utilize their glycogen stores. By staining muscle sections for glycogen, these fibres can be identified by their absent or weak coloration.

The procedures outlined by Kugelberg[19] were used for isolating and stimulating a single soleus motor axon in anaesthetized rats. Fibres in the motor units of stimulated axons were easily recognized in sections stained with the periodic acid-Schiff method[21] (Fig. 2*b*, *d*). Counts of depleted fibres showed that motor units at 8 days contained two to three times more fibres than those at 16–17 days (Fig. 3*b*), implying that the average muscle fibre at 8 days receives suprathreshold innervation from two or three motor neurones. These counts also offer some assurance that the depletion method is marking a large fraction of the fibres in units, as the present measurements are in reasonable agreement with estimates of motor unit size based on tension measurements (140 fibres at 16–17 days[22] and 340 fibres at 8 days[8]). Thus, glycogen depletion reaffirms the polyneuronal innervation of neonatal muscles and the decrease in motor unit size accompanying synapse elimination[8,23,24]. This decrease in unit size occurs as each motor neurone reduces the number of fibres it innervates, presumably as a result of competition among the terminals at each end plate[8].

The fibre type of each depleted fibre was determined by identifying the same fibres in two adjacent muscle sections, one stained for glycogen and the other for ATPase activity (Fig. 2). By examining complete cross-sections in this fashion, the fibre type composition of motor units was determined (Fig. 4). The striking finding is that motor units at both ages were largely homogeneous. Given the proportions of light and dark fibres present in soleus, a random innervation would be expected to yield units containing a mixture of about 55% light and 45% dark fibres. However, even at 8 days units consisted of at least 72% of one fibre type, and three of the five units examined were >90% homogeneous (Fig. 4). As motor neurones primarily innervate either only dark or only light fibres at day 8, most of the polyneuronal innervation of dark (or light) fibres must come from neurones which form motor units of the dark (or light) type. Furthermore, because of this predominance of synapses



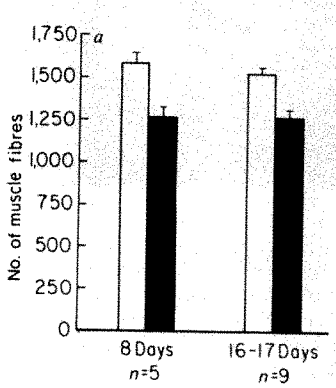


Fig. 2 Muscle cross-sections stained for myofibrillar ATPase activity after alkaline preincubation (*a*, *c*) and for glycogen (*b*, *d*). Adjacent sections stained by each method are shown for two muscles following stimulation of a single soleus motor axon. *a*, *b*, Portion of a motor unit from a 16-day-old rat. *c*, *d*, Portion of a motor unit from an 8-day-old rat. Asterisks mark glycogen-depleted fibres and the corresponding fibres stained for ATPase. Scale bars, 25 μm.

placed on 'appropriate' types of fibres, most of the synapse loss between 8 and 16–17 days occurs from appropriate as opposed to inappropriate fibre types.

The most intriguing finding is the segregation of innervation by two groups of soleus motor neurones. One obvious explanation of this segregation is a selective synapse formation between predetermined types of neurones and muscle fibres. Indeed, this type of selectivity has been previously proposed for other neuromuscular systems[25,26], and certain recent findings support the existence of some type of predetermination of fibre type[12,27–29]. Other observations, however, militate against such selectivity. First, reinnervation of adult fibre types is nonspecific and fibres mismatched with their innervation are gradually transformed in fibre type[30]. Second, the differentiation of one type of fibre (slow, type I) seems to be neurally induced, as this type is absent in muscles denervated at birth[11,27,31]. Moreover, there are certainly alternative explanations of the segregation which do not require a predetermination of muscle fibre types. In fact, the observed segregation of innervation is the result required if fibre types were to be dictated by instructions from innervating axons during polyneuronal innervation.

How might the segregation occur in the absence of predetermined fibre types? Two preexisting types of motor neurones might segregate their synapses onto separate naive muscle fibres as a result of an interaction among nerve terminals either during synaptogenesis or during a subsequent period of synapse elimination preceding 8 days. An alternative suggestion made by Rubinstein and Kelly[12] involves the timing of synaptogenesis and myogenesis: if two groups of motor neurones arrive in the muscle at different times, coinciding with separate waves of myogenesis, these neurones could be constrained to innervate different sets of muscle fibres polyneuronally. Exactly how muscle innervation becomes segregated is unknown, but it is now evident that the generation of homogeneous motor units does not await the single innervation of muscle fibres.

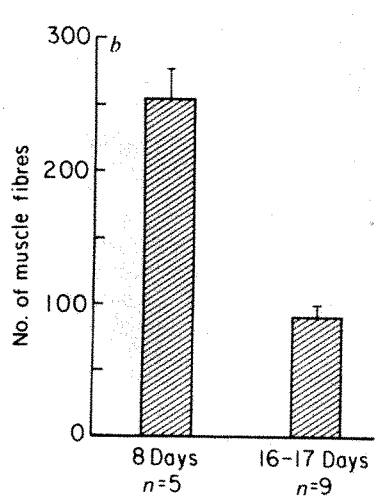

Fig. 3 Changes in muscle fibre type composition and motor unit size between 8 and 16–17 days. *a*, Number of dark (filled bars) and light (open bars) fibres found in muscles of each age. *b*, Numbers of muscle fibres comprising single motor units as determined by glycogen depletion. Vertical lines represent s.e.m.

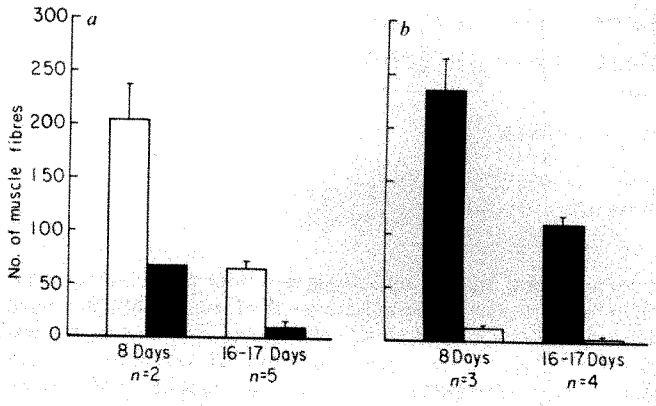

Fig. 4 Fibre type composition of motor units in soleus muscles at 8 and 16–17 days. Numbers of fibres of the dark (filled bars) and light (open bars) types are shown for motor units at each age. *a*, Units composed predominantly of light fibres. *b*, Units composed predominantly of dark fibres. Vertical lines represent s.e.m. (No vertical line appears for two units in the 8-day muscles in *a* which each contained 66 dark fibres.)

We acknowledge that H. Gordon and D. Van Essen have reached similar conclusions to those reported here by their study of the contractile properties of motor units in neonatal rabbit soleus muscle (ref. 32 and work in preparation).

This work was supported by a grant from the Searle Scholars Program of the Chicago Community Trust. We thank our colleagues for critical comments on the manuscript, J. Young for preparation of the figures, and M. Raymond for her instruction in cryostat sectioning. A preliminary account of this work was given elsewhere[33].

Is stepwise sarcomere shortening an artefact?—a response

G. H. Pollack

Center for Bioengineering WD12, University of Washington, Seattle, Washington 98195, USA

Like any other signals, optical signals from muscle fibres inevitably contain noise. The noise here is of predictable character. Because the structure of muscle is periodic, or almost so, translational movement of an illuminated fibre will inevitably give rise to a periodic noise fluctuation as striations pass across the optical field. The frequency of this fluctuation should be linearly related to the speed at which the fibre translates. By mistaking this noise component for the signal, Altringham and colleagues[1] have amply succeeded in confirming this expected relationship, but they have left unanswered the question of the source and nature of stepwise shortening. I show here that: (1) by having obtained records in conditions in which the noise dominated, Altringham *et al.* have inadvertently confused the steps with the translation-induced fluctuation; and (2) when records are obtained using a method designed specifically to circumvent the effects of translation, the steps still remain in evidence.

Consider first the authors' Fig. 1 (ref. 1). To evaluate their method of analysis, consider, for example, the record labelled '2.72 μm' in Fig. 1*b*. This record is not unlike many we have obtained and published[2,3]. How many steps are there? I identify one pause (of moderate 'quality'), and hence two steps. The authors, however, have mistakenly confused the high-frequency fluctuations superimposed on the trace for the steps. Consequently, they counted 47 instead of 2. Records such as these gave the mid- to high-frequency points on their Fig. 1*a*, drawing the authors towards the inappropriate conclusion that the step frequency was linearly related to translation velocity. Instead, what they have shown is that it is the fluctuation that is linearly related to translation velocity. Had the authors plotted step frequency instead of fluctuation frequency, the resulting scatter diagram would have led them to an opposite conclusion to the one they drew.

The authors' Fig. 2 (ref. 1) illustrates the results obtained with the phase-locked loop (PLL, striation imaging) method. Consider the first (18-4-83) of the two experiments. As waveforms for this day's experiment were not shown by the authors, I have reproduced representative samples here in Fig. 1*a*, and show comparable records taken from our recent experiments in Fig. 1*b*. Note that the noise levels are 20–50 nm and 2–3 nm respectively. A step size of 10–20 nm, characteristic of our records, would therefore be buried in their noise. The authors, once again, appear to have studied a fluctuation.

Such fluctuations have, of course, been of concern to us. The PLL method inherently generates translation-induced fluctuations[5], but we have demonstrated that with signals of reasonable quality, their amplitude remains 2 nm or less[4]. However, we have also obtained our share of records as noisy as those in Fig. 1*a* when one of a number of conditions had not been carefully controlled. Inevitably, the translation-induced fluctuation becomes the dominant feature of such records and masks the actual sarcomere shortening signal. While we ordinarily discard such records, Altringham *et al.*[1] have capitalized on them and have elegantly confirmed that the translation-induced oscillations correlate well with translation ($r = 0.999$).

In the second of the two PLL experiments, illustrated in the authors' Fig. 2*b*, Altringham *et al.* appear to be dealing with genuine sarcomere-length signals. However, their protocol ensures that the linear relationship will be found. In this second experiment, observation was restricted to a single region, while the moving end of the fibre was released at each of various speeds. Increasing the speed of release brings with it two (correlated) effects: it increases the local sarcomere shortening velocity, causing the steps to occur more frequently, and it also increases the local translation velocity. Thus, a linear relationship between step frequency and translation velocity is an inevitable consequence of their protocol. Further, since the translation velocity will increase from the fixed to the moving end, the slope of this linear relationship is not unique; it will depend on the choice of region to be studied. The particular value of slope found in this experiment is therefore without significance.

Finally, with regard to the authors' Fig. 3, we previously published essentially identical experiments except with 1,000 times higher time resolution. We showed that in regions which did not translate excessively, the first-order profile remained steady during the pause[3]. This convinced us that the pause represented a truly stationary period. Our conclusion did not imply that changes in first-order profile could not accompany the pause. Clearly, in the experiments of Altringham *et al.*, where substantial translation was an essential element in the protocol, and where only those diffraction patterns with 'less than

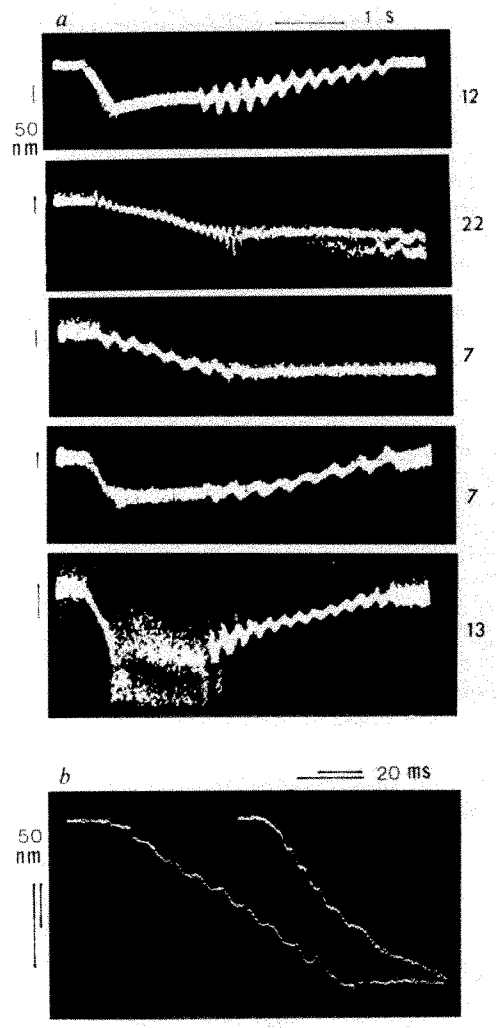

Fig. 1 Time course of sarcomere shortening measured with the phase-locked loop (PLL) imaging method. The five traces in *a* were obtained in the experiment of 18-4-83 and were kindly provided by Altringham *et al.*[1]. (These are not worst-case records; peak-to-peak noise averaged among all 20 records was 32.5 nm, in the range of the five shown here.) Time bar calibration refers to all but the third panel, which is 200 ms. The number of oscillations counted by Altringham *et al.* is given at the right of each panel. The traces in *b* are representative of those obtained in experiments on unstimulated (left) and stimulated (right) frog toe fibres in this laboratory. They illustrate the character and size of the steps that we have measured[4,15]. Note that steps of this size would probably be submerged in the noise of the upper set of records. Also note the vast differences of time scale between *a* and *b*.

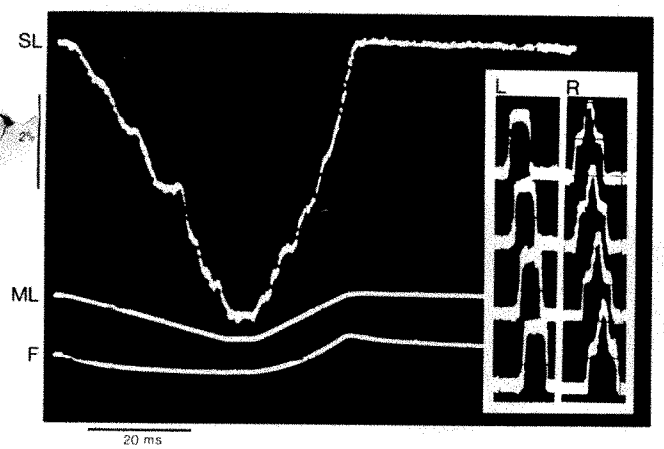

Fig. 2 Time course of segment shortening in an unstimulated single fibre of frog tibialis anterior muscle[6]. SL, segment length; ML, muscle length; F, force. Initial segment length was 515 μm. The segment is defined by the spacing between two hairs, nominally 10 μm in diameter and 80 μm in length, mounted on the upper surface of the fibre, perpendicular to its long axis. The image of the section of fibre containing the two hairs was split such that one hair was projected onto one photodiode array, while the other was projected onto a second array. A processing circuit computed the area under the image of each marker, from which the respective median locations were computed. The difference between median locations gave the segment length. Thus, the method is insensitive to translation. Of 17 fibres that gave usable segment length signals, 11 showed distinct, repeatable steps. The two inset panels show the intensity profiles of the left (L) and right (R) markers at four instants (top to bottom) spanning the longest shortening pause. They demonstrate that spurious fluctuations of intensity profile of either marker were not present, and therefore could not have given rise to an artefactual pause. Edman *et al.*[8], using a similar method, also observed pauses in some records of segment length change (see their Fig. 8).

optimum quality' could be used, the detection of such changes is not at all surprising.

Thus, by using (1) noisy PLL signals, (2) weak diffraction patterns and (3) protocols in which translation was emphasized, Altringham and colleagues have set their attention on signals dominated by noise. In so doing, they have obtained clear proof that the noise arises out of fibre translation. It is unfortunate that the superficial resemblance between the translation-induced artefact and the stepwise shortening signal has given rise to this confusion. In fact, signal and noise are quite distinct. In the optimized conditions that we have been trying to realize since our early experiments (the reverse of (1)–(3) above), patterns such as those of Fig. 1*b* have begun to emerge consistently and serve to define the phenomenon. In such low-noise records, the shortening waveform approaches a true staircase, with clear pauses and regular cascades of steps of predictably distinct size[4,15]. By contrast, the fluctuations shown in the authors' waveforms are of broadly variable size and character. The resemblance is thus only superficial.

Nevertheless, in light of the potential for confusion, we have designed a simple experiment to determine whether steps could still be observed in conditions in which the effects of translation were circumvented[6]. Using a segment-length detection method similar in principle to that developed by Gordon, Huxley and Julian[7], we have observed stepwise shortening regularly in both stimulated and unstimulated fibres (Fig. 2). Similar waveforms have been found with other segment-length methods in three laboratories (refs 8, 9 and T. Tameyasu and H. Sugi, in preparation). We conclude, therefore, that steps arise independently of translation.

The phenomenon of stepwise shortening is not easily reconciled with commonly accepted views of contraction, as the authors state[1]. This is perhaps why the challenge by Altringham *et al.* is not unique; it represents the fourth in a series, each laying claim to identification of the long-sought artefact[1,10–12]. Yet the phenomenon remains robust. It has now been observed in a variety of laboratories using four classes of methodology: laser diffraction[2,3,10,13], on line imaging of the striations[4,15], high-speed cinemicrography (ref. 14 and H. Sugi and M. Toride, in preparation), and various segment-length methods (refs 6, 8, 9 and T. Tameyasu, T. Yoyoki and H. Sugi, in preparation). Although some unsuspected artefact may yet remain, I know of no other phenomenon that has been confirmed by as many distinct methods as this.

Sir Andrew Huxley comments

Department of Physiology, University College London, Gower Street, London WC1E 6BT, UK

POLLACK says that the fluctuations illustrated in Fig. 2*b* of the article by Altringham *et al.* 'appear to be genuine sarcomere-length signals'. However, the fact pointed out by Altringham *et al.* that 'one oscillatory cycle corresponds to the translation of one sarcomere past a given point in the optical field' makes it practically certain that in this case the fluctuation is an instrumental artefact. The existence of 'noise' fluctuations of this kind is admitted by Pollack. Its origin in experiments using the PLL device is clearly seen in Fig. 1 of Pollack's ref. 4: the crude frequency signal fluctuates at one cycle per sarcomere in the image, and this fluctuation will be eliminated only if the number of sarcomeres m over which the signal is averaged is an integer (n). m depends on sarcomere length, and when $m = n + 1/2$, the peak-to-peak fluctuation in the average as the image moves across the field is $A/\pi m$, where A is the peak-to-peak amplitude fluctuation in the signal being averaged. With the values given in Pollack's ref. 4, this comes to 3.6 nm, which is close to the amplitude of the deviations from a smooth curve in Pollack's Fig. 1*b* and in Fig. 2*b* of Altringham *et al.*, both of which are taken by Pollack to represent genuine changes of sarcomere length.

These reasons for believing those fluctuations to be artefactual are not upset by Pollack's claim that 'a linear relationship between step frequency and translation velocity is an inevitable consequence of their [Altringham *et al.*'s] protocol': true, but the protocol does not ensure one cycle per sarcomere, which would be an unlikely coincidence unless the fluctuation is an instrumental artefact. Pollack's suggestion that the slope of the relationship 'will depend on the choice of region to be studied' is contradicted by the observation of Altringham *et al.* that 'the frequency of the oscillations appears to be determined only by the translation velocity of the fibre at the point observed, and not by the rate of change of sarcomere length'.

I conclude that Altringham *et al.* are right in claiming that the rather regular fluctuations often seen with the PLL method

are an artefact. The 'one pause' claimed as real by Pollack lasts for about 10 sarcomeres of fibre displacement, and may therefore be simply the consequence of a difference of sarcomere length between two regions in the fibre.

Details of the 'simple method' referred to by Pollack, with which his Fig. 2 was obtained, have not yet been published (his ref. 6 is 'in the press'), so there is no way of telling to what errors it is subject. There are many possible sources of error; for example, sideways movement of the fibre if the markers are not perpendicular to the fibre axis, or vertical movement of the fibre if the light beams used for following the two markers are not parallel to one another.

Transposition bursts in genetically unstable *Drosophila melanogaster*

Tatjana I. Gerasimova*, Lev J. Mizrokhi† & & Georgii P. Georgiev†

* N. I. Vavilov Institute of General Genetics, USSR Academy of Sciences, Gubkin str. 3, Moscow B-334, USSR
† Institute of Molecular Biology, USSR Academy of Sciences, Vavilov str. 32, Moscow B-334, USSR

A genetically unstable strain of *Drosophila melanogaster*, ct^{MR2}, which appeared in the course of hybrid dysgenesis[1], was found to contain an unstable mutation in the *cut* locus, resulting from an insertion of the mobile element *mdg4* (ref. 2). Multiple genetic events, probably resulting from transposition, were found in this strain and its derivatives[3]. We have analysed the localization of various mobile elements within the X-chromosome of the ct^{MR2} strain and its derivatives. We report here a dramatic change in the localization of mobile dispersed genetic elements *mdg1, mdg2, mdg3,* and *copia*, FB- and P-elements within the X chromosome. Up to 20 independent transposition events were detected. As the localization of mobile elements within ct^{MR2} and within each substrain is invariant, we conclude that all transpositions occurred simultaneously in one and the same germ cell. Such 'transposition bursts' may have an important role in evolution.

The genetically unstable strain ct^{MR2} gives rise to several stable and unstable ct^+ reversions and novel *ct* mutations[1,3]. These are frequently accompanied by other unstable mutations. All *ct* mutations including *ct* lethals contained *mdg4* in the 7B region of the X chromosome[2].

Using *in situ* hybridization with polytene chromosomes, we have analysed the localization of different mobile elements in the X chromosome of the ct^{MR2} strain (Figs 1–3). Larvae were examined at various times, in particular almost immediately after obtaining the ct^{MR2} strain and 2 years later. In all cases, the localization of mobile elements was exactly the same (the number of individual larvae analysed totalled 20). Thus, different mobile elements including *mdg* (*copia*-like elements), P-elements and FB-elements, have rather stable localizations. However, the analysis of novel substrains derived from ct^{MR2}, as a result of transposition event(s) in *cut* or other loci, reveals a dramatic change in the localization of mobile elements (Figs 1, 2). The two most extensively studied examples are shown in Fig. 1. The substrains analysed were ct^+ revertants which occurred simultaneously with unstable mutations at the *singed* or *white* loci. All mobile elements showed evidence of transposition, with their appearance at new, and disappearance from old, sites. In the case of $ct^{MR2} \rightarrow ct^+sn^{MR2}$, 20 simultaneous transposition events were counted, and 12 were found for the $ct^{MR2} \rightarrow w^{MR1}$ *ct* mutation.

It is important to stress that all individuals of the new derivative strains possess the same distribution of mobile elements—this means that all transposition events occurred simultaneously in the same germ cell. Had different transpositions occurred at different stages, there would be no homogeneity within the strains.

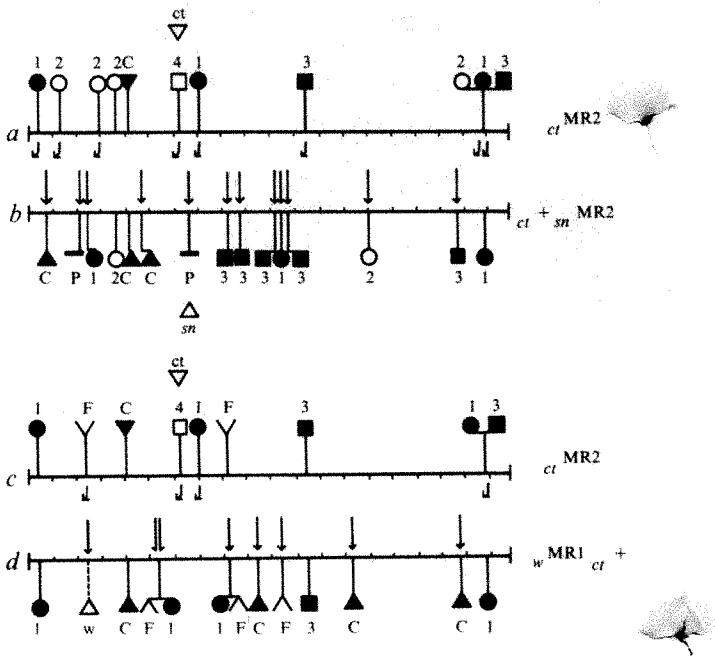

Fig. 1. Schematic presentation of the results obtained for *in situ* hybridization of ct^{MR2}, ct^+sn^{MR2} and $w^{MR1}ct^+$ X chromosomes with different probes. *a, c*, Distribution of hybridization sites along the ct^{MR2} X chromosome; *b*, that of the ct^+sn^{MR2} X chromosome; *d*, that of the $w^{MR1}ct^+$ X chromosome. In *a, b* the hybridization was performed with *mdg1* (1), *mdg2* (2), *mdg3* (3), *mdg4* (4), *copia* (C) and P-element (P); in *c, d* with *mdg1, mdg3, mdg4, copia,* P-element and FB-element (F). Triangles indicate the location of mutations characteristic of the strains analysed. Arrows show transposition events: the loss of mobile elements (⇃) and their insertion (↓). Here and in the other figures, the 20 divisions on the line representing the X chromosome indicate the 20 major divisions of the chromosome on a Bridges map, the centromere being to the right. The strain ct^{MR2} remained unstable for 1.5 years, thereafter the transposition rate decreased, but later on increased. The strain was homozygous with respect to the X chromosome. ct^+ reversions and novel unstable mutations were observed in the males of the ct^{MR2} strain. To obtain the corresponding substrains, we used one of two methods. (1) The mutants were crossed with females bearing attached X chromosomes. Further, only the X chromosomes of male larvae were analysed. (2) The mutants were crossed with females possessing an X chromosome with a multiple inversion *FM4*, y^{31d}, sc^8dm *B* that excluded crossing-over. In this case, novel substrains homozygous with respect to the X chromosome (originating from ct^{MR2} X chromosome which has avoided crossing-over) were obtained. This made it possible to analyse both male and female X-chromosomes.

Figure 2 shows two other examples of multiple transpositions in the X chromosome of ct^{MR2} derivatives. In these cases, the ct^{MR2} mutation did not change, but a new unstable mutation occurred at the *garnet* (*g*) or *Bar* (*B*) locus. As the ct^{MR2} mutation was conserved, the *mdg4* remained in the 7B region. However, in both cases, several transpositions were found for other *mdg* elements and for FB-elements. Thus, the loss of *mdg4* from the 7B locus is not necessary for the induction of transposition. It should be pointed out that, in $ct^{MR2}g^{MR1}$, a *g* mutation seems to be induced by a *copia* insertion, as g^+ reversion always coincides (four cases were tested) with a loss of *copia* from the 12BC region.

We have also analysed several other ct^{MR2} derivatives for localization of *mdg1* or *copia* (Fig. 3). It is clear that almost always two to four transposition events occur in the X chromosome.

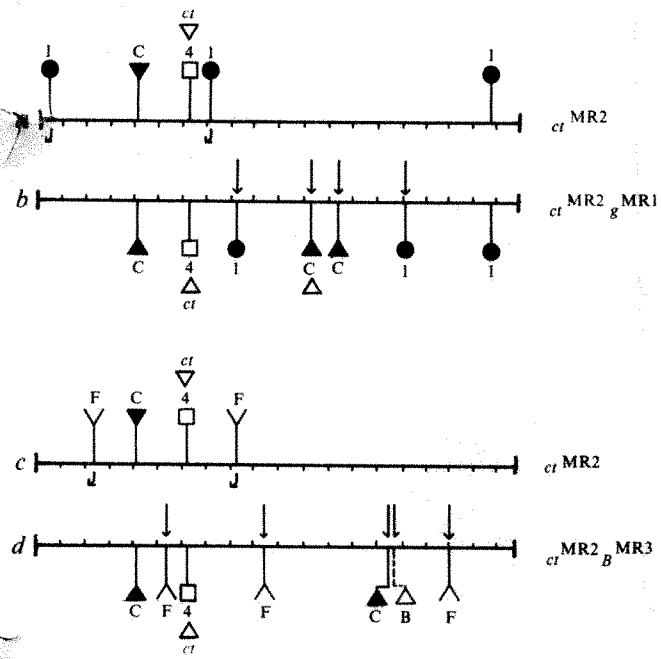

Fig. 2 Schematic presentation of the results obtained for *in situ* hybridization of ct^{MR2}, $ct^{MR2}g^{MR1}$ and $ct^{MR2}B^{MR3}$ X chromosomes with different probes. *a*, *c*, Distribution of hybridization sites along the ct^{MR2} X chromosome; *b*, that of the $ct^{MR2}g^{MR1}$ X chromosome; *d*, that of the $ct^{MR2}B^{MR3}$ X chromosome. In *a*, *b* the hybridization was performed with *mdg1*, *mdg4* and *copia*; in *c*, *d* with *mdg1*, *mdg4*, *copia* and FB-element. Designations are the same as in Fig. 1. The method used to isolate the substrain was as described in Fig. 1 legend.

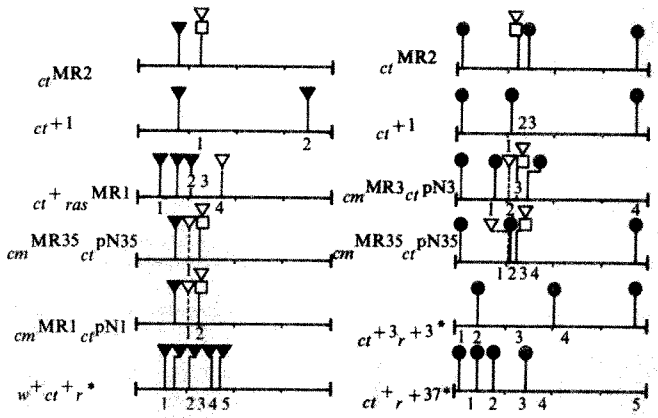

Fig. 3 Results of *in situ* hybridization of the X chromosomes from different ct^{MR2} derivatives with *mdg1* and *copia*. Most of the substrains appeared as the result of a mutation in ct^{MR2}. Those marked by asterisks were obtained from the $ct^{MR2}r^{MR1}$ substrain (which, in turn, originated from ct^{MR2}). The numbers represent the number of the transposition event. Designations are the same as in Fig. 1. Triangles indicate the locations of mutations in the individual strains.

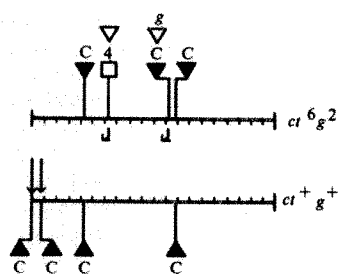

Fig. 4 Comparison of the distribution of *mdg4* and *copia* in the stable and destabilized ct^6g^2 strain and the ct^+g^+ double revertant obtained from ct^6g^2. Designations are the same as in Fig. 1.

The ct^{MR2} strain is not the only strain in which multiple transpositions can be observed in few germ cells. The ct^6g^2 strain (from the Mid-America *Drosophila* stock centre, Bowling Green State University), destabilized by a cross with the P-factor-containing strain *MRh12/Cy* (ref. 4), is another example. In the destabilized strain, a reversion to the g^+ and ct^+ type occurs at a rate of $\sim 10^{-3}$. In half of the cases, a double ct^+g^+ reversion takes place. The X chromosomes from stable and destabilized ct^6g^2 strains contain four *copia* sites (Fig. 4); different individuals possess the same distribution of *copia* sites. In the offspring of one ct^+g^+ revertant, however, one *copia* site was lost and two new sites were accepted (Fig. 4). Thus, three transposition events concerning only one *mdg* element occurred in the same germ cell.

We conclude, therefore, that in *Drosophila melanogaster* strains destabilized by hybrid dysgenesis, transpositions occur in only a few germ cells, but are numerous in these particular cells. 'Transposition bursts' have occurred in these cells.

Transposition bursts involve at least three major types of mobile elements: (1) mobile dispersed genes (*mdg*) or *copia*-like sequences[5,6]; (2) foldback sequences[7]; and (3) P-elements[8]. Hence, all of these may be mobilized by a similar mechanism.

The total number of transposition events should be at least an order of magnitude greater than that determined in our experiments. We analysed the locations of only six different families of mobile elements and in only one chromosome. Even then, up to 20 simultaneous transposition events were detected; thus, the total number may be several hundreds.

Transposition bursts seem to occur only rarely in germ cells ($\sim 10^{-3}$) but this value may be an underestimate, as we expect that the insertion of a mobile element would occasionally be lethal and the respective germ cells or embryos would not survive. In fact, the homozygous ct^{MR2} strain is characterized by a high rate of appearance of sex-linked lethals[1].

The question arises as to which factors control multiple transposition. In our system (ct^{MR2}), P-factor seems to be an important component[2,3]. However, although the P-factor is present in all cells of a given organism, transpositions occur in only a few of them. Probably some other trigger mechanism exists.

The saltatory character of transposition may have a significant role in evolution. It is well known that the insertion of mobile elements is an important factor in spontaneous mutagenesis[9]. Therefore, transposition bursts should lead to simultaneous multiple mutagenesis, creating an organism that differs in many feautres from its parents. One of the problems in theories of evolution is how to explain the appearance of new complex properties requiring several independent genetic changes, each of which is not selectively advantageous—transposition bursts may provide the answer. Multiple mutations could occasionally create such complex features, which may then be retained by selective pressure.

In our system, transpositions occur at a premeiotic stage and, as a result, novel mutants sometimes appear in clusters[1]. This may help changed genomes to survive in further generations.

Finally, transposition events can sometimes lead to gross chromosomal rearrangements. Thus transposition bursts may also assist in creating the reproductive isolation of a new substrain, the process having a key role in speciation.

We thank Drs D. Finnegan, G. Rubin and S. Potter for the clones containing *copia*, P-factor and FB-elements, Dr M. M. Green for the *MRh12/Cy* stock, and Dr M. Ashburner for critical reading of the manuscript.

Control of tubulin gene expression in the parasitic protozoan *Leishmania enriettii*

Scott M. Landfear & Dyann F. Wirth

Department of Tropical Public Health, Harvard School of Public Health, Boston, Massachusetts 02115, USA

The life cycle of parasitic protozoa of the genus *Leishmania* consists of two morphologically distinct forms[1]: (1) amastigotes, the form of the parasite that resides inside macrophages of the mammalian host, which are non-motile and possess only a residual flagellum; and (2) promastigotes, the extracellular forms that live in the gut of the sandfly vector, which are highly motile and possess a single prominent flagellum. During the developmental transformation of amastigotes to promastigotes, the biosynthesis of α- and β-tubulin proteins is dramatically increased[2], presumably to provide sufficient tubulin for synthesis and maintenance of the flagellum. We show here that the level of α- and β-tubulin mRNA in *Leishmania enrietti* promastigotes is significantly greater than that in amastigotes, as determined by both Northern blot analysis and by *in vitro* translation of cellular RNA. These results show that the regulated expression of the tubulin genes is controlled at the level of mRNA accumulation in *L. enriettii*, by contrast with *Leishmania mexicana*, in which the control of gene expression has been reported to be at the level of translation.

The α- and β-tubulins are the major developmentally regulated gene products during transformation of *Leishmania* amastigotes to promastigotes. The α- and β-tubulin mRNAs are the most abundant messages present in the promastigote stage of the life cycle[3]. Biosynthesis of α- and β-tubulin occurs at a low level in amastigotes but is dramatically increased during their transformation to promastigotes[2]. On the basis of *in vitro* translation experiments, Wallach *et al.*[3] have suggested that control of tubulin biosynthesis may occur at the level of translation. In a recent extension of their work on *L. mexicana*, Fong *et al.*[18] have used heterologous tubulin probes and have found similar levels of tubulin mRNA in promastigotes and amastigotes. In contrast, we find, using homologous cloned copies[4,5] of the α- and β-tubulin genes, significantly more α- and β-tubulin mRNA in promastigotes than in amastigotes of *L. enriettii*.

L. enriettii promastigotes and amastigotes were grown as described in Fig. 1 legend and total nucleic acid extracted. Equal amounts of total nucleic acid from promastigotes and amastigotes were resolved on denaturing agarose gels, transferred to nitrocellulose and probed sequentially with the α- and β-tubulin genomic clones. The filters were re-probed with a cloned ribosomal gene as an internal control. Figure 1 and Table 1 show that the promastigotes contain a minimum of 4–5-fold more α- and β-tubulin mRNA than the amastigotes. Similar results were obtained when the amount of α- and β-tubulin mRNA was measured by *in vitro* translation in the rabbit reticulocyte system (see Table 1). Based on these results, we conclude that the control of α- and β-tubulin synthesis occurs primarily at the level of mRNA accumulation.

The control of tubulin gene expression has been studied in several other systems and has, in general, been found to occur

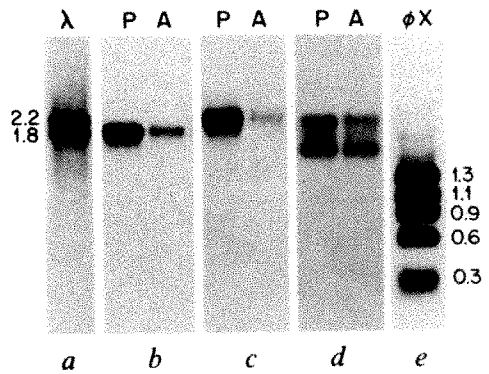

Fig. 1 Estimation of α- and β-tubulin RNA levels in promastigotes and amastigotes by Northern blot analysis. Five micrograms of total nucleic acid isolated by phenol–chloroform extraction from promastigotes (P) or amastigotes (A) of *Leishmania enriettii* were separated on a 1% agarose–formaldehyde gel[12] and blotted onto nitrocellulose. The same filter was sequentially hybridized[4] with nick-translated[15] α-tubulin clone pLTI (ref. 5) (*b*), β-tubulin clone pLEβ3 (S.M.L. and D.F.W., in preparation) (*c*) and with a ribosomal DNA clone (*d*) from *Plasmodium lophurae*[16]. Lane *a* contains *Hin*dIII fragments of λ DNA and lane *e* contains *Hae*III fragments of ΦX174 DNA hybridized to homologous probes. The numbers indicate the size of these molecular weight markers in kilobase pairs. The results in lanes *b* and *c* indicate that the α- and β-tubulin mRNAs in *L. enriettii* are both ~2 kilobases long. In addition, a heavier exposure of the autoradiogram in *c* (not shown) reveals lightly hybridizing bands both above and below the main band.

Methods: Promastigotes were grown to a density of $\sim 2 \times 10^7$ organisms ml^{-1} in Schneider's medium containing 10% heat-inactivated fetal calf serum. Amastigotes were grown by subcutaneous injection of either promastigotes or amastigotes into the noses of male Hartley guinea pigs. Lesions were allowed to develop for about 5 weeks, and parasites were isolated and purified by Percoll gradient centrifugation as described elsewhere[17]. This method yielded viable amastigotes at ~95% purity. RNA was prepared by suspending about 10^{10} parasites in 10 ml of 50 mM HEPES *p*H 7.5, 50 mM KCl, 10 mM EDTA, then lysing the cells with 0.1% Sarkosyl, and immediately extracting three times with 2 vol. phenol–chloroform and once with 2 vol. chloroform.

Table 1 Quantitation of tubulin RNA in promastigotes and amastigotes

	Promastigote/amastigote ratio
α-Tubulin	
Northern blots	
Expt 1	3.5:1
Expt 2	3.9:1
In vitro translation	1.9:1
β-Tubulin	
Northern blots	
Expt 1	5.3:1
Expt 2	4.0:1
In vitro translation	3.7:1

Autoradiograms of the Northern blots in Fig. 1 were quantitated by densitometry. Duplicate lanes were run for each determination, the integrated areas under the peaks were averaged, and these averaged areas were then normalized using the area under the ribosomal RNA peaks. This normalization adjusts for any small differences in the amount of total RNA actually loaded onto promastigote or amastigote lanes. The amount of tubulin RNA measured for the amastigote lane was then arbitrarily assigned a value of 1.0, and the relative amount for promastigotes was calculated. Experiment 1 was performed with RNA isolated by phenol–chloroform extraction (see Fig. 1), while expt 2 was performed with RNA isolated by the guanidinium isothiocyanate procedure[12]. For *in vitro* translation, 2 μg of the RNA samples used in Fig. 1 were translated in the rabbit reticulocyte lysate system[13] (25 μl total volume), and the products were resolved on an 8.5% Laemmli gel[14]. The α- and β-tubulin translation products were quantitated by densitometry of the autoradiogram.

at the level of mRNA accumulation[6-11]. Specifically, flagellar regeneration in *Chlamydomonas rheinhardii* is accompanied by an increase in α- and β-tubulin mRNA levels as determined by *in vitro* translation and Northern blot analysis[6,7]. We find that this is also the case for the α- and β-tubulin genes of *L. enriettii*. This is in contrast to the *L. mexicana* system[3,18] in which similar amounts of tubulin mRNA are reported to be present in the two forms of the parasite. Our results, based both on the direct measurement of mRNA levels by Northern blot analysis using homologous probes and on the *in vitro* translation of mRNA in the rabbit reticulocyte system, clearly indicate that there is several-fold more α- and β-tubulin mRNA in *L. enriettii* promastigotes than in amastigotes. There are two possible explanations for the differences found in the two *Leishmania* systems: either the control of tubulin levels is different in the two species, or the results reflect a difference between the heterologous probes used in the *L. mexicana* experiments[18] and the homologous probes used in our experiments. Thus, the stage-specific regulation of tubulin expression in *L. enriettii* is controlled at the level of mRNA accumulation. Whether this control is exerted through regulation of transcription or through RNA processing or degradation remains to be determined.

Purification, sequencing and synthesis of natriuretic and vasoactive rat atrial peptide

S. A. Atlas*, H. D. Kleinert*, M. J. Camargo†, A. Januszewicz*, J. E. Sealey*, J. H. Laragh*, J. W. Schilling‡, J. A. Lewicki‡, L. K. Johnson‡ & T. Maack†

Mammalian atria contain potent natriuretic and diuretic substances[1,2] which exist in high- and low-molecular-weight forms[2,3] and which appear to be associated with atrium-specific granules[4]. The natriuretic effect of atrial extract is largely accountable for by its renal haemodynamic effects[5-7]; atrial extracts also antagonize hormone- and non-hormone-induced contraction of the isolated rabbit aorta[8-10] and isolated rat kidney vasculature[6]. We have completely purified a low-molecular-weight natriuretic and vasoactive substance from rat atria and characterized it as a 24-amino acid peptide. Synthetic peptide, produced by solid-phase synthesis, mimics biological effects of crude atrial extract and purified peptide; its activity is enhanced by slow oxidation, suggesting a disulphide (Cys 4–Cys 20) configuration for the native peptide. If secreted into blood, this atrial natriuretic peptide ('auriculin B') could be a novel peptide hormone of considerable importance to renal and cardiovascular homeostasis.

Atrial natriuretic factor (ANF) was purified from an acetic acid extract of atria from 1,400 male Wistar rats by gel filtration and reverse-phase HPLC (Fig. 1). Fractions were assayed for natriuretic activity either in the intact rat[1] or in isolated perfused rat kidney[6,11], and for vasorelaxant activity in rabbit thoracic aortic rings[10] contracted with either angiotensin II or histamine. Two broad regions of natriuretic and vasorelaxant activities were found on Sephadex G-50, corresponding to molecular weights of >15,000 and <6,000 (Fig. 1*a*). Application of the low-molecular-weight material to a C_{18} column resulted in a broad active fraction which, upon re-chromatography, was resolved into three peaks of coincident vasorelaxant and natriuretic activity (Fig. 1*b*). One of these was further purified by re-application to the same column (Fig. 1*c*) followed by chromatography on a CN reverse-phase column, which resulted in the association of vasorelaxant activity with a single UV-absorbing peak (Fig. 1*d*).

Table 1 Natriuretic effect of synthetic auriculin in intact rats

Dose (μg per kg)	$\Delta\dot{V}$ (μl min^{-1})	$\Delta U_{Na}\dot{V}$ (μequiv min^{-1})	$\Delta U_K\dot{V}$ (μequiv min^{-1})
1.2 (4)	25.5 ± 9.7	2.5 ± 1.1	1.6 ± 0.2
2.4 (4)	41.3 ± 19.5	6.7 ± 4.1	4.4 ± 1.4
5.0 (4)	52.8 ± 6.5	9.1 ± 1.0	3.7 ± 0.5
7.2 (3)	112.0 ± 12.8	18.3 ± 0.5	3.1 ± 0.8

Synthetic peptide was administered as a bolus injection to rats (average weight 399 g; number of animals in parentheses) anaesthetized with Inactin (100 mg per kg) and maintained on a constant infusion of normal saline (2.2 ml h^{-1}). The change in each parameter was assessed by the difference between the average of three control periods (10 min each) and the first experimental period (maximum response). Data are expressed as the mean ± s.e. $\dot{V}$, urine flow rate; $U_{Na}\dot{V}$, urinary sodium excretion rate; $U_K\dot{V}$, urinary potassium excretion rate. Control values for the 15 animals were: $\dot{V}$, 10.3 ± 2.9 μl min^{-1}; $U_{Na}\dot{V}$, 0.93 ± 0.5 μequiv min^{-1}; and $U_K\dot{V}$, 1.6 ± 0.4 μequiv min^{-1}.

Automated microsequence analysis of the purified substance revealed that it was a 24-amino acid residue peptide rich in glycine, serine and arginine (Fig. 2). This peptide is smaller than the ANFs purified to apparent homogeneity by deBold and Flynn[12] and by Grammer *et al.*[13]. It also differs from the sequences reported recently by Currie *et al.*[14] in that it has an additional arginyl residue at the amino terminus.

Solid-phase synthesis of the peptide shown in Fig. 2 has been accomplished, with a yield of over 150 mg (see Fig. 3 legend for methods). The synthetic peptide had vasorelaxant activity paralleling that of partially purified natriuretic factor (Fig. 3). Its activity was enhanced by allowing it to oxidize slowly, and the activity of the fully oxidized form was very similar to that of the purified peptide (Fig. 3), suggesting the Cys 4–Cys 20 disulphide configuration proposed in Fig. 2.

The synthetic peptide was natriuretic both in the intact rat (Table 1) and in the isolated rat kidney (Table 2). In the latter, perfused in the absence of vasoconstrictors, the peptide increased renal vascular resistance, filtration fraction and glomerular filtration rate (Table 2). In contrast, in the isolated kidney pre-contracted with endogenously generated angiotensin, the peptide decreased vascular resistance (not shown). These effects are similar to those previously described for partially purified peptide, confirming our conclusion that the ANF can have renal vasoconstrictive or vasorelaxant effects

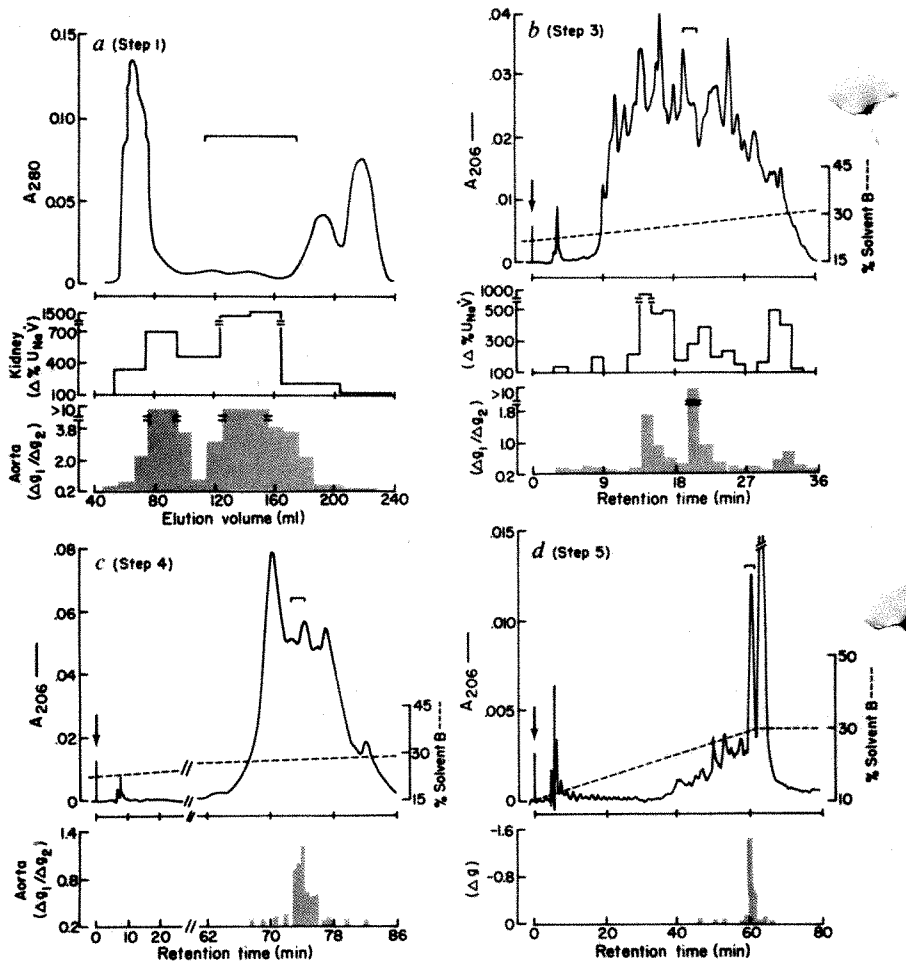

Fig. 1 Purification of natriuretic and vasorelaxant factors from rat atria. Right and left atria from 200 male Wistar rats were homogenized in 8 vols of 1 M acetic acid containing 1 mM phenylmethylsulphonyl fluoride, 3 mM EDTA and 5 μM pepstatin A, centrifuged (10,800*g* for 30 min), and the pellet rehomogenized in 4 vols of buffer. The pooled supernatant was neutralized with ammonium hydroxide[1], centrifuged and lyophilized. *a*, Step 1: gel filtration on a 2.5×45 cm column of Sephadex G-50 (fine) equilibrated with 1 M acetic acid. The extract was reconstituted with 6 ml buffer, centrifuged and applied to the column; flow rate was 0.63 ml min^{-1} and 15.9-min fractions were collected. Aliquots of each fraction were dried (Savant Speed-Vac concentrator), reconstituted in phosphate-buffered saline and assayed for natriuretic activity (0.3 ml) in the intact rat[1] and for vasorelaxant activity (50 μl) in rabbit aortic rings[10]. Rings were first contracted with 2.9×10^{-9}M Ile^5-angiotensin II, then washed, allowed to return to baseline tension and contracted a second time with 1.5×10^{-8}M angiotensin II in the presence of unknown sample; results are expressed as the ratio of the contractile force (Δg tension) generated by the first and second contractions ($\Delta g_1/\Delta g_2$). Six additional extracts were purified similarly and the lyophilized low-molecular-weight region (horizontal bracket) from each was reconstituted with 0.1% aqueous trifluoroacetic acid (TFA), pooled and centrifuged. Step 2 (not shown): one-sixth of the pooled material (representing 1,400 rat hearts), adjusted to 15% acetonitrile (CH_3CN), was applied to a 0.39×30 cm μBondapak C_{18} column, using a Waters U6K injector and solvent delivery system, and eluted at a rate of 0.1 ml min^{-1} with a linear gradient of solvents A (0.1% TFA) to B(CH_3CN) from 85:15 to 45:55 over 40 min. Aliquots of fractions were assayed for natriuresis in the isolated kidney[6,11] and for vasorelaxant activity as described above. A broad region of coincident natriuretic and vasorelaxant activity eluted between 16 and 20 min. The active fractions from six successive runs were pooled and dried overnight. *b*, Step 3; re-chromatography of the step 2 material on the C_{18} column. The sample was reconstituted in solvents A/B 78:22, and chromatographed (in 12 separate applications) at 1.0 ml min^{-1} using a gradient of 22–34% B over 48 min. Aliquots of fractions were tested for natriuretic (100 μl) and vasorelaxant (30 μl) activities as described for step 2. Fractions from each of the three active peaks were pooled and dried overnight. The combined second peak (bracket) from the 12 runs was purified further. *c*, Step 4: re-chromatography of the second peak from step 3. The sample was reconstituted in A/B 77:23, applied to the C_{18} column and eluted at 0.4 ml min^{-1} using a gradient of 23–29% B over 90 min. The bracket indicates fractions with vasorelaxant activity that were pooled from each of six applications. *d*, Step 5: HPLC of the step 4 material on a 0.39×30 cm μBondapak CN column. The solvent system used was A = 0.1% TFA in H_2O and B = 0.055% TFA in CH_3CN. The sample was reconstituted in A/B 90:10, and chromatographed (in three separate applications) at 0.6 ml min^{-1} using a gradient of 10–30% B over 60 min. Vasorelaxant activity was determined by the reduction in tension (Δg) produced in histamine-contracted aortic rings (see Fig. 3 legend for methods). A portion of the active peak (bracket) was re-chromatographed (not shown), giving a single detectable UV peak (retention time 60 min); the remainder was used for sequencing.

depending on the presence of vasoconstrictors[6]. The renal vasoconstrictive effect seems to be exerted preferentially in the efferent arteriole, since it leads to an increase in glomerular filtration rate and in the filtered load of sodium. This latter effect can account for the natriuresis observed in the isolated kidney (Table 2). The vasorelaxant effect predominates in the pre-contracted isolated kidney and possibly in intact animals, leading to an increase in renal blood flow[7,15] and a shift of flow to the inner medulla[15], phenomena known to induce natriuresis. Thus, the available data support the view that the natriuretic effect can be explained by renal haemodynamic actions[6]. Whether this peptide has, in addition, a direct tubular action remains to be demonstrated.

The synthetic peptide, like partially purified preparations, also has potent relaxant effects on the rabbit aorta pre-contracted with histamine (Fig. 3), noradrenaline[8–10], angiotensin II[10] and K^+-depolarization[10] (not shown). No vasoconstrictive effect was detected in aortic rings. The ability to antagonize vasoconstrictors might explain the lowering of blood pressure by atrial extracts[1]. Although no consistent effect on blood pressure was observed in assay rats, preliminary studies in anaesthetized dogs show that constant infusion of the synthetic peptide (at 0.1 μg per kg per min) causes a 10–15% fall in mean arterial pressure.

We have reported here the first synthesis of a natriuretic and vasoactive factor present in mammalian atria. It would be premature to conclude that the structure proposed (Fig. 2) represents the complete sequence of the naturally occurring peptide. The large-molecular-weight active substance in atrial extracts

Table 2 Effects of synthetic auriculin on renal function in isolated perfused rat kidney

	Control	Experimental
GFR (ml min^{-1})	0.43±0.05	0.63±0.03*
FF	0.014±0.002	0.021±0.001*
RVR (mm Hg ml^{-1} min)	2.9±0.1	3.9±0.3*
$\dot{V}$ (μl min^{-1})	19.8±4.8	97.6±19.4*
FL_{Na} (μequiv min^{-1})	60.2±7.9	90.1±5.2*
T_{Na} (μequiv min^{-1})	60.0±7.6	84.2±4.8*
$U_{Na}\dot{V}$ (μequiv min^{-1})	0.66±0.35	6.01±1.99*
FE_{Na} (%)	0.97±0.38	6.6±2.0*
$U_K\dot{V}$ (μequiv min^{-1})	0.44±0.19	1.46±0.16*
FE_K (%)	19.8±5.9	52.1±6.2*

Functioning isolated rat kidneys were perfused in a closed-circuit system with 60 ml of oxygenated perfusate (Krebs–Henseleit bicarbonate buffer, 7.5 g per dl albumin, glucose and amino acids) at an effective perfusion pressure of 90–100 mm Hg (refs 6, 11). After control clearance periods, 150 ng of synthetic peptide were added to the perfusate. Effects on each parameter were noted immediately and reached a maximum during the third 10-min clearance period; these peak values are given as the experimental data. GFR, glomerular filtration rate; FF, filtration fraction; RVR, renal vascular resistance; $\dot{V}$, urine flow rate; FL_{Na}, filtered load of sodium; T_{Na}, tubular reabsorption of sodium; $U_{Na}\dot{V}$, urinary sodium excretion rate; FE_{Na}, fractional sodium excretion; $U_K\dot{V}$, urinary potassium excretion rate; FE_K, fractional potassium excretion. Results are the mean ±s.e. of four kidneys.

*$P<0.05$ compared with control (Student's *t*-test).

Fig. 2 Amino acid sequence of pure auriculin A. The sequence was determined from 1 nmol of pure protein (step 5, Fig. 1*d*) using the Applied Biosystems 470A gas-phase sequencer. Phenylthiohydrazine amino acids were identified with a Beckman 335T HPLC, using a 0.46×25 cm IBM CN column and a gradient slightly modified from that of Hunkapiller and Hood[17]. The effect of slow oxidation on the biological activity of the synthetic peptide (see text and Fig. 3 legend) suggests the Cys 4–Cyc 20 disulphide configuration shown.

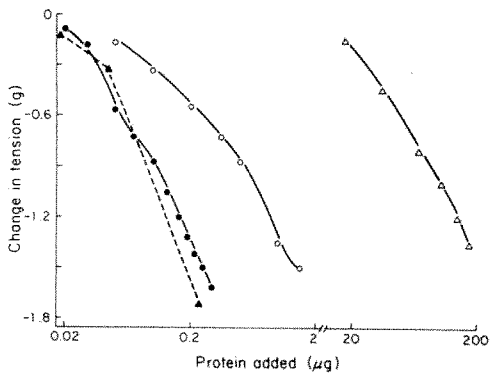

Fig. 3 Comparison of the vasorelaxant activity of purified and synthetic auriculin A on histamine-contracted rabbit thoracic aortic rings. Solid-phase synthesis of the peptide shown in Fig. 2 was performed on a Biosearch SAM II automated peptide synthesizer using t-BOC amino acids. Following repetitive deblocking cycles with TFA, subsequent couplings of amino acids were achieved with a water-soluble carbodiimide. After removal from the polystyrene resin with liquid HF, the synthetic peptide was reduced, purified and slowly re-oxidized[19]. Peptide was dissolved in 2 M acetic acid containing 10 mM β-mercaptoethanol and applied to a 2×96 cm column of Sephadex G-25 (fine) equilibrated with the same buffer (flow rate 0.335 ml min^{-1}, 14.9-min fractions). The major UV (250 nm)-absorbing peak (elution volume 172.5 ml) was lyophilized, resuspended in 0.05 M ammonium acetate, *p*H 7.2 (at 50 μg peptide per ml), allowed to slowly re-oxidize by exposure to air at 4°C in the dark for 60 h and again lyophilized. This material was compared with partially purified (step 1) and purified (step 5) ANF in its ability to relax histamine-contracted aortic rings. Rings were suspended in 10 ml aerated Kreb's buffer under 1.5 g passive tension, pre-contracted with 6×10^{-6} M noradrenaline, washed and allowed to return to baseline tension, as described[10]. A sustained contraction was induced with 5 μM histamine; increasing amounts of purified or synthetic peptide were then added in cumulative fashion. Change in tension is related to the cumulative amount of protein added. Protein concentration was determined by the method of Lowry *et al.*[18] (for step 1) or by dry weight. Purified peptide: Δ, step 1; ▲, step 5. Synthetic peptide: ○, before oxidation; ●, after oxidation.

might represent a precursor, and several low-molecular-weight forms with similar biological activities have been identified[12–14] (see also Fig. 1). We have also detected a form comprising the peptide described here plus an additional C-terminal tyrosine ('auriculin B', unpublished data). Multiple peptides might arise through intracellular processing or as artefacts formed during purification. Our peptides could be fragments of the larger ones purified earlier[12,13]; except for the presence of only a single cysteine in one report[12], the available amino acid composition data are consistent with this possibility. In any event, the present studies demonstrate unequivocally that both the natriuretic and the haemodynamic effects induced by atrial extracts can be accounted for by a single peptide or class of peptides.

An interesting feature of auriculin A is that its C-terminal dipeptide is identical to that of bradykinin. If this C-terminus (rather than Phe-Arg-Tyr) occurs *in vivo*, the peptide might be a substrate for angiotensin-converting enzyme (kininase II), the dipeptidyl hydrolase responsible for the formation of angiotensin II and inactivation of kinins. If so, the secreted peptide might be activated, inactivated or altered in its biological activities on passage through the lung, kidney or other tissues rich in converting enzyme. Although there is so far no proof that this substance is released into the circulation, its reported association with specific membrane-bound atrial granules[4,16] makes it likely. Its potent natriuretic and vascular actions suggest a possible major role in fluid volume and blood pressure haemostasis.

Note added in proof: After submitting this report we learned of two earlier papers describing 28-residue rat[20] and human[21] atrial peptides with three additional N-terminal amino acids and the C-terminal Tyr found in auriculin B. Although the ANF precursor sequence (see following papers) predicts the auriculin B as a likely product of proteolytic processing, further work is required to clarify this point.

We thank Dr D. Hudson of Biosearch Inc. for advice concerning peptide synthesis and Ms E. Eich, R. M. Aceto, R.-J. Chang, D. Marion and G. Odell for technical assistance.

Atrial extracts contain factors which induce potent natriuresis[1,2] changes in renal haemodynamics[3], and relax pre-contracted vascular smooth muscle[3–5]. Low-molecular-weight peptides which mimic these actions have now been purified by several groups[1,2,6–12], including ours (see accompanying paper[9]), and higher-molecular-weight proteins with similar but less potent biological activities have also been identified and are presumed to be precursors[6,7,9–12]. If released into the circulation, these peptides, collectively called atrial natriuretic factor (ANF), may play a significant part in blood-pressure homeostasis, regulation of extracellular fluid volume and as antagonists to the hypertensive effects of the renin–angiotensin system and other hormonal and neurotransmitter systems. We describe here the isolation and characterization of rat atrial cDNA clones which encode ANF. Nucleotide sequence analysis shows that auriculin[9] corresponds to the 25 amino acids located close to the C-terminus of a 152-amino acid ANF precursor. Analysis of the *in vitro* translation products of precursor ANF mRNA suggests that multiple forms of the precursor may exist.

Fig. 1 Synthesis and use of oligonucleotide probes. The sequence of amino acids 4–12 of rat auriculin[9] is shown along with the sequence of the four oligonucleotide mixtures, a and b for region 1, and c and d for region 2. R = A or G, Y = T or C, N = A, G, T or C. Each oligonucleotide mixture was synthesized on a Biosearch SAM I oligonucleotide synthesizer by a modification of the standard phosphotriester method using mesitylenesulphonyl chloride in the presence of *N*-methylimidazole as condensing reagents[28,29] and purified by polyacrylamide gel electrophoresis. Double-stranded cDNA was synthesized from rat atrial poly(A)$^+$ RNA. After the sequential addition of *Eco*RI and *Sal*I oligonucleotide linkers[13] the cDNA was ligated to the plasmid expression vector pUC9 (ref. 14) and transformed onto *Escherichia coli* MC1061 (ref. 30). 5 μg of rat atrial poly(A)$^+$ RNA yielded about 25 ng of cDNA, size-selected to greater than 300 base pairs (bp), and gave a library of about 200,000 independent recombinants. These were plated on Millipore Triton-free nitrocellulose filters, replica-plated and the library was stored frozen on glycerol-impregnated filters at −70 °C (refs 18, 19). Replica filters of the library were processed for hybridization[15–17]. After baking, the filters were washed overnight at 68 °C with shaking in a large volume of 3 × SSC (20 × SSC = 3 M NaCl, 0.3 M sodium citrate *p*H 7.5), 0.1% SDS and then prehybridized in 6 × SSC, 0.1% SDS, 1 mM EDTA, 5 × Denhardt's solution[31], 0.05% sodium pyrophosphate at 50 °C for at least 2 h (ref. 16). The filters were then hybridized with 2.5×10^6 c.p.m. (1 pmol ml^{-1}) ^{32}P-labelled oligonucleotide mixture per filter, in hybridization solution containing 100 μg ml^{-1} tRNA at 45 °C for 1 h in a shaking water bath. The thermostat was then lowered to 25 °C and the bath allowed to equilibrate overnight. The filters were washed twice in 6 × SSC, 0.1% SDS at room temperature for 15 min, then washed at 35 °C (for probes c and d) or 39 °C (for probes a and b) for 1–2 min. The final washing temperature was obtained from the empirical formula of Suggs *et al.*[32], $T_d = 4(G+C) + 2(A+T)$. The filters were then dried and autoradiographed with intensifying screens.

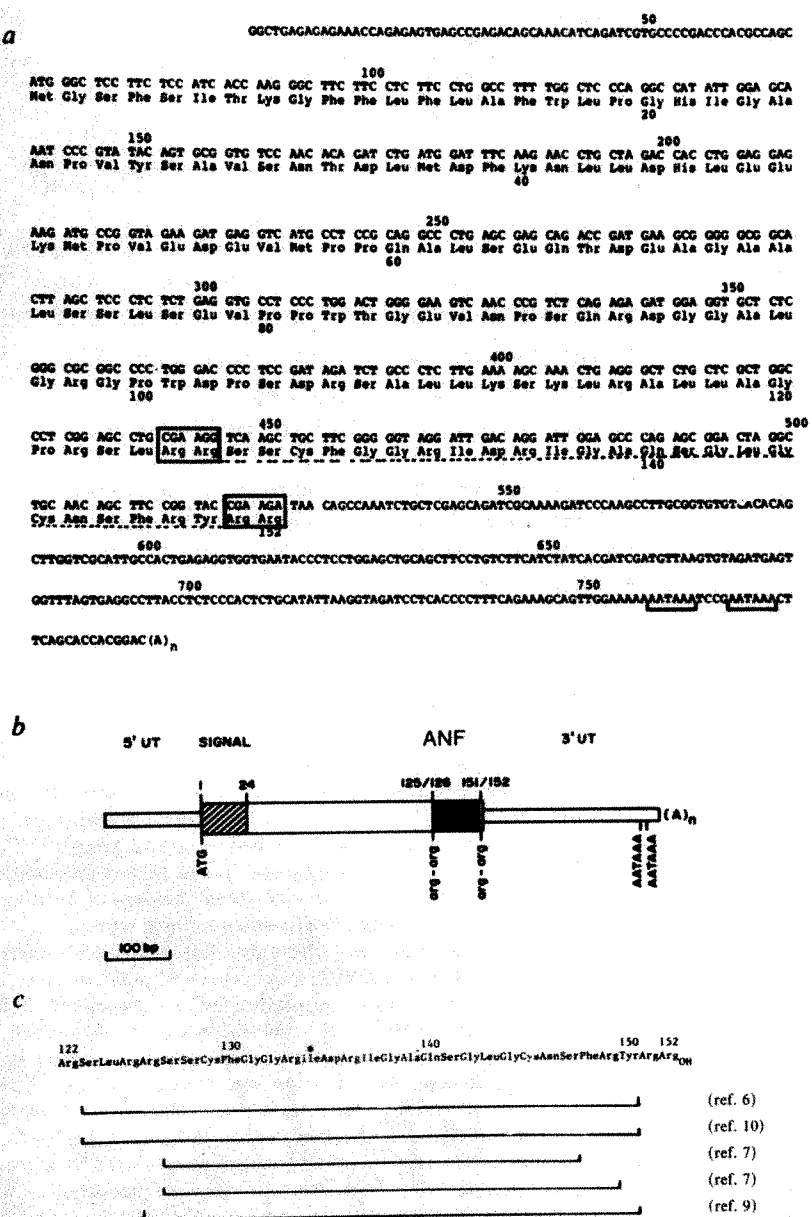

Fig. 2 *a*, Nucleotide sequence of precursor ANF. The nucleotide sequence was established by the chain-termination method[33] using cDNA fragments subcloned into the M13 vectors mp8 and mp9 (ref. 34). All sequences were determined on both strands with the exceptions of nucleotides 755–790. The sequence for this region was obtained from another cDNA clone isolated using pNF1 as a hybridization probe. The basic Arg-Arg dipeptides, which are implicated in the processing of precursor ANF, are boxed, while the two AATAAA sequences involved in polyadenylation are underlined. *b*, Schematic representation of the structure of precursor ANF. The precursor sequence, amino acids 1–152, is shown with the putative signal peptide marked by cross-hatching and the auriculin sequence marked by stippling. The positions of the two Arg-Arg dipeptides (amino acids 125–126 and 151–152), which are potential processing sites, are shown. The 5′- and 3′-untranslated regions (UT) are marked and the two putative polyadenylation signals, AATAAA, are identified. *c*, Amino acid sequences of rat and human atrial peptides. The sequences of other biologically active peptides[6,7,9,10] are shown. The Ile at position 134 (marked with an asterisk) is a Met in the human sequence[10].

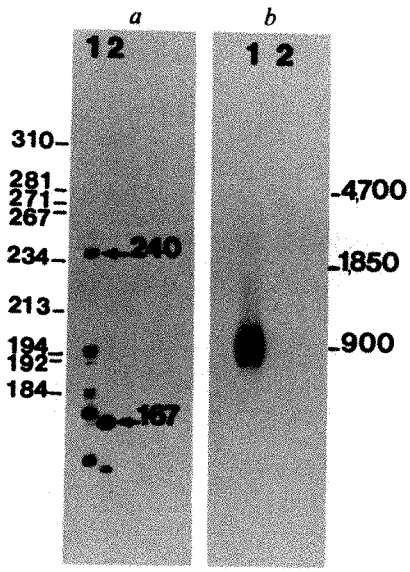

Fig. 3 Size determination of precursor ANF mRNA. *a*, Primer extension. Five μg pNF1 DNA were digested with *Bgl*II, treated with bacterial alkaline phosphatase and 5'-end-labelled with [γ-^{32}P]ATP by polynucleotide kinase. The kinase was heat-inactivated, the DNA digested with *Dde*I and the 167-bp *Dde*I–*Bgl*II fragment (nucleotides 3–170), ^{32}P-labelled at the *Bgl*II end only, was recovered from a polyacrylamide gel. One-fifth of the eluted DNA fragment was co-precipitated with 1 μg rat atrial poly(A)$^+$ RNA[35,36], resuspended in 40 μl 80% formamide, 0.4 M NaCl, 40 mM PIPES *p*H 6.4, 1 mM EDTA (refs 37, 38), heated to 68 °C for 10 min and hybridized at 55 °C for 3 h. Following ethanol precipitation the annealed primer–template complex was incubated with unlabelled deoxynucleoside triphosphates and reverse transcriptase and the size of the primer extension products estimated by electrophoresis on a 5% acrylamide, 7 M urea gel. Lane 1, primer-extension products; lane 2, unextended primer fragment. Sizes of markers fragments are given in base pairs. The full-length primer extension product (240 nucleotides) is 73 nucleotides longer than the primer fragment. Since the *Dde*I priming site is 3 nucleotides from the end of pNF1, the cDNA clone is about 70 nucleotides short of being full length. A strong intermediate band of about 195 nucleotides is also seen and may represent a region of secondary structure in the mRNA. *b*, Northern blot analysis. Poly(A)$^+$ RNA (2 μg) isolated from rat atrium, or rat ventricle, was fractionated by electrophoresis on a 1.4% agarose gel containing methyl mercuric hydroxide[39]. The RNA was transferred to a nitrocellulose filter[40] and probed with nick-translated pNF1 DNA. Lane 1, atrial poly(A)$^+$ RNA; lane 2, ventricular poly(A)$^+$ RNA. The positions of 28S and 18S rRNA markers are given in bases.

The sequences of atrial natriuretic peptides reported to date differ slightly in length at both the N- and C-termini, which may be a reflection of variable proteolytic processing of a precursor. We used these amino acid sequences to design oligonucleotide probes to screen a rat atrial cDNA library cloned in the vector pUC9 (refs 13, 14) (Fig. 1). These probes were synthesized to correspond to two non-overlapping regions of the peptide (Fig. 1). Due to the degeneracy of the codons, we chose to synthesize two oligonucleotide pools for each region. Thus, region 1 was covered by two tetradecamer oligonucleotide pools, a and b, each consisting of 64 sequences, while region 2 was covered by another two tetradecamer pools, c and d, each consisting of 72 sequences.

The pools of oligonucleotides were used to screen the atrial cDNA library by colony hybridization[15–17]. Four replica filters were prepared from each master filter[18,19], and each replica was probed with one of the oligonucleotide pools. A colony was considered positive if it hybridized with one of the region 1 and one of the region 2 probes. One clone was picked as the most likely candidate for encoding auriculin as it not only hybridized very strongly to the oligonucleotide probes, but also represented an atrium-specific sequence. This was demonstrated by its hybridization to a random primed atrial, but not ventricular, cDNA probe.

Nucleotide sequence analysis confirmed that this clone (pNF1) encodes an auriculin precursor. When the atrial cDNA library was re-screened with this cDNA insert, approximately 0.5% of the colonies hybridized, showing that ANF is a major species in rat atrial mRNA. The complete nucleotide sequence and structure of the precursor is shown in Fig. 2. A single open reading frame encoding a 152 amino acid sequence extends from an ATG initiation codon at nucleotide 69 to a TAA termination codon at nucleotide 525. Within this reading frame the sequence of the various forms of biologically active atrial natriuretic peptides can be identified (Fig. 2*c*). The sequence in Fig. 2*a* has a 5'-untranslated region of 68 nucleotides and a 3'-untranslated region of 266 nucleotides. Two potential polyadenylation signals, AATAAA (ref. 20), are seen in the 3'-untranslated region. Multiple polyadenylation sites have also been observed in other genes[21,22].

To confirm that the cDNA clone, pNF1, represents an essentially full-length transcript of precursor ANF mRNA, we isolated a restriction enzyme fragment from pNF1 and used it to prime cDNA synthesis from atrial poly(A)$^+$ RNA. The results (Fig. 3*a*) show that pNF1 is about 70 nucleotides short of a full-length cDNA clone. The mRNA for precursor ANF is therefore about 850 nucleotides long (excluding the poly (A) tail). This conclusion is supported by the results of a Northern blot (Fig. 3*b*), in which pNF1 hybridizes to an atrial mRNA of approximately 900 nucleotides but is not detected with ventricular mRNA (Fig. 3*b*).

Other evidence supports our identification of the reading frame of the ANF precursor. The precursor has been proposed to be a secretory protein, found in atrial granules, and would therefore be expected to have a signal peptide, and indeed, the sequence following the proposed initiation codon (Fig. 2*a*) encodes a stretch of amino acids, starting at position 9 which, though unusually rich in phenylalanine, has the hydrophobic character of a signal peptide[23]. Cleavage of this sequence could occur after either the glycine at position 23 or the alanine at position 24 (the preferred amino acids at the signal peptide cleavage site), producing a signal peptide of normal length. Eukaryotic genes do not have a ribosome-binding site sequence like that seen in prokaryotes, although a consensus sequence, CC$\frac{A}{G}$CCATGG, is found around the initiation codon[24]. In the case of precursor ANF, this sequence is CCAGCATGG. Finally, the identification of the reading frame is supported by the fact that the cDNA clone is similar in size to the mRNA, and that the molecular weight of the precursor protein as predicted from the sequence matches closely with the observed size (see below). A schematic version of precursor ANF is shown in Fig. 2*b*.

The diversity of previously identified amino acid sequences encoding natriuretic peptides (see Fig. 2*c*) does not allow precise determination of the sites at which precursor ANF is processed. However, the sequence of auriculin is flanked on both sides by basic dipeptides (Arg-Arg at positions 125–126 and 151–152) which have been identified in other hormone precursors as proteolytic processing sites[25]. The varying lengths of the active peptides identified by the different groups could result either from the precursor being processed at sites other than Arg–Arg or from an artefactual proteolytic cleavage of the precursor during purification. The Arg-Arg dipeptide at the C terminus of auriculin is immediately followed by the TAA termination codon and, as such, is similar to that of the corticotropin-releasing factor precursor[26].

The predicted molecular weight (MW) of precursor ANF is 16,720. To determine the actual precursor size, atrial mRNA encoding precursor ANF was purified by hybrid selection[27], using pNF1 DNA, and translated *in vitro*. The selected translation products were then analysed by two-dimensional gel electrophoresis and compared with the total translation products from atrial and ventricular mRNA (Fig. 4). Translation of the

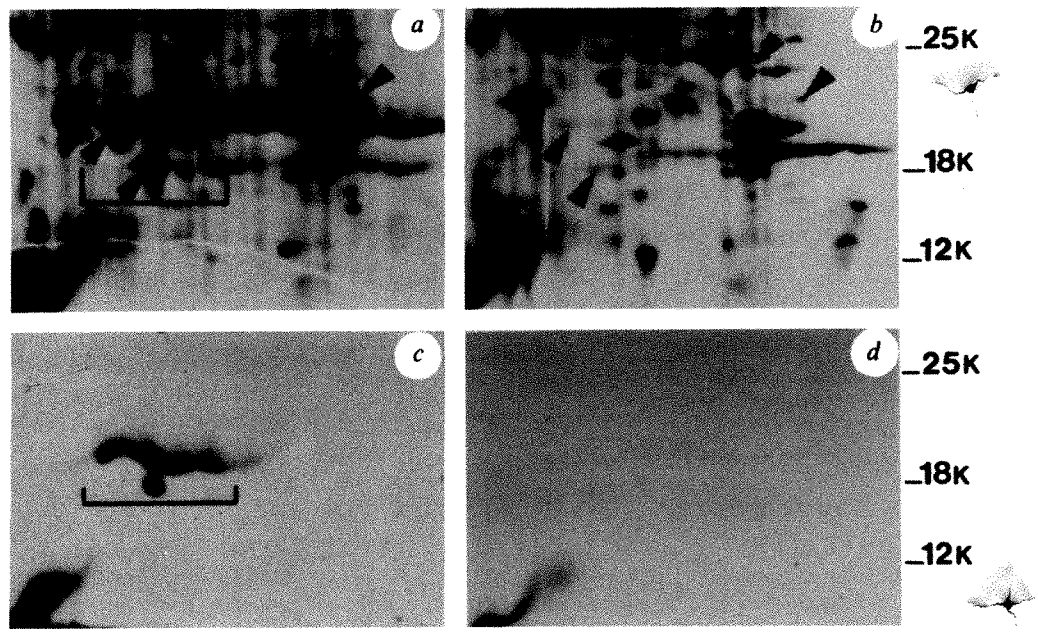

Fig. 4 Two-dimensional gel fractionation of cell-free translation products encoded by poly(A)$^+$ RNA isolated from: *a*, rat atria; *b*, ventricle, or selected by hybridization[27] of atrial (*c*) or ventricular (*d*) poly(A)$^+$ RNA to pNF1 DNA. 5 μg of plasmid pNF1 DNA were immobilized on 1-cm^2 nitrocellulose disks and hybridized with 5 μg of poly(A)$^+$ RNA for 3 h at 50 °C in 20 mM PIPES, *p*H 6.4, 1 mM EDTA, 65% formamide, 5 × SSC, 0.1% SDS. Filters were then washed extensively in 10 mM Tris-Cl *p*H 7.5, 0.15 M NaCl, 1 mM EDTA, 0.1% SDS at 70 °C and at 37 °C in the same buffer without SDS. Hybridized RNA was eluted in H_2O at 100 °C in the presence of 50 μg tRNA for 1 min, quick-frozen at −70 °C, thawed and precipitated by the addition of 2 vols absolute ethanol. Hybrid-selected RNA and total poly(A)$^+$ RNA was translated using a commercially available rabbit reticulocyte lysate system in the presence of 250 μCi ml^{-1} ^{35}S-methionine. Acid-precipitable radioactivity (1×10^6 c.p.m.) translated from total atrial and ventricular poly(A)$^+$ RNA or 1×10^5 and 5×10^4 c.p.m. of acid-precipitable radioactivity translated from hybrid-selected atrial and ventricular RNA, respectively, was fractionated by two-dimensional gel electrophoresis. The first dimension consisted of isoelectric focusing using a *p*H 3.5–10 gradient[41] while the second dimension was a 15% acrylamide–SDS gel[42]. The gels were equilibrated in 1 M sodium salicylate, dried and fluorographed at −70 °C for 24 h. The electrophoretic positions of several atrium-specific translation products in the 12,000–30,000 MW range are marked by arrows. The translation products encoded by pNF1-hybrid-selected atrial RNA are indicated by brackets.

hybrid-selected RNA yielded at least three proteins with molecular weights of 16,500–18,500 (Fig. 4*c*). These translation products selected by pNF1 represent abundant atrial species which are not present in the ventricle.

The function of the N-terminal portion of the precursor is not clear. Higher-molecular-weight forms of biologically active material have been isolated[4,7,9–11] but they have less potent natriuretic and diuretic effects than auriculin. These activities could result from the proteolytic cleavage of the precursor in the assay system releasing auriculin. The N-terminal fragment lacking auriculin has not been identified *in vivo*, and therefore has no biological activity ascribed to it. Knowledge of the sequence of the entire precursor will allow us to express the complete ANF precursor, or defined fragments of it, in yeast or bacteria, and to investigate their biological activities.

Note added in proof: We have sequenced the primer extension product and confirmed the sequence from nucleotides 7 to 54. Nucleotides 1–6 are, however, incorrect, and probably result from a cloning artefact.

We thank Eliza Pond for preparation of the manuscript, Derek Woods for advice on oligonucleotide screening and our colleagues at CBI for their encouragement and advice.

Structure of rat atrial natriuretic factor precursor deduced from cDNA sequence

Masatoshi Maki, Ryoichi Takayanagi, Kunio S. Misono, Kailash N. Pandey, Clark Tibbetts* & Tadashi Inagami

Departments of Biochemistry and *Microbiology, Vanderbilt University School of Medicine, Nashville, Tennessee 37232, USA

The atrium of the heart contains peptides, termed atrial natriuretic factors (ANFs), diuretic[1] and smooth-muscle-relaxing[2–4] activities. In view of its potent effects on salt metabolism in the kidney and on vascular smooth muscle, ANF is considered to play an important part in the control of fluid volume and vascular function. Several different ANF peptides varying in size have been isolated[3–10] and their amino acid sequences determined[4,6–10]. Analysis of the

sequences of the peptides suggests that they are derived by proteolysis from the same precursor. To examine this hypothesis, we have cloned cDNAs of the ANF precursor using rat atrial mRNA, determined its nucleotide sequence and deduced its amino acid sequence. The ANF precursor consists of 152 amino acid residues including a putative signal peptide sequence. This sequence contains the amino acid sequences of all the ANF peptides reported to date[4,6–10].

For use as hybridization probes, two pentapeptide segments of rat ANF peptide[4] which gave the least numbers of possible combinations of codons were chosen for constructing 14-mer mixed oligonucleotides designated oligo I and oligo II (Fig. 1*a*). The ability of the synthetic oligonucleotides to specifically hybridize with mRNA for ANF was tested, using oligo I as a primer, by reverse transcription of poly(A) RNA isolated from rat atrium (Fig. 1*b*). Poly(A) RNA from ventricle was used as a control. Following urea-polyacrylamide gel electrophoresis, only one major cDNA band corresponding to 460 nucleotides in length was produced from atrial mRNA, but not from ventricular mRNA, suggesting specific hybridization of oligo I to ANF mRNA.

A library of rat atrial cDNA clones was constructed using the cloning vector of Okayama and Berg[11] (see Fig. 2 legend for experimental details). By screening with oligo I, 56 hybridization-positive clones were selected from 900 transformants. Using oligo II as the second probe, candidates were narrowed down to eight clones. All eight clones had cDNA inserts of indistinguishable sizes with common restriction endonuclease sites for *Pst*I, *Xho*I, *Hin*cII and *Bgl*II.

The nucleotide sequence analysis of one of these clones, pOB8, by the method of Sanger *et al.*[12–14] revealed that it lacks a 5′-noncoding sequence as well as the ATG initiation triplet.

A clone with a longer cDNA insert, pGH33, was isolated from a second atrial cDNA library prepared by the method of Gubler and Hoffman[15] (see Fig. 2 legend). Its nucleotide sequence, determined by the methods of Sanger *et al.*[12–14] and of Maxam and Gilbert[16], was in agreement with that of pOB8 in the overlapping region. The complete nucleotide sequence of the ANF cDNA clones consisting of 786 residues is presented in Fig. 3.

The nucleotide sequence from residue 376 to residue 450 corresponds exactly to the previously determined amino acid sequence of ANF peptide (the boxed region in Fig. 3); it allowed us to define the reading frame for the entire ANF precursor and, thus, deduce its amino acid sequence. The distance from the 5′ end to the position of oligo I was 461 nucleotides long, which agrees with the observed size (460 nucleotides) of the major cDNA product of the primer-extended reverse transcript of atrial mRNA (Fig. 1*b*). Therefore, the first ATG triplet (nucleotide residues 1–3) proximal to the 5′ end of the sense strand was designated as the initiation codon. An unusually

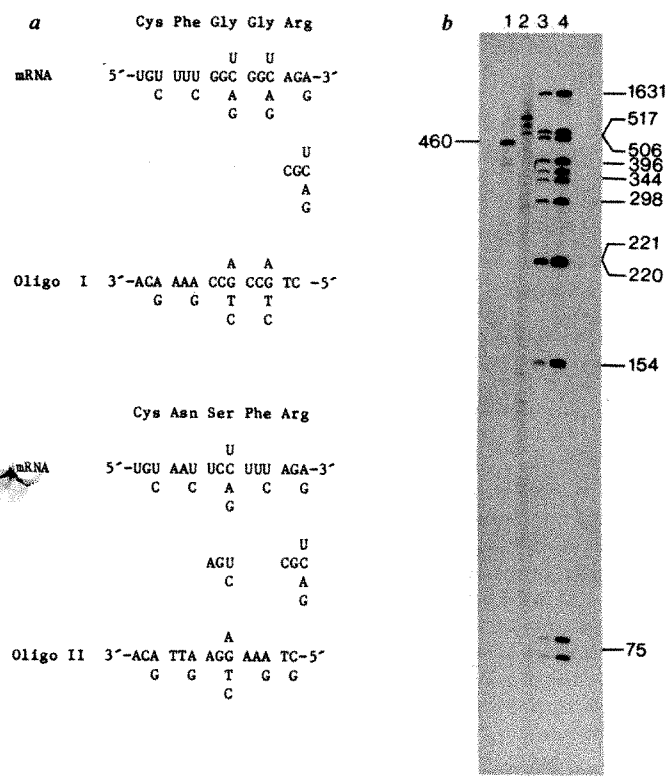

Fig. 1 *a*, Synthetic oligonucleotides used for screening cDNA clones for rat ANF. Mixed 14-mer oligodeoxynucleotides, oligo I and oligo II (custom-synthesized by American Bionuclear) are complementary to all possible coding sequences corresponding to the two pentapeptide sequences which had been found in ANF peptides[4]. Codons for Arg in oligo I and for Ser in oligo II were selected on the basis of the frequency of codon usage in rat mRNA. *b*, Electrophoretic analysis of cDNA products synthesized from poly(A) RNA using oligo I as a primer. Poly(A) RNA was isolated from atria and ventricles of Sprague–Dawley rats by the guanidine isothiocyanate–CsCl procedure[22] followed by oligo(dT)-cellulose chromatography. cDNA was synthesized from 20 μg of poly(A) RNA obtained from atria (lane 1) or ventricles (lane 2), using ^{32}P-labelled oligo I (0.125 μg, 1.5×10^8 c.p.m. μg^{-1}) as a primer for reverse transcriptase reaction, and was electrophoresed on an 8% polyacrylamide gel containing 7 M urea[23]. *Hin*fI digests of pBR322 (NEN) were labelled with ^{32}P and used as markers for the sizes and radioactivity of synthesized cDNAs (lane 3, 1,200 c.p.m.; lane 4, 6,000 c.p.m.).

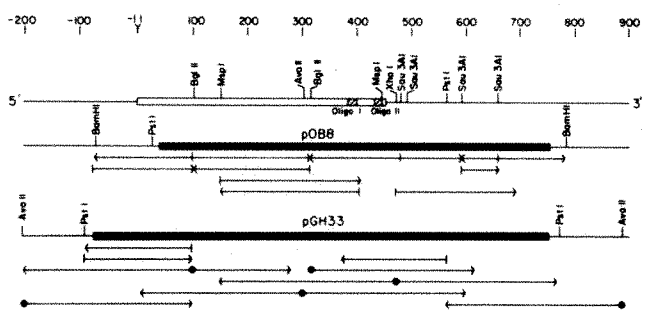

Fig. 2 Sequencing strategy of ANF cDNA. Clones pOB8 and pGH33 were isolated from two cDNA libraries prepared independently by the procedures of Okayama and Berg[11,24] (method A) and Gubler and Hoffman[15] (method B) respectively.

Methods: A: cDNA–plasmid recombinant molecules were prepared using 4 μg of poly(A) RNA from rat atria, 2.2 μg of dT-tailed pcD vector[11] and dG-tailed linker. *Escherichia coli* N-38, a substrain of HB101, was used for transformation and ampicillin-resistant transformants were screened by colony hybridization[25] at 37 °C or 41 °C with oligo I (Fig. 1*a*) labelled with ^{32}P at the 5′ end. The hybridization-positive clones were re-screened with oligo II (Fig. 1*a*) at a hybridization temperature of 31 °C or 37 °C. B: The first cDNA strand was synthesized using 10 μg of poly(A) RNA as template which had been denatured by 10 mM of methylmercuric hydroxide[26]. The RNA was replaced by the second cDNA strand using a mixture of RNase H, DNA polymerase I and DNA ligase. The double-stranded cDNA thus obtained was tailed with dCTP, annealed to *Pst*I-cleaved and dG-tailed pBR322 and introduced into *E. coli* N-38. Tetracycline-resistant transformants were screened by colony hybridization with ^{32}P-labelled *Msp*I fragment of pOB8 cDNA as a probe. The nucleotide sequences of the plasmid inserts pOB8 and pGH33 (solid boxes) were determined both by the dideoxy terminator method of Sanger *et al.*[12] (sequencing direction indicated by arrows with a short vertical line) and by the method of Maxam and Gilbert[16] (indicated by arrows with solid circles). In the former, restriction fragments were subcloned into M13mp8 or M13mp9 (ref. 13) and Klenow fragment of DNA polymerase I or reverse transcriptase (ref. 14) was used in the chain-termination reaction. The open box indicates the coding region flanked by an initiation codon and a termination codon. The hatched regions represent the segments corresponding to synthetic oligonucleotides (oligo I and oligo II) used as probes.

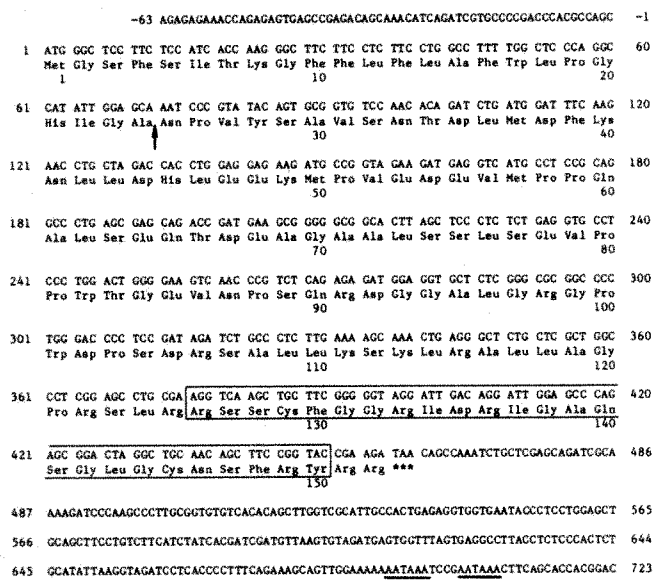

Fig. 3 Nucleotide sequence of rat ANF cDNA. Nucleotides are numbered in the 5′ and 3′ direction beginning with the first residue of the ATG triplet encoding the translational initiation methionine, and the nucleotides on the 5′ side of residue 1 are indicated by negative numbers. The deduced amino acid sequence is shown below the nucleotide sequence. A potential cleavage site for the signal peptide is indicated by an arrow between residues 24 and 25. Potential poly(A) addition signals (AATAAA)[27] are underlined. The boxed region shows the amino acid sequence previously determined by automated Edman degradation of the 25-amino acid ANF peptide[4].

long inverted repeat sequence (nucleotides 467–482) lies immediately downstream from the TAA stop codon.

The nucleotide sequence of rat ANF cDNA reveals that the ultimate precursor of ANF peptide comprises 152 amino acids with a calculated molecular weight of 16,556. The amino-terminal 24-amino acid sequence appears to be a signal peptide[17] as it contains a region which is rich in hydrophobic amino acids with bulky side chains (positions 10–18) and is followed by a region containing amino acids having small side chains[18]. While this work was in progress, Thibault *et al.*[19] reported the amino-terminal sequence of a rat high-molecular-weight ANF, which corresponds with the stretch from Glu 78 to Asp 135 in the precursor sequence deduced in the present study.

The finding of the carboxy-terminal sequence -Arg-Arg (151–152) is intriguing as no active ANF peptide isolated and sequenced to date contains this structure[4,6–9]. The possibility cannot be excluded that the cleavage of this pair of arginine residues may be related to the activation of ANF.

The recent findings linking atrial deficiency of natriuretic activity with hereditary congestive heart failure in a strain of Syrian hamster[20] and with spontaneous hypertension in rat[21] strongly indicate that ANF has an important role in cardiovascular regulation. cDNA for ANF obtained in the present study may be useful in elucidating regulation of ANF mRNA synthesis and its involvement in pathogenesis of such cardiovascular diseases. The deduced amino acid sequence of the precursor of ANF should also facilitate elucidation of the mechanism of synthesis, processing and secretion of ANF.

We thank Dr H. Okayama for his gift of a pcD vector and dG-tailed linker, Cynthia Hager for DNA sequencing and William Burkhart for technical assistance. This work was supported by NIH grants HL-14192 and HL-22288, grant-in-aid 84-1291 from the American Heart Association and an Investigatorship award from the American Heart Association Tennessee Affiliate.

Recent identification of natriuretic–diuretic activity in peptides isolated from human[1] and rat [2–5] atrial tissue implicates them in the control of extracellular fluid volume and electrolytic homeostasis. The presence of multiple forms of the peptides ranging from 3,000 to 13,000 molecular weight (MW) suggests they may all derive from the same precursor[1–6]. The established amino acid sequence of α-human atrial natriuretic polypeptide (α-hANP)[1], a 28-residue peptide with potent natriuretic activity, provided the means to elucidate the structure of the precursor for α-hANP and the gene encoding it. Here we report the cloning and sequence analysis of the cDNA of human atrial mRNA encoding a precursor of α-hANP. The cDNA encodes γ-human atrial natriuretic polypeptide (γ-hANP) of 13,000 MW, whose C-terminal 28 amino acid residues may be processed as α-hANP.

A library of cDNA clones from human atrial poly(A)$^+$ RNA was constructed using the method of Okayama and Berg[7]. To probe cloned cDNA for the precursor of α-hANP, tetradecamer oligodeoxyribonucleotides representing all possible complementary sequences corresponding to amino acids 12–16, Met-Asp-Arg-Ile-Gly, of α-hANP (excluding the third nucleotide residue of the glycine codon) were synthesized by modified triester methods[8] as two pools (oligo I and oligo II). The cDNA library was screened by hybridization with ^{32}P-labelled probes. Twenty-three clones, which hybridized with oligo II but not with oligo I, were isolated from about 40,000 transformants. Plasmids isolated from eight of these clones were submitted to nucleotide sequence analysis and all were found to carry a DNA segment encoding the N-terminal sequence (1–11) of α-hANP. Two plasmids of this group, phANP1, harbouring the longest

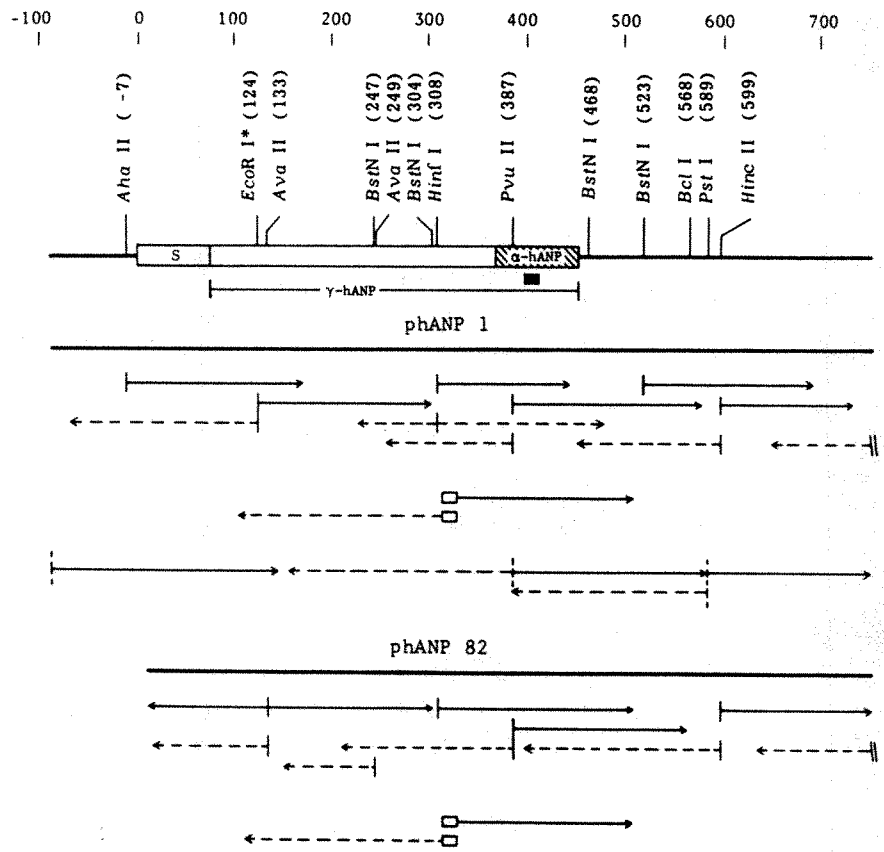

Fig. 1 Strategy of sequencing the cDNA inserts in clones phANP1 and phANP82. The restriction map displays only those restriction endonuclease sites relevant to the present work. They are identified by numbers indicating 5′-terminal nucleotides generated by cleavage. Nucleotides are numbered as in Fig. 2. S, Coding region for putative signal peptide; ▨, coding region for α-hANP; ■, region of the sequence of synthetic oligodeoxyribonucleotides used in probing cloned cDNAs. The direction and extent of sequence determinations are shown by arrows (→, upper strand; ---›, lower strand). The sites of 5′- and 3′-end-labelling are indicated by short vertical lines at the ends of arrows. Double slashes indicate that 5′-end-labelling was done on the sites located on the vector DNA. Dotted lines mean that the transcription primed by the general primers was started from sites located on the pUC8 plasmid[18]. Open boxes at the end of arrows indicate the region of the primer sequence detailed below.

Methods: The clones were obtained as follows. One mg of total RNA was extracted[19] from atria of an 87-year-old female and a 61-year-old male post mortem. A total of 75 μg of poly(A)$^+$ RNA was isolated by oligo(dT)-cellulose binding procedure[20] using 10 mM Tris–HCl buffer, *p*H 7.2 containing 0.5 M $LiCl_2$, 10 mM EDTA and 0.5% SDS as a binding buffer. A cDNA library was constructed by the method of Okayama and Berg[7] using 15 μg of poly(A)$^+$ RNA and 4.2 μg of the vector-primer. *Escherichia coli* WA802 was used for transformation. Approximately 40,000 ampicillin-resistant transformants were obtained per μg of starting mRNA and screened by hybridization[21] at 38 °C for 16 h with the 5′-^{32}P-labelled mixtures of oligo I and oligo II. A second hybridization was done on the 85 positive clones with similarly labelled oligo I and oligo II at 40 °C and 38 °C for 16 h respectively. Plasmids were isolated from 8 clones out of 23 which hybridized with oligo II but not with oligo I. The chain-terminator nucleotide-sequencing method of Sanger *et al.*[22] using oligo II as a primer showed that all 8 plasmids carried an insert which contained the coding sequence corresponding to the first 11 amino acids of α-hANP. Two plasmids, phANP1 and phANP82, having the longest inserts (about 950 bp and 850 bp respectively), were used for further sequencing by the following methods. *a*, Maxam–Gilbert method[23]; *b*, method of Sanger *et al.*[22], using as primers oligodeoxyribonucleotides of the sequences 5′-GATCGATCTGCCCTC-3′ and 3′-CTAGCTAGACGGGAG-5′ for lower and upper strands respectively; *c*, method of Sanger *et al.*[22] after cloning three fragments of the insert generated by digestion with *Pst*I and *Pvu*II endonucleases into pUC8 plasmid[18].

cDNA insert of about 950 base pairs (bp) and phANP82 (about

```
        Met Asp Arg Ile Gly
3′-TAC CT(G/A) GC(T/G/C/A) TA(T/G/A) CC-5′    (oligo I)

3′-TAC CT(G/A) TC(T/C) TA(T/G/A) CC-5′        (oligo II)
```

850 bp), were sequenced according to the strategy indicated in Fig. 1 legend.

Figure 2 depicts the complete nucleotide sequence of the cDNA insert of the phANP1 plasmid which is 843 bp long (excluding poly(A) sequence). All of the 3′ portion of the mRNA upstream of the poly(A) tail[9] was represented in the insert because about 80 consecutive A residues were found at the 3′ end. Most of the 5′ end portion of the mRNA also seems to be represented in the insert, because none of 58 independently isolated transformants had plasmids with an insert appreciably longer than that of phANP1 on cleared lysate analysis[10].

The nucleotide sequence of phANP1 has a single large open reading frame, the first ATG codon appearing as 91–93 nucleotides from the 5′ end (nucleotide residues 1–3 in Fig. 2). A TGA termination triplet is found 151 codons later. The 3′-untranslated region of 300 nucleotides contains the hexanucleotide sequence AATAAA (underlined in Fig. 2), which is known to precede polyadenylation sites in many eukaryotic mRNAs[11].

Figure 2 shows the amino acid sequence deduced from the 151 codons. The sequence of nucleotide residues 370–453, encoding amino acids 124–151, corresponds precisely to the amino acid sequence of α-hANP. In addition, residues 26–151 deduced from the base sequence 76–453 in the cDNA corresponds exactly to the natriuretic polypeptide of MW 13,000, designated γ-hANP, which has been recently identified in human atrial tissue. The complete sequence of 126 amino acids of γ-hANP has been established in our laboratory as starting from H-Asn-Pro-Met-Tyr-Asn- at its N-terminus and ending in -Asn-Ser-Phe-Arg-Tyr-OH at its C-terminus; α-hANP is the C-terminal 28 residues of γ-hANP (details to be published elsewhere).

In the cDNA sequence, the TAC codon for the C-terminal Tyr of γ-hANP is followed by the translational termination codon TGA. Therefore, the protein translated from the reading frame is apparently a precursor for both γ-hANP and α-hANP, and we have called the precursor pre-human atrial natriuretic polypeptide (pre-hANP).

The 25 amino acid residues preceding the γ-hANP sequence exhibit features characteristic of a signal peptide which is usually present at the N-terminal end of precursors of secreted proteins[12,13]. The hydrophobic core[14] corresponding to amino acids 9–20 includes 10 hydrophobic residues and is followed, 5 amino acids later, by an alanine residue at position 25, which very often occurs before the cleaving site of signal peptides[14]. The appreciable sequence similarity between the signal peptides of the precursor for α-hANP and human preproen-

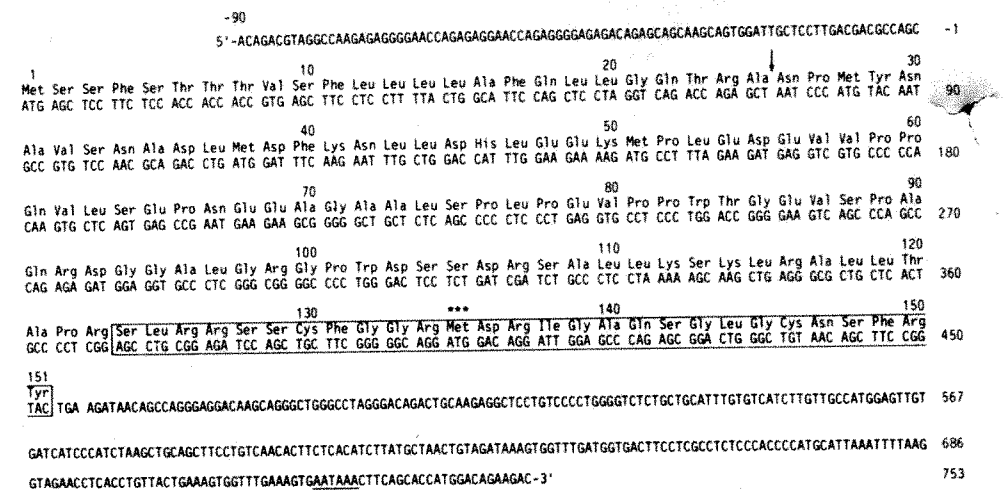

Fig. 2 Nucleotide sequence of plasmid phANP1 cDNA insert and deduced amino acid sequence of the precursor for α-hANP. The nucleotide sequence of phANP1 and phANP82 cDNA inserts were determined as described in Fig. 1 legend. Both sequences coincided except for 99 5′-terminal nucleotides shown in the figure which were missing from the phANP82 insert. Nucleotide residues are numbered in the 5′ to 3′ direction, beginning with the first residue of ATG triplet encoding the initiator methionine. Nucleotides on the 5′ side of residue 1 are indicated by negative numbers. The predicted amino acid sequence of the precursor for α-hANP is displayed above the nucleotide sequence, and its amino acid residues numbered beginning with the initiator methionine. Boxed sequence is of α-hANP. The arrow indicates the most likely processing site for signal peptidase. The hexanucleotide which precedes the site of polyadenylation in many eukaryotic mRNAs[11] is underlined.

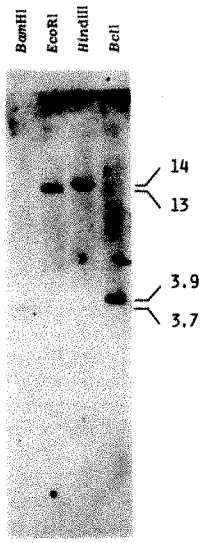

Fig. 3 Hybridization of human genomic DNA with a ^{32}P-labelled cDNA probe from plasmid phANP82. High-molecular-weight human DNA (8 μg) isolated from peripheral blood lymphocytes of several individuals by the procedure of Gross-Bellard *et al.*[24], using pronase instead of proteinase K, was digested to completion with 40 U each of various restriction endonucleases, electrophoresed on 1.0% agarose gel and blotted to a nitrocellulose filter[25]. The ^{32}P-labelled DNA probe was prepared from a 608-bp *Pst*I fragment (nucleotides 10–588 plus 29 G residues extended from nucleotide 10 of Fig. 2) of the cDNA insert of phANP82 as described previously[26]. 1.4×10^7 c.p.m. of the probe were hybridized with the filter for 16 h at 65 °C and then washed as described[27]. Numbers on the right of the figure indicate the size of the hybridized DNA fragment in kilobase pairs.

kephalin A[15] (Met-Ala-Arg-Phe-Leu-Thr-Leu-Cys-Thr-Trp-Leu-Leu-Leu-Leu-Gly-Pro-Gly-Leu-Leu-Ala-Thr-Val-Arg-Ala, where indicated amino acid residues are underlined) was noted.

The direct connection of γ-hANP to the putative signal sequence suggests that removal of the signal peptide and disulphide bond formation may yield natriuretically active γ-hANP. Also, the location of α-hANP at the carboxyl end of γ-hANP suggests that further processing takes place after the sequence Pro-Arg (residues 122–123). Although the Pro-Arg sequence has not been regarded as a typical processing signal in the synthesis of many peptide hormones, gastrin-releasing peptide is known to be processed at a Pro-Arg sequence to yield its C-terminal decapeptide amide in the mammalian intestine[16] and spinal cord[17]. α-hANP could be similarly processed out of the precursor.

The existence of multiple peptides with natriuretic activity in human atria led us to investigate (as described in Fig. 3 legend) whether the other related hANP genes are present in the human genome. Endonucleases *Bam*HI, *Eco*RI and *Hin*dIII do not have cleavage sites in the cDNA, but *Bcl*I has a cleavage site near the *Pst*I site (Fig. 1). The fragment to the right of the *Bcl*I site would not be expected form a stable hybrid with the probe used because the complementary sequence region is only 21 nucleotides long. A single hybridizing DNA fragment can be seen in each lane of the gel (Fig. 3), which strongly suggests the existence of a single gene for hANP precursor in the human genome, although the presence of multiple genes comprising a repetition of the same sequence cannot be excluded.

The way ahead...

British Journal of Pharmacology

Published monthly on behalf of the British Pharmacological Society, the British Journal of Pharmacology contains original papers submitted from all parts of the world making it one of the most respected journals for all those professionally involved in the pharmacological sciences. It contains up-to-date papers of the highest quality on all aspects of drug action and is thus a vital source of information for physiologists, clinicians, immunologists, molecular biologists and biochemists as well as pharmacologists.

HUMAN TOXICOLOGY

An International Journal

Published bi-monthly this new journal features the following material:

* original papers of a high scientific standard on all aspects of human toxicology, embracing both animal research and studies with humans
* short communications
* invited comment on current matters of professional interest
* editorials on topical issues
* review papers
* book reviews

Pharmaceutical Medicine

New For 1984...

A new, independent, quarterly journal for the critical assessment of new and old methods employed to test drugs in man. To promote the discipline of pharmaceutical medicine and cover those activities germane to human testing of drugs, papers will appear on human pharmacology, clinical investigation, comparative clinical trials, and epidemiological studies. The latter will inevitably be associated with drug safety and post-marketing surveillance. The problems of quality control and analysis of laboratory tests will be addressed, and the handling of clinical trial data. The design and statistical analysis of clinical studies will also feature.

Pharmaceutical Medicine will provide invited contributions, reviews, news and opinion. A major feature will be abstracts of papers published elsewhere giving new means of assessing drugs.

The Journal will not take an overtly political or commercial position, but any matters affecting ways and means of assessing drug efficacy and safety, including governmental regulations, will be discussed.

Subscription Rates
UK and Eire: £45.00, USA/Canada: Surface US $95.00, Rest of World: Surface £63.00

British Journal of Anaesthesia

The British Journal of Anaesthesia has consistently been the leading independent journal in anaesthesia enjoying international contributions and readership.

Published monthly the journal offers:

* Sections on laboratory investigation, clinical research, case reports and information on apparatus.
* A correspondence section in which views are exchanged through short communications and comments on matters of professional interest.
* Book Reviews.
* Postgraduate Educational Issues, on both clinical and basic themes, produced twice a year – indispensable to established clinician and trainee alike.

Subscription Prices UK £38.50, USA/Canada US $90.00,
Rest of World £53.00 surface, £95.00 airmail,
Trainee rates UK £24.00, US $50.00.

The British Journal of Cancer

Published monthly on behalf of the Cancer Research Campaign, The British Journal of Cancer is one of the leading cancer journals in the world, publishing articles in all the major scientific disciplines relevant to the subject. The journal provides papers and short communications submitted by scientists from countries throughout the world. In addition, the Proceedings of the meetings of the British Association for Cancer Research are regularly published in the journal. From time to time other selected national and international meetings are also covered. Up-to-date book reviews appear in each issue.

Subscription Prices
UK £99.00, USA/Canada US $240.00 surface,
US $285.00 airmail,
Rest of World £124.00 surface,
£160.00 airmail.

Excitotoxins

Volume 39 in the *Wenner-Gren International Symposium Series*

Edited by
Kjell Fuxe
Department of Histology, Karolinska Institutet, Stockholm, Sweden
Peter Roberts
Department of Physiology and Pharmacology, University of Southampton, England
Robert Schwarcz
Department of Psychiatry, University of Maryland School of Medicine, USA

£35.00; *c* 390pp; ISBN 0 333 361520

This book describes the fundamental properties of the glutamate-aspartate neuron system of the central nervous system and how the neurotoxic and excitatory effects of endogenous and exagenous excitotoxins, such as ibotenic and kainic acid, may be mediated by glutamate-aspartate synapses. The clinical implications of this research for the understanding of the pathophysiology of Huntington's Chorea, temporal epilepsy, dementia, and ageing are also reviewed

Contents

Session I – Excitotoxic amino acids: localization, chemistry, physiology, pharmacology and biochemistry – Identification of excitatory amino acid pathways in the mammalian nervous system – *F.Fonnum, V.M.Fosse and C.N.Allen;* Electrophysiological actions of kainate and other excitatory amino acids, and the structure of their receptors. – *H.McLennan, G.L.Collingride and S.J.Kehl;* Two types of excitatory amino acid responses in the cat caudate nucleus – *P.L.Herrling;* Recent advances in the pharmacology of excitatory amino acids in the mammalian central nervous system – *J.Davies, R.H.Evans, A.W.Jones, K.N.Mewett, D.A.S.Smith and J.C.Watkins;* Alteration by kainate of energy stores and neuronal-glial metabolism of glutamate *in vitro* – *W.J.Nicklas;* Receptors for excitotoxins – *P.J.Roberts and G.A.Foster;* **Overview Lecture –** Excitotoxins: An overview – *J.W.Olney;* **Session II – Mechanisms of Excitotoxicity –** Neuronal degeneration after intracerebral injections of excitotoxins. A histological analysis of kainic acid, ibotenic acid and quinolinic acid lesions in the rat – *C.Köhler;* Kainic acid: Insight into its receptor-mediated neurotoxic mechanisms – *J.T.Coyle, J.Ferkany, R.Zaczek, J.Slevin and K.Retz;* The neurodegenerative properties of intracerebral quinolinic acid and its structural analog cis-2,3-piperidine dicarboxylic acid – *R.Schwarcz, W.O.Whetsell Jr. and A.C.Foster;* Studies on excitatory amino acid receptors and their interactions and regulation of pre- and postsynaptic dopaminergic mechanism in the rat telencephalon – *K.Fuxe, L.F.Agnati, M.F.Celani, F.Benfenati, K.Andersson and J.Collins;* Electrophysiological and pharmacological studies on kainic acid-induced neuronal activation – *C.De Montigny, G.de Bonnel and D.Tardif;* An analysis of bioelectrical phenomena evoked by microiontophoretically applied excitotoxic amino-acids in the feline spinal cord – *I.Engberg, J.A.Flatman, J.D.C.Lambert and A.Lindsay;* The role of seizures in kainic acid induced brain damage – *Y.Ben-ari;* Excitatory amino acid transmitters in cerebellum and optic tectum – *M.Cuenod, A.Dilber, H.Henke, G.Toggenburger, L.Wiklund and M.Wolfensberger;* Mechanisms of excitotoxins examined in organotypic cultures of rat central nervous system – *W.O.Whetsell Jr. and R.Schwarcz;* **Session III – Excitotoxins as Tools in Neuroscience –** Ibotenate as a tool in neurobiology. Studies on dopaminergic and cholecystokinin immunoreactive neurons after ibotenate induced lesions – *K.Fuxe, L.F.Agnati, P.Frey, C.Köhler, M.F.Celani, K.Andersson, N.Battistini, C.Farabegoli and R.Schwarcz;* Characterisation of striatal ibotenate lesions and of 6-hydroxydopamine induced nigral lesions by morphometric and densitometric approaches – *L.F.Agnati, K.Fuxe, L.Calza, F.Benfenati, N.Battistini, I.Zini, L.Fabbri and M. Goldstein;* Effects of ibotenic acid stereotactically injected into striatum or hippocampus on local bood flow and glucose utilisation in rats – *C.Owman, J.Andersson, N.H.Diemer and K.Fuxe;* Synaptic rearrangements in the kainic acid model of ammon's horn sclerosis – *J.V.Nadler, D.L.Tauck, D.A.Evenson and J.N.Davis;* On the problem of distant lesions in behavioural studies utilising kainic acid – *H.C.Fibiger and S.Atmadja;* Kainic acid injections into the rat neostriatum: Effects on learning and exploration – *M.Pisa;* Effects of neurotoxic excitatory amino acids on neuroendocrine regulation – *C.B.Nemeroff;* **Session IV – Clinical Aspects –** Adverse reactions in humans thought to be related to ingestion of elevated levels of free monosodium glutamate (MSG) (Chinese Restaurant Syndrome and Other Reactions) – *L.Reif-Lehrer;* Temporal lobe epilepsy, excitotoxins and the mechanism of selective neuronal loss – *T.Griffiths, M.C.Evans and B.S.Meldrum;* Huntington's disease: Anti-neurotoxic therapeutic strategies – *I.Shoulson;* Excitotoxicity in ageing and dementia – *D.M.Bowen, C.C.T.Smith and A.N.Davison.*

Astrophysical consequences of n–n̄ oscillations

SIVARAM and KRISHAN[1] have suggested that the anomalously high flux of low-energy antiprotons observed in cosmic rays[2] is produced when free neutrons, which are possibly ejected in supernova explosions, undergo neutron–antineutron (n–n̄) oscillations as expected in some grand and partially unified theories[3]. Such oscillations are strongly suppressed in an external magnetic field[3–6] but by choosing the interstellar field strength, B, to be as low as 10^{-7} G and an oscillation time, $\tau_{n-\bar{n}} = 10^5$ s, these authors obtain[1], $\bar{n}/n \approx 10^{-4}$. Because n̄ and n β-decay to p̄ and p respectively, this implies $\bar{p}/p \leq 10^{-4}$, which compares with the observed value[2], $\bar{p}/p = (2.2 \pm 0.6) \times 10^{-4}$ at ~130–370 MeV/n. (Contrary to their[1] remark, the ratio p̄/p cannot exceed the ratio n̄/n, regardless of the number of neutrons ejected per proton in a supernova.)

However, before this suggestion, old limits on the stability of nuclear matter had been used to infer[4–6] $\tau_{n-\bar{n}} > 10^6$–5×10^7 s. Also, direct observations of free neutron beams had yielded the limit[7], $\tau_{n-\bar{n}} > 1.2 \times 10^5$ s, and this has been recently improved to[8] $\tau_{n-\bar{n}} > 10^6$ s. Furthermore, the interstellar magnetic field strength must be $> 10^{-6}$ G to account for observations of pulsar signals[9] and the galactic synchrotron background[10]. (We disagree that this value is ". . given by equipartition arguments . . (with) . . no physical basis . . "[1].) Thus, using these conservative limits, we obtain $\bar{n}/n \approx \bar{p}/p < 10^{-8}\ (\tau_{n-\bar{n}}/10^6\ \mathrm{s})^{-2}\ (B/10^{-6}\ \mathrm{G})^{-2}$. Moreover, this obtains at ~1 MeV/n, corresponding to the typical ejection velocity of $\sim 10^4$ km s^{-1} in a supernova. Thus the observation that $\bar{p}/p \sim 10^{-4}$ at ~200 MeV/n cannot be accounted for by this mechanism.

Note that even in the total absence of a magnetic field, neutrons would sooner β-decay than oscillate into antineutrons. This sets an absolute upper limit $\bar{n}/n < 10^{-6}\ (\tau_{n-\bar{n}}/10^6\ \mathrm{s})^{-2}$, thus making this process uninteresting in any conceivable astrophysical or cosmological context.

I thank Professor D. W. Sciama for discussions.

SIVARAM AND KRISHAN REPLY—We have not stated anywhere in our paper[1] that all of the 10^{57} neutrons ejected by a single supernova are at an energy ~200 MeV, in which case there would indeed be an excess of energy involved. The only claim made is that here is a possible mechanism for directly producing p̄ at low (MeV) energies without any need for deceleration from energies of several GeV (with its attendant difficulties) inevitable in most models.

Second we felt that there was no need for Sarkar to have written down all the formulae for n–n̄ transition probabilities. These are well known and are the same formulae that we used. In fact for a $B = 10^{-7}$ G and $\tau_{n-\bar{n}}$ of 10^5 s, he also obtains $\bar{n}/n \sim 10^{-4}$. Regarding his chief point of contention that the strength of the interstellar magnetic field must be $\sim 10^{-6}$ G; we are surprised that Sarkar has overlooked the fact that in the latter half of our paper we have pointed out that if this field is assumed it would considerably lower $\bar{p}/p\ (< 10^{-6})$. (For 10^{-6} G, $\Gamma_B \gg \Gamma_{n-\bar{n}}$, and for 10^{-7} G, they are just equal.) We went on to point out that to build up the observed low-energy background of 10^{55} antiprotons in our Galaxy (as implied by the observed density of 10^{-4} eV cm^{-3}) we would require a few thousand explosions which would occur in periods $\sim 10^6$ yr which is the same order as the diffusion time for the produced particles to spread over the Galaxy and produce the observed background. More generally one can say that the number of antiprotons produced is

$$\bar{p} = N \left(\frac{\Gamma_{n-\bar{n}}}{g u_N B} \right)^2 f t, \qquad \Gamma_{n-\bar{n}} = \hbar / \tau_{n-\bar{n}}$$

where N is the number of neutrons per supernova, f the frequency of explosions and t the diffusion time $\sim 10^5$ yr. Thus if all low-energy antiprotons ($\bar{p} = 10^{55}$) in the Galaxy were produced by supernovae, then with $N = 10^{57}$, $f = 1/10$ yr, we would have an astrophysical constraint on the oscillation time $\tau_{n-\bar{n}}$. If $\tau_{n-\bar{n}} > 10^7$ s (as indirect evidence suggests), of course, the p̄ production would be too low. Measurements of p̄ should perhaps be made over a few MeV as this is the range where most supernova neutrons are produced.

Formation of sapropels in the Tyro Basin

WE were most interested in the two companion papers pertaining to the recent formation of sapropels in the Tyro Basin, an isolated depression within the Hellenic Trench in the eastern Mediterranean Sea. Certainly the physiography within this trench system would be conducive to allowing localized near-bottom anoxia because of limited bottom water ventilation as related to outcrops of Messinian salt, as well pointed out by Jongsma *et al.*[1] and de Lange and ten Haven[2].

We are concerned, however, with their statement: "Assuming an undisturbed sedimentation and taking a relatively high sedimentation rate of 5 cm kyr^{-1}, we conclude that the recovered sediment column of 400 cm of solely sapropel to sapropelic sediment indicates a period of at least 80,000 yr."

Instead, we suggest that the 4-m long section was deposited in much less time. There is ample evidence of resedimentation events in similar isolated basins during the recent geological past and the present throughout the Hellenic Trench system[3–5], as well as on the Mediterranean Ridge immediately south of the trench[6,7]. In particular, redeposited sapropels have been identified in dated piston cores from these regions. Gravity-driven processes triggered by the active tectonism in the region have resulted in stratigraphically displaced and expanded-thickness sapropel sections[8,9], sometimes in excess of 4 m, and in dilution of organic matter content. As a result of this prevalent resedimentation process, cores from the trench show some of the highest sedimentation rates (to >400 kyr^{-1}) yet measured in the Mediterranean Sea[4]. Thus, their conclusion of a 400-cm long sapropelic section representing 80,000 yr of undisturbed sedimentation is unrealistic. It is equally plausible that at least part of the sapropelic section cored in the Tyro Basin is redeposited, and equivalent to the upper sapropel (S_1) dated at ~8,000 yr BP and mapped over much of the eastern Mediterranean.

TROELSTRA *ET AL.* REPLY—We agree with McCoy and Stanley's view that the age at the bottom of the Tyro Basin core must be considerably younger than we had assumed in our papers, which were mainly based on shipboard observations. Shore-based analyses, still in progress, have produced different data. Because of the different bottom water regimes in the Tyro and Kretheus basins, we would like to consider each basin separately.

First, we want to stress that, at present, conditions suitable for sapropel formation, namely an anoxic and reducing environment due to halocline water stratification, do exist in the Tyro basin. Laboratory studies on core P46 indicate that sediments were not deposited in exclusively pelagic conditions. The most important argument for this is the presence of fining-upward sequences in the core, indicating transport by mass-flows. Furthermore, faunal and floral composition through the core is rather uniform and suggests a relatively warm climate. If the age at the bottom of the core were 80,000 yr, a fluctuating faunal and floral pattern would be expected, due to climatic changes. Moreover, the presence at the bottom of the core of well-preserved algae, one species still in possession of bright green-coloured chlorophyll, indicates that little or no diagenesis took place. This is contrary to what one would expect if the sediments were deposited at 80,000 yr BP.

In contrast to the Tyro Basin, bottom waters in the Kretheus Basin are well-ventilated at present. Core P45 consists of alternate dark-coloured (? resedimentated sapropel) and lighter-coloured sediments. The latter contain abundant sand-sized grains of metamorphic rock indicating that sedimentation in the Kretheus Basin is also governed by mass-flow transport. Planktonic foraminiferal composition through the core is comparable with that in core P46.

We conclude that sedimentation rates in both basins must be high. At this stage, pending ^{14}C analyses, an entire Holocene age for both cores cannot be excluded. Resedimented S1 may be one of the major contributors to the sapropelic intervals in the cores, as correctly assumed by McCoy and Stanley.

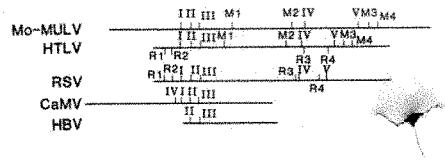
Sequence similarity among retroviruses—erratum*

RECENTLY Toh *et al.*[1] reported the existence of amino acid sequence similarity between the reverse transcriptase of certain retroviruses and the DNA polymerases of cauliflower mosaic virus (CaMV) as well as a region of hepatitis B virus (HBV) that probably encodes a DNA polymerase. For completeness, we draw attention to other regions of protein similarity between retroviruses (human T-cell leukaemia virus, HTLV; Moloney murine leukaemia virus, Mo-MuLV; and Rous sarcoma virus, RSV), HBV and CaMV that were not reported by Toh *et al.*

The sequences are presented in Table 1 and the relative positions of the similar regions indicated in Fig. 1. The common set of amino acids discussed by Toh *et al.* is conserved in the amino-terminal region of all retrovirus reverse transcriptases studied (regions I–III). These common sequences are located near the amino-terminus of the HBV protein and the centre of the CaMV polymerase. Another region of similarity, IV, not discussed by Toh *et al.*, is also found in all retroviruses and is present in the CaMV protein. Region V, reported by Toh *et al.*, to be present in Mo-MuLV and RSV, is also found on HTLV. We also draw attention to sets of amino acids that are conserved with respect to sequence and relative position between the reverse transcriptases of HTLV and Mo-MuLV (M1–M4) and HTLV and RSV (R1–R4).



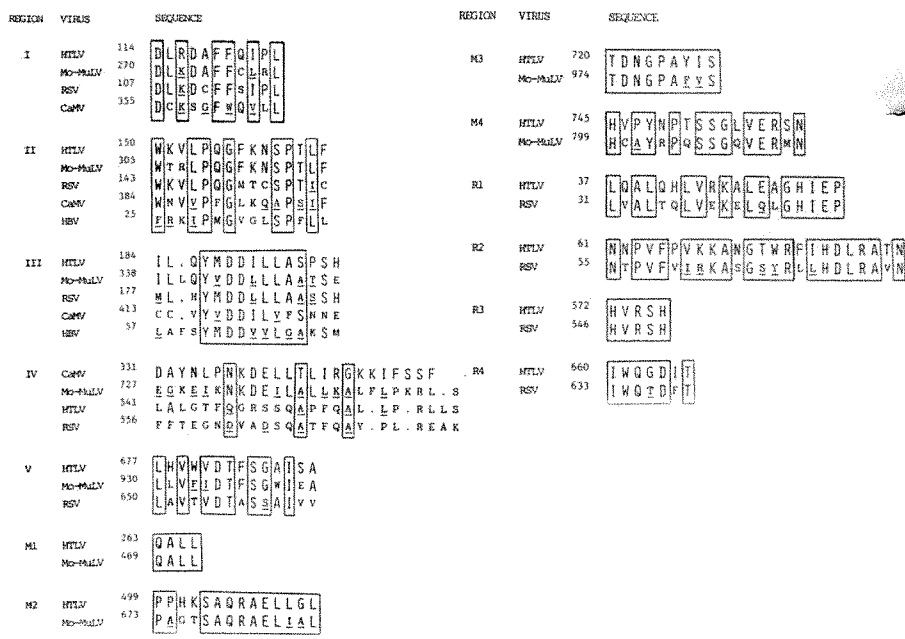


Fig. 1 Alignment of the polymerase gene products among five different viruses, depicting the regions shown in Table 1.

A Field Guide to Birds of the USSR

V.E. Flint, R.L. Boehme, Y.V. Kostin, and *A. A. Kuznetsov*
Translated by *Natalia Bourso-Leland*
Ornithological Advisor, *James Baird*

The first field guide to birds of the USSR in English, this beautiful volume describes 728 species covering a vast geographical area including much of Europe, East and Central Asia and India. This edition, a translation of the popular 1968 Soviet handbook, includes updated species information, bird sizes, range and distribution information, updated range maps, two indexes, and translator's advice to bird watchers traveling in the USSR.

MECHANISMS OF MORPHOLOGICAL EVOLUTION

A Combined Genetic, Developmental and Ecological Approach

by **W. Arthur,** *Department of Biology, Sunderland Polytechnic*

As the title implies, this book is about the evolution of developmental systems in general rather than specific evolutionary pathways. It is written by a biologist, and aims to integrate quantitative and ecological genetics, evolutionary ecology and developmental biology; this synthesis provides stimulating new insights into the development and long term evolution of morphological characters. Although the potential reader is assumed to have fairly extensive biological knowledge, advanced mathematics are not required.

BIOLOGICAL MACROMOLECULES AND ASSEMBLIES

Volume 1: Virus Structures

edited by **F. Jurnak** and **A. McPherson,** *both of University of California, Riverside*

This volume presents the most impressive recent achievements of macromolecular analysis by x-ray diffraction methods, focusing on the study of the structures of the viruses. It offers examples of icosahedral or spherical plant viruses, helical plant viruses, filamentous phages, and initial investigations of more complex icosahedral animal viruses.

0471 87077 3 408pp June'84 £69.25

GROWTH AND MATURATION FACTORS, Volume 2

edited by **G. Guroff,** *National Institutes of Health*

This volume continues to survey growth factor research, presenting the most recent discoveries on erythropoietin, sciatin, and various other muscle trophic factors, tumor and related angiogenesis factors, prostaglandins and proliferation of cultural animal cells, growth promoting factors in human and bovine milk, T-cell growth factor, and affinity labeling of receptors. It presents unfolding information from several points of view.

ORDERS AND FAMILIES OF RECENT MAMMALS OF THE WORLD

edited by **S. Anderson,** *The American Museum of Natural History, New York,* and **J.K. Jones, Jr.,** *Texas Tech University*

A comprehensive, quick reference summary of the orders and families of living and recently extinct mammals of the world. This convenient, one-source reference provides ready access to information on diagnostic features, general characteristics, habits, habitats, distribution, and genera. It includes an extensive bibliography.

0471 08493 X 700pp June'84 £54.40

PHOTOSYNTHESIS

by **C. Foyer,** *Sheffield University*

A concise, yet comprehensive description of the photosynthetic pathways, their regulation, and interrelationships. The book focuses on higher plants but considers algae and bacterial systems as well. It also indicates the ways in which plants adapt to the environment.

Series: Cell Biology: A Series of Monographs

Contents: General Concepts; The Photosynthetic Membranes; Interactions Between the Thylakoids and Stroma; The Reductive Pentose Phosphate Pathway; The Role of the Chloroplast Envelope; The End Products of Photosynthesis in Leaves; C4 Metabolism; Crassulacean Acid Metabolism (CAM); Photorespiration; Index.

0471 86743 0 240pp June'84 £29.65

DEVELOPMENTAL BIOLOGY OF CULTURED NERVE, MUSCLE, AND GLIA

by **D. Schubert,** *The Salk Institute, San Diego*

This presents a discussion of differentiation and cell-cell interactions in biology. The book outlines the history of cell culture, focuses on the advantages and limitations of cultured cells for the study of cellular differentiation, describes the work of the past decade, and discusses extracellular macromolecules and cellular adhesion. Where possible, it is written from the vantage point of the individual experiments which clarified major issues.

0471 86592 3 332pp June'84 £49.45

IMMUNOLOGY

The Science of Self-Nonself Discrimination

by **J. Klein,** *Max-Planck-Institut fur Biologie, Tubingen*

This introductory text stresses the biological approach to immunology. The first section explains what immunology is and how immunological processes might have originated. Part Two offers detailed views of immunologically important organs and tissues, their origin and pathology. An in-depth analysis of macrophages, T lymphocytes, and B lymphocytes is offered in Part 3, while Part 4 synthesizes the text, explaining how bodies defend themselves from external and internal insults. The well-illustrated text includes appendices that summarise fundamental background information.

Of Mice, Models, and Men: A Critical Evaluation of Animal Research.
By Andrew N. Rowan.
State University of New York Press: 1984. Pp.323. Hbk $34.50; pbk $12.95.
Man and Mouse: Animals in Medical Research.
By William Paton.
Oxford University Press: 1984. Pp.192. Hbk £9.95; pbk £2.95.

AS Andrew Rowan says on p.31 of his book, "research on animals touches a very raw nerve in some people". Those who protest do so from diverse motives — they may identify with the helplessness of the animal or argue against "speciesism" as against sexism, racism and slavery. Some fight research they consider to be wasteful and frivolous, while others fear scientific progress of any kind. In recent years activist movements (reflecting the growth of violence in other spheres) have organized angry, destructive demonstrations; research animals are "liberated" and

> terrorist groups break into laboratories and use letter bombs to intimidate those who dare to remind the public of the advances in curative medicine and in public health that have followed from experiments on living animals [Sir Andrew Huxley in the foreword to *Man and Mouse*].

Yet, at the same time, there is a more intelligent, growing public concern about the way in which animals are used in laboratories. Although there is need for debate, biomedical scientists have sometimes been unwilling to talk.

The appearance of two excellent, outspoken books, one from each side of the Atlantic, is well timed. Andrew Rowan from Tufts University School of Veterinary Medicine, has a clear appreciation of the value and necessity of animal experiments but for long has waged a campaign for animal welfare, for the introduction of effective United States Government legislation and for a reduction in the numbers of animals used in what he considers to be wasteful or unnecessarily painful experiments.

Rowan feels that "the old platitudes and the arrogant cliché that doctor knows best are no longer sufficient in the face of a more sophisticated approach by the animal welfare movement". He deals with the history of animal research in the United States and with the attitudes and assumptions it evoked, lists the numbers of animals used, attempts to assess the pain and suffering caused, and discusses the "rights" of animals. He thinks that too many animals are used needlessly in education at all levels and deplores the "science fairs" that lead to unnecessary suffering of animals at the hands of high-school students. He also criticizes the work of the primate centres, various aspects of behavioural, psychological and other studies, and gives examples to support his belief that biomedical knowledge is being advanced at too great a cost in animal suffering. He believes that there is an opportunity for a great reduction in the wastage of animals in toxicological tests and for the revision of the requirements of the statutory bodies that demand them.

Sir William Paton, of the Department of Pharmacology in Oxford, has written a thoughtful, philosophical book that covers much of the same ground but from a different viewpoint. His objective is to make a strong case for *responsible* experimentation on live animals, and to look to the future. While there has been legislation in Britain on the conduct of animal experiments for more than 100 years, the Act of Parliament of 1876 is in course of revision and there is a European Convention on the use of animals in research.

In a reflective discussion of the ethical questions, Paton finds that the characteristic that gives human life a special value, different in quality from the lives of other animals, is the capacity to accumulate experience by the spoken, written and printed word and all that flows from it — the capacity to consent, to ask moral questions, to feel moral obligations and to feel responsible for animals. He finds no basis for claims that animals have "rights" (a human social concept linked with duties), but distinguishes between humans as moral *agents* and animals as moral *objects*, in respect of which humans accept duties. "Animal rights" may be replaced, with some gain, by the "moral worth of animal life".

Paton shows how, from the earliest times, accumulated knowledge from animal experiments (deliberate attempts to discover what was not yet known) has yielded great benefits for human and animal health. Many of these benefits were derived from work undertaken to acquire basic knowledge, with no particular benefit in view. Many problems still remain to be solved, especially in the control of diseases of impoverished, developing countries, and Paton warns that unreasonable harrassment and restriction of the efforts to acquire new knowledge is likely to inhibit advance and cause unnecessary human and animal suffering. Of all forms of animal suffering — and the "natural" life of animals in the wild is full of stress and tragedy — only that incurred by experiment, and the medical and veterinary practice based on it, offers the prospect of reducing further suffering and misery.

Both authors agree that the problem is to strike a balance and that Russell and Burch's "3 Rs" (put forward in *The Principles of Humane Experimental Technique*; Methuen, 1959) should be applied to all animals in experimental work — *replacement* by alternatives when possible, *reduction* in numbers and *refinement* of method. To these Paton adds a fourth, *responsibility* of the experimenter, a concern shared with the world outside the laboratory. Rowan and Paton agree that deliberate funding of research into methods for the relief of pain in animal experiments would be of advantage, and Rowan would like to see much more money available for the study of alternatives to animals. They agree that the LD_{50} test (originally designed for the accurate assay, against a standard, of the toxicity of agents such as diphtheria toxin in the preparation of vaccines) has been misapplied to substances for which an approximate measure of toxicity, using fewer animals and causing less suffering, would be more appropriate. They agree also that the statutory requirements laid down by official bodies for testing drugs and other chemicals should not be allowed to go unchallenged, but that tests should be discontinued when superseded by methods using less animals, causing less suffering or dispensing with animals altogether.

The paradox is that, along with public concern with the plight of experimental animals, there is increasing demand for drugs, foods and household products to be "safe". Safety testing, for a long time to come, will involve the use of animals. Television and radio programmes often report exciting advances in medicine, surgery and biology based on animal experiments without drawing attention to the essential part of such experiments, together with a rational mixture of non-animal and human experiment, in achieving the advance. Sensational accusations hit the headlines of popular newspapers which seldom give coverage when such accusations have been shown to be without foundation. The truth, it seems, is not news.

The debate will continue. As Sir Peter Medawar says:

> In the meantime we must grapple with the paradox that nothing but research on animals will provide us with the knowledge that will make it possible for us, one day, to dispense with the use of them altogether [*The Hope of Progress*; Methuen, 1972].

That debate will be all the better informed if the various protagonists read both of these books. □

Honeyed history

John B. Free

The Archaeology of Beekeeping.
By Eva Crane.
Duckworth/Cornell University Press: 1984. Pp.360. £25, $39.50.

THE history of man's relationship with the bee is a long and fascinating one; throughout the ages artists and poets have expressed appreciation of the bounty of the hive and the supposed virtue and selfless toil of the bee.

On the dust cover, the publisher claims that this is the first book "to explore the rich heritage of beekeeping archaeology". This is not true. However, earlier books in English that dealt exclusively with the history of beekeeping — among them Hilda M. Ransome's classic *The Sacred Bee in Ancient Times and Folklore* (of which a reprint is long overdue) and two works by H. Malcom Fraser, *Beekeeping in Antiquity* and *History of Beekeeping in Britain* — are no longer in print. During the past few years several other books have also included historical accounts of beekeeping. Nevertheless Dr Crane's book is a welcome and authoritative addition to the subject. Indeed it ranges more widely than its title implies and could more appropriately be called *A History of Beekeeping.*

Dr Crane provides detailed information on the latest archaeological and anthropological discoveries, notable among which are rock paintings depicting bee nests and honey-hunting in Zimbabwe, South Africa, Australia and central India. These and the long-known Spanish rock paintings are considered in relation to the honey-hunting techniques, still practised by primitive peoples in many parts of the world, to rob wild honeybee colonies of their honey and brood.

From Egyptian tomb paintings, ranging from 2400 to 600 BC, we obtain our first evidence of bees being kept in hives and of the harvesting and packing of honey into pottery vessels for later consumption. Horizontal stacked hives as depicted in the paintings are still to be seen today in Arab villages. Only a few Greek pottery hives and no Roman ones have been excavated; fortunately, however, Classical writers have left us with a wealth of information on their understanding of the honeybee colony and the types of beekeeping they practised.

During the past 2,000 years there has been a proliferation of hive types and methods of beekeeping, each adapted to local conditions. Illustrations and descriptions are given of clay pots, hollow logs, and wicker and straw baskets that are still used as hives in many parts of the world, and were undoubtedly used more widely in the past. Knowledge about primitive hives and beekeeping methods is not merely of scholarly interest, as their use in modified form can be helpful in encouraging beekeeping in developing countries where there is often considerable potential for honey production. So it is crucial that we retain such information, and Dr Crane's book could be most helpful in furthering this end. For example, the evolution of hives with movable combs can be traced back to a Greek basket hive, which here deservedly receives considerable attention. The principles it embodies form the basis of a hive now used in East Africa and elsewhere.

Because most hives are of perishable material, few old ones have survived. However more durable material was used to form the shelters in which many of the early hives were placed. Some were kept in beehouses, each with its own access to the exterior; others in open-fronted shelters, and, most commonly in the United Kingdom, hives were kept individually in recesses — bee boles — in stone or brick walls. Bee boles were most common in the eighteenth and nineteenth centuries, and the author obviously finds them particularly fascinating. She devotes 46 pages to discussion of bee boles and 33 pages to other hive shelters; the International Bee Research Association's records of the bee boles and shelters in the United Kingdom are given in an 80-page Appendix. While it is useful to have this information brought together in published form, it occupies nearly half of the book and so unbalances the presentation somewhat and gives it a bias towards the United Kingdom.

The book is attractively produced, contains much interesting and well-documented information, and many unusual illustrations. It will be a most worthy and useful addition to the beekeeping sections of libraries □

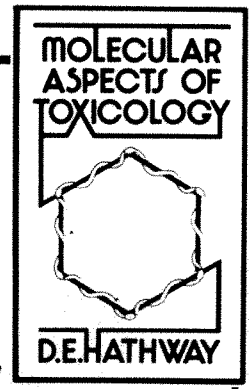
Hope for an answer

William H. McNeill

Weapons and Hope.
By Freeman Dyson.
Harper & Row: 1984. Pp.340. $17.26, £10.95.

FREEMAN DYSON, whose last book set out to disturb the Universe, addresses this one to a more modest target: ". . . the gravest problem now facing mankind, the problem of nuclear weapons from a human rather than a technical point of view" (p.3). A human point of view means, above all, a moral point of view. But it is the morality of Odysseus rather than of Achilles, that is, of the cunning survivor, not the dead hero.

The author wanders back and forth between personal reminiscence, literary discourse and strategic discussion in a delightful if sometimes confusing way for a reader who seeks a rigorous argument about how to escape the threat of nuclear annihilation. Perhaps Dyson chose this approach to emphasize the human dimension. More likely it was because he recognizes logical weaknesses in his recipe for escape from our dilemma, but wishes to insist that hope — persistent and unremitting hope — is the really important ingredient since only so can cheap despair, paralysis of will and atrophy of moral sense be forestalled.



Dyson wants a world without nuclear warheads. He asserts that with the appropriate exercise of moral indignation, political negotiation and technical investment in non-nuclear defensive systems the dismantling of the last nuclear device might be achieved after fifty years — with luck along the way. To reach this goal, American and Russian soldiers must be convinced that nuclear arms are counter-productive — unusable in war, and debilitating to the morale of the armed services in peace. Only cooperation between what he calls "warriors" and "victims" can lead to the abolition of nuclear arms. The problem, then, is to find a concept of national defence that does not depend on nuclear weapons, and then attract a robust political following in support of the military policies such a concept implies.

Dyson discovers this in what he calls "live and let live", the principle that "We maintain the ability to damage you as badly as you can damage us, but we prefer our own protection to your destruction" (p.274). This rationale, Dyson thinks, would allow the United States to negotiate with the Russians for mutual reduction of existing nuclear weaponry all the way down to zero — perhaps. Holding to the idea of mutually assured destruction (plus planning on first use of nuclear tactical weapons in case of a Soviet attack in Europe), he says, will permanently prevent successful negotiation for the simple reason that Russian doctrine concerning the use of nuclear weapons differs from that of the United States, being aimed at survival against strategic rocketry, if need be by means of counterforce first strike.

I have difficulty in imagining just how Dyson's concept of "live and let live" could be implemented. His most surprising suggestion pertains to how American strategic rockets should be targeted:

> The answer to this question is simple: We should not aim them at all. Live and let live excludes assured destruction targeting as inconsistent with the basic principle that live Americans are to be preferred to dead Russians. Limited nuclear war and counterforce targeting are excluded because they are crisis unstable, especially since we are assuming no change in the Soviet practice of counterforce targeting. What then are we to do with our strategic weapons? We must simply maintain them as best we can, making sure that they are as invulnerable as

NEW BOOK for Toxicologists

Molecular Aspects of Toxicology

By D.E. Hathway

Toxicology covers a wide field, which comprises chemical toxicology, cosmetics toxicology, environmental toxicology, food and drugs toxicology, industrial toxicology, pesticide toxicology, and the toxicology of atmospheric pollution, and which involves acute and long-term testing as well as special tests for carcinogenicity, irritation, mutagenicity and teratogenicity. In the testing phases, diagnoses are reached through the disciplines of chemical pathology, clinical medicine and pathology, and in the experimental one, explanation is sought through chemical/biochemical and pharmacological methods.

In such a fragmented field as toxicology with so many diverse practices and specialisms, it is hard to gain an idea of continuity.

This book attempts to unify the subject of toxicology and should be useful to chemists engaged in molecular biology and workers concerned with toxicology and cancer research in particular, as well as to pharmacologists and specialists in drug development and occupational hygeine and medicine in general.

Brief Contents:
Part I Toxicity of Foreign Compounds
Assessment of Toxic Risk; Structure-Activity Considerations; Measurement of a Carcinogenic Exposure;
Part II Relation between Dose and Effect and Time
Biological Action; Extension of Simple Theory to Toxicology;
Part III Metabolism
Metabolic Pathways for Industrial Chemicals and Pesticides; Kinetic Considerations;
Part IV Pharmacogenetics
Species Differences in Metabolism and Toxicity;
Part V Biochemical Lesions
Mode of Action Studies;
Part VI Chemical Carcinogenesis
Importance of Chemical Non-enzymic Reactions in Vivo; Possible Mechanisms of Carcinogenesis and their Biological Significance; Host Factors and Cellular Aspects; Tissue Specificity;
Part VII Toxicant Allergy
Antigen Formation and Immunobiological Effects Produced by Foreign Compounds;

Hardcover 319pp 0 85186 068 0
Price £27.50 ($50.00)

Leucocyte Typing

Human Leucocyte Differentiation Antigens Detected by Monoclonal Antibodies

Specification - Classification - Nomenclature

Typage leucocytaire
Antigenes de differenciation leucocytaire humains revelés par les anticorps monoclonaux: "Rapports des études communes"

Editors: **A. Bernard, L. Boumsell, J. Dausset, C. Milstein, S.F. Schlossman**

1984. 158 figures. 252 tables. 1 color poster.
XXIV, 814 pages.
Cloth DM 124,– (approx. US$46.30)
ISBN 3-540-12056-4

Leucocyte Typing comprises the proceedings of the first international collaborative effort to define human leucocyte antigens by monoclonal antibodies. Involving practically all research groups active in the field, this unusually large study was sponsored by INSERM, IUIS and WHO, who will be basing their recommendations with regard to standardization and nomenclature on the workshop results.
The book deals with technical details, surveys the large number of antileucocyte reagents that have been produced, discusses current problems, and draws conclusions concerning the future development of leucocyte typing; as such it is indispensable to the research immunologist. However, it also reviews the progress that has been made and provides a clear guide for the nonspecialist who wishes an up-to-date overview of this new field. The definition of antigens by monoclonal antigens now concerns almost all medical specialties and a study of this kind is essential for present clarity and future progress.

BEYOND VISION

Jon Darius

This book brings together 100 unique scientific photographs, chosen for their historic significance, and spanning 150 years of photography from its origins to the present day. Ranging from the submicroscopic to the cosmic, each image reveals what the human eye unaided cannot perceive. Each photograph is as fully documented as possible to describe the technique used, and its scientific significance.

Vision falls into that rare category which ...es a visual feast with an intellectual one. Page ... page overflowing with revelation and enjoyment.' *New Scientist*

'. . . the book is a most valuable contribution to the literature on the history of photography. We must hope that it will be sufficiently successful to be followed by a second selection revealing more of the wonders of scientific photography.' *Nature*

possible to Soviet attack and that they are not aimed at anything in particular. This is what it means to say that we value them as bargaining chips but not as usable military weapons. [pp.275–276].

But aimed at nothing in particular is still aimed at something — what?

Courtesy of Harper & Row.

Freeman Dyson — morality of Odysseus.

Technological development does alter war plans and can divert arms races into unforeseen paths. For example, miniaturization of hydrogen warheads drastically altered weaponry and war strategy in the 1950s and 1960s, as Dyson lucidly explains. Similar shifts in thinking may well arise in the future. New defensive weapons may make our ICBMs as obsolete as, for example, the disappearing-carriage coast artillery guns built so proudly about a century ago. But it is hard for me to imagine that new weapons will not be as destructive as those they displace. Persuading sovereign states and their military experts to substitute weaker weapons for those they have runs counter to the choices that have always been made in times past. Can the concept of "live and let live" really reverse that drift? Or is there only hope?

What I find odd about Dyson's approach is his acceptance of the existing state system as unalterable. Relocation of sovereignty is how other arms races have ended. If ours is ever to do so that seems a far more probable scenario than anything Dyson proposes. The fact that peace through subjugation is unpalatable may be why Freeman Dyson rejects this possibility without considering it. He seems to feel that it would be treason to his given name. But would it? Perhaps he should supplement Homer with Vergil, to see how empires may also find patriots and loyal subjects, profoundly grateful for the peace they bring. □

Probable ideas

Cyril Domb

Statistical Physics and the Atomic Theory of Matter, from Boyle and Newton to Landau and Onsager.
By Stephen G. Brush.
Princeton University Press: 1983. Pp.356. Hbk $45, £38.70; pbk $14.50, £12.70.

ELLIOTT Montroll, who died last December, was a leading figure in statistical physics for four decades. In a lecture delivered in 1958 entitled "One Hundred Years of Statistical Mechanics", he argued that the field was initiated by the 1857 paper of Rudolf Clausius on "The Kind of Motion We Call Heat". Admittedly there had been a good deal of activity since Newton, but activity is not the same as progress.

Montroll's thesis had the powerful backing of Willard Gibbs, who wrote in an obituary tribute to Clausius:

> The origin of the kinetic theory of gases is lost in remote antiquity and its completion the most sanguine cannot hope to see. But a single generation has seen it advance from the stage of vague surmises to an extensive and well established body of doctrine. This is mainly the work of three men, Clausius, Maxwell, and Boltzmann of whom Clausius was the earliest in the field and has been called by Maxwell the principal founder of the science. We may regard his 1857 paper as marking his definite entry into this field, although many points were incidentally discussed in earlier papers.

Stephen Brush argues that it is the task of the historian of science to record activity as well as progress, to make sure that false starts and dead ends are given proper coverage as well as the dramatic and exciting successes. Therefore, in addition to describing the fundamental contributions of Clausius, Maxwell, Boltzmann and Gibbs, who laid the foundations of modern statistical physics, he also tells us in detail of the struggles of earlier pioneers such as Boyle, Newton, and Daniel Bernoulli, and of the unsuccessful wave theory of heat which was an attempt to emulate the triumphant wave theory of light.

Maxwell was the first to appreciate that the language of probability and statistics is essential in relating the behaviour of a macroscopic body to the properties of its microscopic constituents. Boltzmann developed and extended Maxwell's ideas and introduced his famous hypothesis relating the entropy of a macrostate to the combinatorial weight of microstates. He also pursued the kinetics of the approach to equilibrium, and was forced to grapple with the irreversibility paradox — how it is possible for equations of motion, which are reversible on the microscopic scale, to give rise to irreversible macroscopic phenomena. The introduction of these novel ideas and the battle to get them accepted are among the most fascinating stories in the history of physics. Brush considers that these concepts may have helped significantly to bring about the acceptance of probability and indeterminancy in twentieth-century quantum physics.

Statistical mechanics played a central role in leading Planck to his famous quantum hypothesis. However Brush claims that the standard textbook account that the quantum of energy $h\nu$ was introduced to overcome the "ultra-violet catastrophe" is false and was invented by Paul Ehrenfest. Planck was looking for a formula which would fit the theoretical and experimental results on black body radiation. His result did not immediately produce much excitement in the world of physics. Gradually, as a result of Einstein's interpretation of the photoelectric effect, experimental developments in spectroscopy, and the success of Bohr's model of the atom in interpreting some of them, his new hypothesis gained acceptance.

A substantial part of the book is devoted to the history of modern fields of research, and here the author faces the difficult problem of coping with a burgeoning yet scattered literature. Many important results are first published in conference proceedings, and reliable guidance can be obtained only by consulting active researchers. Professor Brush has adopted this method, and has incidentally reproduced many interesting personal anecdotes.

The coverage given to different contemporary topics is subjective. The superfluidity of liquid helium receives exhaustive treatment, presumably because the author himself was actively engaged in the field. More space is devoted to this topic than to the whole of phase transitions and critical phenomena, each success or failure of the "collective excitation" approach of Landau and the rival "Bose Einstein condensation" of London and Tisza being faithfully recorded. By contrast the theory of superconductivity receives quite cursory treatment.

It is inevitable in a book covering such a wide variety of topics that there should be some omissions. For example, in the area of phase transitions (with which I myself have been concerned) the treatment of the solid–liquid transition makes no reference to the important work of Sir Francis Simon and his collaborators on the melting curve at high pressures. The concepts of scaling and universality which play such an important part in the modern theory of critical phenomena are not given proper attention. There is no account of the return to Landau's ideas in their Landau–Ginzburg form for the development of the renormalization group. The work of Patashinskii and Pokrovski in the Soviet Union should also be mentioned. In the classical period no reference is given to the work of Ornstein and Zernicke who provided the first correct description of correlations near the critical point; and Andrews's Bakerian Lecture to the Royal Society in 1869 deserves to be included in the

reference list. All these points might perhaps be taken into account in a second edition.

One of the tasks of the historian of science is to see that credit is properly assigned for scientific discoveries. Professor Brush emphasizes the part played by Wilhelm Lenz, the supervisor of Ernst Ising, in formulating the Ising model; in fact Brush uses the terminology "Lenz–Ising model". He also tells the sad story of J.J. Waterston who anticipated some of the ideas of Clausius in 1845. Waterston's paper was rejected by the Royal Society and the manuscript was not even returned to the author. In addition, the respective contributions of Bose and Einstein to the development of Bose–Einstein statistics, and of Fermi and Dirac to Fermi–Dirac statistics are described.

A useful feature of the book is the wide and detailed reference list, and research scientists will be surprised to find how the literature on the history of science has grown. For example, I learnt of the existence of English translations of several of Clausius's fundamental papers, and of a publication of Waterston's collected scientific papers. In all, this is a book from which all who are interested in statistical mechanics can benefit. □

Cyril Domb is Professor of Physics at Bar-Ilan University, Ramat-Gan, Israel.

Managing disease

J.W. Deacon

The Nature and Practice of Biological Control of Plant Pathogens.
By R. James Cook and Kenneth F. Baker.
American Phytopathological Society: 1983. Pp.539. $43.

BIOLOGICAL control of plant diseases has generated much interest in recent years, in large part because of the efforts of a few workers such as James Cook and Kenneth Baker. The achievements up to 1974 were summarized and discussed in their earlier book, *Biological Control of Plant Pathogens*; this new work is a companion volume rather than a replacement, special attention being given to developments in the past decade. The book is impressive: quite simply, there has never been a better exposition of the "ecological" approach to plant disease control. The authors draw upon their first-hand experience and wide knowledge, and the result is an authoritative and highly readable account of the subject. It should be welcomed by both specialists and university students in the plant sciences.

The title, however, is surely misleading. In the view of many people, biological control is brought about by a third party (i.e. not by the host or the pathogen), either applied directly or promoted by manipulating other factors. Instead, the authors have defined biological control so broadly that it leads to near-absurdities, for example when we are told (p.391) that the growing of genetically different crop cultivars in neighbouring areas is a form of biological control because it restricts the spread of pathogen races specific to any one cultivar. Further (p.407), the use of lime and inorganic fertilizers are said to be ways to achieve biological control if they affect plant resistance. The term then loses all useful meaning.

Semantics apart, this book is actually about *disease management* by manipulating the host, pathogen or environment (including microorganisms) to achieve what the authors term "sustainable agriculture". As such, it is timely and thought-provoking, though it could usefully have included chemical control methods, because a sustainable agriculture must harness, rationally, all available resources for plant protection. Let us hope that plant pathologists will follow the entomologists' lead in this respect.

Returning to biological control in a restricted sense, there are several successful techniques that are applied widely in commercial practice. But all too many of the "successes" discussed in this book have never reached the stage of exploitation, and the authors could have been more critical in this respect. For example, their earlier book cited astounding benefits when *Bacillus subtilis* was applied to seeds of crops in Australia: in field trials, carrot yields were increased by 48% and oat yields by 40%, even when the untreated crops showed no obvious disease symptoms. Baker was associated with this work, so now we could expect to learn of further developments. Instead, the earlier reports are merely repeated. Why aren't Australian growers using *B.subtilis* and getting huge yield increases? Was the work abandoned or were subsequent trials inconclusive? In order to justify its title, the book should have addressed such questions. And why cite yet more "successes" in the use of seed-applied microbes to control damping-off diseases? We knew this in the 1950s and there have been regular reports ever since, but the method has not been adopted commercially because we have cheap, dependable and reasonably safe fungicides that give the necessary short-term protection to seedlings.

In short, biological control will achieve more converts if it is *seen* to be approached with realism and less of an evangelical spirit. But this is a relatively minor point. Cook and Baker's new book will encourage and assist workers in this field, while helping to ensure that the momentum of work on biological control is sustained. □

J.W. Deacon is a Lecturer in Microbiology at the University of Edinburgh, currently working at the Citrus and Subtropical Fruit Research Institute, Nelspruit, South Africa.

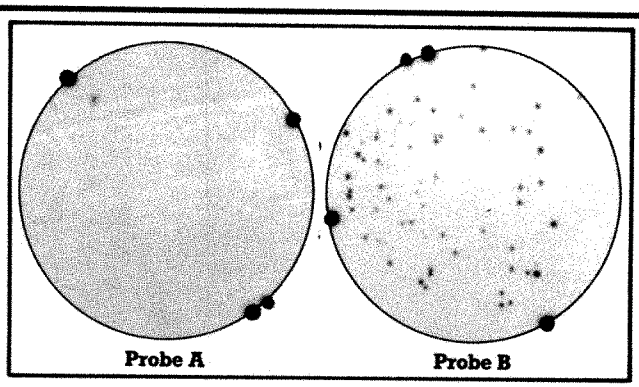
Clearly intermediate mechanics

J.W. Humberston

Theoretical Mechanics.
By E. Neal Moore.
Wiley: 1983. Pp.456.
£28.10, $37.90.

THERE are already so many books on classical mechanics, that one might well question the need for yet another — the field is not growing in the sense that fundamentally new material is continually being added to it. *Theoretical Mechanics* deserves attention, however, because the style of presentation and the philosophy behind it are somewhat unusual.

The book is designed for students who are already familiar with the subject matter covered in the usual undergraduate course in basic mechanics and who wish to have an introduction to more advanced topics such as Hamiltonian and Lagrangian mechanics, variational methods and canonical transformations. The author believes that an initial understanding of these topics is more likely to be acquired by practice in solving problems than by studying the formal structure of the subject. Accordingly, he has provided numerous worked examples and sets of problems at the end of each chapter.



The book begins with a brief review of basic Newtonian mechanics, and, in addition to the topics already mentioned, contains chapters on central force motion, rotations, oscillations and stability, and a brief introduction to the special and general theories of relativity. Several of these topics are treated in more elementary books on mechanics, but the presentation here is usually more advanced; for example, the Runge – Lenz vector is introduced in the discussion of the motion of a particle under an inverse square law of force.

Eighty pages are devoted to several mathematical appendices, some of which are rather inappropriate in a book at this level. So while the appendices on tensors and group theory are useful, it hardly seems necessary to give the elementary properties of vector operations, determinants and matrices. Finally, there is a quite comprehensive bibliography and a list of references to articles on mechanics published in the *American Journal of Physics*.

The book is well produced, contains very few typographical errors and is written in a pleasantly informal style. But, as the author himself admits in the preface, rigour is often sacrificed in the interests of clarity. □

J.W. Humberston is a Lecturer in the Department of Physics and Astronomy at University College London.

Precision Probes from Celltech

Probe A 3′-T T G G T C A T G C **T** A C T C-5′
Probe B 3′-T T G G T C A T G C **C** A C T C-5′

Chymosin A 5′-A A C C A G T A C G **A** T G A G T T T-3′
3′-T T G G T C A T G C T A C T C A A A-5′

Chymosin B 5′-A A C C A G T A C G **G** T G A G T T T-3′
3′-T T G G T C A T G C C A C T C A A A-5′

The illustration shows nitrocellulose colony hybridisations of bacterial colonies containing plasmids with inserts coding for chymosin B. These have been probed with oligonucleotides specific for chymosin A on the left and chymosin B on the right. These oligonucleotides differ by only a single base.

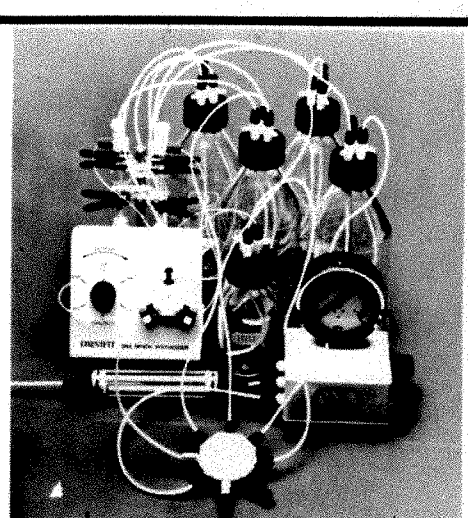
NEW! Manual DNA Synthesis Kit

- Easy-to-use
- High speed chemistry
- Makes up to *four* 20-mers
- Inexpensive



Catalog number: NU-6092

The Biosearch Kit utilizes a modified phosphate-triester synthesis method that features 20 minute cycle times and excellent reagent stability! Short cycle times make this kit less tiring to use than other kits and enables the user to make more than one oligomer in a day. The kit contains a supply of reagents sufficient to synthesize four 20-mers, a complete set of instructions, a description of the chemistry, and purification and characterization techniques.

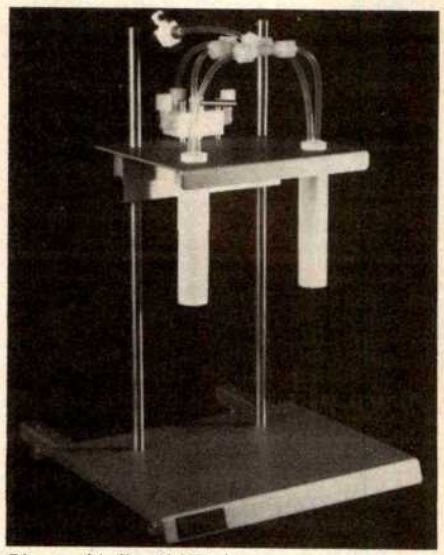
Peptides and oligonucleotides

The field of commercial synthesis and sequencing of peptides and oligonucleotides is booming.

● Biobrene and Bioglobin, manufactured in the United States by Applied Biosystems, are available in the United Kingdom through Biotech Instruments. Biobrene is a specially purified form of polybrene which is widely used in micro-sequencing of proteins and peptides. Biobrene has been especially purified to minimize interference during sequencing. This is important in the interpretation of HPLC chromatograms, particularly in the micro-sequencing of small amounts of protein. Bioglobin is sperm whale myoglobin purified specifically for use as reference compound in protein sequencing work. Applied Biosystems can also perform custom synthesis of peptides up to 25 amino acids in length.
Circle No. 100 on Reader Service Card.

● New from Cruachem Inc. of Oregon is a low-cost semi-automated DNA synthesizer. In the new instrument, wash and deprotection cycles are handled automatically so that the only manual operation required during the synthesis is the injection of monomers in the appropriate order at the start of each cycle. Using this instrument, an operator can produce up to two 16-mers in an eight hour day while being present for a total of only 30 minutes. The use of Cruachem "One-Shot" packs, pre-dried and pre-weighed monomers, adds simplicity while guaranteeing fresh reagents every cycle.
Circle No. 101 on Reader Service Card.

● The Industrial Microbiology division of Celltech operates a custom synthesis service for oligonucleotides. A new price list has just been published and copies are available either through *Nature*'s Reader Enquiry Service or direct from Celltech.
Circle No. 102 on Reader Service Card.



● Bio-Rad's "Gene Machine" is a new approach to preparative gel electrophoresis for recovering nucleic acids from agarose gels. The Gene Machine, using a circular gel format, can electrophorese large sample volumes into concentric bands which are then discontinuously eluted from a circular collection chamber in the centre of the electrophoresis cell. The operator need only cast the gel and add buffer and sample. The control unit will automatically cycle electrophoresis, elution, and sample collection. Up to 10 mg of DNA or 50 mg of RNA can be fractionated in 24 to 48 hours. Greater than 80% recoveries can be obtained with DNA fragments ranging in molecular weight from 0.1 to 16×10^6.
Circle No. 103 on Reader Service Card.

● A range of functionalized controlled-pore glass support materials for oligonucleotide synthesis is available from Cruachem. The materials have proved successful in rapid oligonucleotide synthesis by the phosphotriester method. The controlled-pore glass supports offer high flow rates and good dimensional stability in continuous-flow systems. Several options of nucleotide loading and linker type are offered, and residual silanol functionality has been blocked by silylation before derivatization.
Circle No. 104 on Reader Service Card.

● Custom DNA and peptide synthesis is now available from Biosearch Inc. of San Rafael, California. Further "custom" services are custom liquid hydrogen fluoride cleavage and a protein deglycosylation service. For users' own laboratories, Biosearch produces a liquid hydrogen fluoride cleavage apparatus and a manual DNA synthesis kit.
Circle No. 105 on Reader Service Card.

The "Gene Machine" from Bio-Rad

Biosearch's liquid HF cleavage apparatus.

● Completely purified, ready-to-use DNA fragments of 1.0 A_{260} units (or more) can be obtained from OCS Laboratories of Denton, Texas. Two-week delivery is promised in the United States and discounts are available on larger orders.

Master polyacrylamide gel electrophoresis.

You don't need to be a polymer chemist to master polyacrylamide gel electrophoresis (PAGE). At least not if you have Bio-Rad's new Technical Bulletin 1156, "Acrylamide Polymerization—A Practical Approach." It includes page after page of useful information on such topics as · critical parameters · polymerization protocols · polymerization analysis · handling of gel reagents. Also a section on troubleshooting! With this document to help, the novice can master PAGE and the experienced user can optimize separations even further.

The Applied Biosystems 430A peptide synthesizer

● The Applied Biosystems Model 430A peptide synthesizer is designed for fully automated peptide synthesis. The Model 430A features a novel pre-activation system which converts each amino acid to a very efficient reacting species immediately before each coupling step. The synthesizer has a defined protocol optimized for each amino acid and can also be fully programmed by the user for straightforward adaptation to other chemistries. This combination of a pre-activation system and flexible programming allows experienced peptide chemists to easily implement a variety of automated chemistry modifications and synthesis alternatives.
Circle No.107 on Reader Service Card.

● The new Bachem UK office, in Saffron Walden, Essex, is able to provide a confidential custom synthesis service for peptides, carried out by the company's staff in the United States. The company offers a free analysis service to confirm the purity of products. Analysis is carried out using high-pressure liquid chromatography, fast atom bombardment mass spectrometry, and nuclear magnetic resonance techniques. In addition, Bachem has recently developed a range of products for oligonucleotide synthesis, including a low-cost DNA synethesizer, and also offers oligonucleotide custom synthesis.
Circle No.108 on Reader Service Card.

● The CRB Pepsynthesizer is the first peptide synthesizer incorporating the simplicity and high efficiency of the Fmoc-polyamide solid phase method with the speed, economy and ease of operation of a continuous flow system. This low cost, bench top instrument uses a simple, rapid procedure producing projects of high purity and yield. Use of the Fmoc-Polyamide method avoids the repetitive and vigorous acid treatments required in conventional synthesis and considerably reduces the accumulation of byproducts.
Circle No.109 on Reader Service Card.

● System 990 is the latest peptide synthesizer from Beckman Instruments, Inc.. A new brochure is now available covering the solid phase synthesis technique and the various metholologies that can be accommodated. It also describes the new integral microprocessor controller with cassette loader. For a copy of the new brochure (Bulletin SB-387C) contact the Spinco Division of Beckman Instruments or use *Nature*'s Reader Service Card.
Circle No.110 on Reader Service Card.

● Cruachem has developed a new microcomputer controlled DNA synthesis module which automates solvent and reagent delivery in chemical synthesis of oligonucleotides. The new system achieves maximum flexibility, and allows use of both phosphotriester and phosphoramidite synthetic protocols. Control software is available for the Apple II-plus Apple II-E and Apple II-C microcomputers, and for a BBC Model B microcomputer.
Circle No.111 on Reader Service Card.

● Two new DNA sequencing systems from American Bionuclear are designed to provide "no-problem" electrophoresis. The SQU-1000 (20 cm width) and the SQU-2000 (33 cm width) are fully adjustable to provide the flexibility of running sequencing gels from 20 cm to 1 m in length. A wide range of accessories is available, including sawtooth and standard combs, aluminium cooling plates, spacer sets from 0.2 to 0.5 mm in thickness, and glass plates from 20 to 100 cm in height. The EPS-4000 power supply is capable of running two DNA sequencing gels simultaneously. Also from American Bionuclear, the EPS-4000 provides 200-watts at up to 4,000V.
Circle No.112 on Reader Service Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Service Card bound inside the journal.

Multiply cell yield in your suspension cell cultures

with Techne "Double Helix" Stirring Systems

The Techne Stirring System levitates cells in a steady stream upwards around the axis of the flask and causes them to descend outwards to the center of the bottom surface. It is called the Thomson flow pattern. We call it the "Techne Double Helix" since the motion consists of ascending and descending helices. Our system is unique* and unobtainable in conventional spinner flasks. This gentle circulation of the medium optimizes cell growth and is excellent for difficult-to-grow cells, hybridomas and monoclonal antibodies.

For full details, call or write for Catalog 203.

C P SNOW – THE PHYSICISTS

A GENERATION THAT CHANGED THE WORLD

'A layman can understand the complexities of a beautiful and terrible science.' *Daily Express*

'compulsive reading . . .' *Spectator*

C P Snow's last book takes the layman into the remote world of top-level science. From the 'Golden Age' of physics before World War II to the splitting of Uranium 235, the Manhattan project and, finally, Hiroshima, he brings to life the personalities and politics behind some of the cataclysmic events of this century. Brilliant and informed text illustrated with contemporary photographs throughout.

UNIVERSITY OF OXFORD

DEPARTMENT OF BIOCHEMISTRY

MRC IMMUNOCHEMISTRY UNIT

RESEARCH ASSISTANT -1B

(ref: B/R/107)

Applications for this 3 year appointment are invited from graduates in biochemistry, or molecular biology, to work on the primary structures of complement receptors and related proteins.

Salary on the scale £6,745 — £8,530 pa depending on age, experience and qualifications.

Applications including curriculum vitae and the names and addresses of two referees, should be sent to: The Administrator, Department of Biochemistry, South Parks Road, Oxford, OX1 3QU not later than July 20th, 1984. (2936)A

AGRICULTURAL AND FOOD RESEARCH COUNCIL INSTITUTE OF ANIMAL PHYSIOLOGY

Babraham, Cambridge, CB2 4AT

SCIENTIFIC OFFICER

Required in the Immunology Department to work with Dr Bruce Roser on the regulation of the immune response to transplantation antigens. The work will involve some minor small animal surgery, cell transfer, cell separation and identification techniques (including fluorescent antibody methods and FACS 420 analysis), and in vitro techniques including monoclonal antibody production and screening.

Previous experience should preferably include at least one of these techniques. Applicants should have a degree, or equivalent, in immunology, physiology, biochemistry or cell biology. Salary scale (under review): £5,682 x 6 increments to £7,765. This post is supported by a five year grant from the MRC, and will subsist whilst funds are available. In accordance with the provisions of the Employment Protection (Consolidation) Act 1978, staff on short-term appointments are required to waive any statutory right to redundancy payments, or to make claims of unfair dismissal in respect of termination of appointment on the due date.

For an application form, please write to the Institute Secretary, quoting Ref: BR5, by 2 July 1984.

The AFRC and the grant-aided institutes of the AFRS are Equal Opportunities Employers. (2958)A

ROCKEFELLER UNIVERSITY

CELL BIOLOGIST

CENTER FOR BIOMEDICAL RESEARCH

Wanted to perform independent research as part of a group of biochemists, molecular biologists, and cell biologists interested in the general area of hormone action and male reproduction. Tissue culture experience and 2 to 4 years of postdoctoral training preferred. Excellent support available, MD, DVM, PhD, or equivalent postdoctoral degree.

Salary will depend on qualifications and experience. Send résumés to: Dr Wayne Bardin, The Population Council, Center for Biomedical Research, Tower Building, 1230 York Avenue, New York, New York 10021. An Equal Opportunity Employer. (NW622)A

LOTHIAN HEALTH BOARD

TEMPORARY PART-TIME BASIC GRADE CYTOGENETICIST

(24 hours per week) based at the Cytogenetics Laboratory, Department of Pathology, Royal Hospital for Sick Children, Edinburgh required immediately until 20th January, 1985 during the absence of a member of staff on maternity leave.

Experience in human genetics is essential.

Further information from Miss P M Ellis, Cytogenetics Laboratory, Royal Hospital for Sick Children, Edinburgh, telephone 031-667 1991 ext 272.

Typewritten applications, giving particulars of age, qualifications and previous experience, together with the names and addresses of two referees should reach the Area Personnel Officer, 11 Drumsheugh Gardens, Edinburgh EH3 7QQ by 30th June, 1984. Quote M/83. (2979)A

YORK UNIVERSITY

DEPARTMENT OF BIOLOGY

Applications are invited for

RESEARCH ASSOCIATE AND TECHNICIAN POSITIONS

Projects centre on the mechanisms of DNA repair and mutagenesis and involve the cloning and sequencing of mutant bacterial and mammalian genes. Interests also include how mutations alter gene expression and molecular evolution. In accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada.

Applications are also invited for post-doctoral appointments for up to three years following graduation.

Letters of application including curriculum vitae and three letters of reference should be sent to Dr B W Glickman, Biology Department, York University, Toronto, Ontario, Canada M3J 1P3. (NW613)A

Veterinary Clinician

We have a vacancy in the Veterinary Clinical Unit of our Safety of Medicines Department for a research orientated Veterinary Graduate. The unit is involved in the clinical monitoring and interpretation of the results obtained during the safety evaluation of novel pharmaceutically active compounds.

This position provides an interesting and challenging opportunity to become involved in the development of specialised techniques in ophthalmology and electrophysiology and you would be encouraged to play an active part in directly relevant clinical research. The unit includes veterinary and science graduates who liaise with staff in a variety of disciplines, including toxicology and pathology, in the design of studies.

Previous experience in practice or research work would be an advantage although full training will be provided and more recently qualified graduates are encouraged to apply.

In return we can offer you a very competitive salary package together with excellent technical facilities and modern working conditions. Relocation assistance will be provided if appropriate.

The Division's research laboratories are situated in pleasant parkland surroundings in rural Cheshire yet within easy reach of main road and rail routes.

If you are interested in using your clinical skills in a stimulating and successful environment please reply including a detailed c.v. to:

ICI

Mr R Yates (ICP 860),
Personnel Officer,
ICI Pharmaceuticals Division,
Mereside, Alderley Park,
Macclesfield, Cheshire. SK10 4TG. (2984)A

NEW ZEALAND DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH

Director

N.Z. GEOLOGICAL SURVEY

N.Z. Geological Survey, with a staff of 143 including 87 scientists, is a Division of DSIR based at Lower Hutt, 15 km from Wellington, and with District and Project Offices at both the North and South Islands. Its activities range from mapping, through paleontology and petrology to petroleum, coal, engineering geology and earth deformation studies. It collaborates closely with other DSIR Divisions, eg. Geophysics Division and is linked to the DSIR computer network.

Applications are invited from geologists with sound research experience and recent, relevant administrative experience — preferably in a scientific institutuion.

Salary: A salary of between NZ$40,059 and $51,601 pa is offered depending on qualifications and experience.

(Application instructions below).

Director

GEOPHYSICS DIVISION

The Division has wide geophysical interests throughout New Zealand and the S.W. Pacific, particularly those stemming from the boundary between the Indian and Pacific plates (eg. seismicity, volcanism and earth deformation). It also carries out marine surveys and exploration directed towards assessment of economic resources (eg, geothermal energy, coal, water). The division has a staff of 76 of which half are professional scientists. The headquarters are in Wellington with sub-stations at Lower Hutt and Wairakei and the division is also concerned with geophysical observations at Apia Observatory (Western Samoa) and in Antarctica.

Applications are invited from scientists with relevant research experience and preferably possessing administrative experience in a scientific area.

Salary: A salary of between NZ$37,896 and $49,141 pa is offered depending on qualifications and experience.

Applications forms etc. are available from the Immigration Department, New Zealand High Commission, New Zealand House, Haymarket, London SW1Y 4TQ.

Applicants should quote Vacancy No. 3309 Imm 2/335/55 for Geological Survey position and Vacancy No. 3310 Imm 2/335/56 for Geophysics position.

Closing date for applications: 2nd August, 1984.

(W1074)A

THE UNIVERSITY OF CAMBRIDGE THE BIOTECHNOLOGY CENTRE

The Biotechnology Centre at Cambridge has been established to foster closer links with industry, to achieve a two-way technology transfer and to train high quality graduates from both the physical and biological sciences. The Biotechnology Centre is engaged in a vigorous and innovative programme of fundamental and applied research in several areas including downstream processing, biosensors and bioelectronics and immobilised biocatalysts. In support of this strategy, the Centre expects shortly to be in a position to make the following appointments to develop new downstream processing technologies for the purification of the blood coagulation factor VIII to therapeutic quality.

Postdoctoral Research Associate

Graduate Research Assistant

The projects entail the development of simplified assay systems for factor VIII and the synthesis of novel affinity ligands and their exploitation in solid and liquid phase affinity process technologies for the large scale purification of human factor VIII. The posts are part of a 5 year programme of joint research with the Blood Products Laboratory, Elstree. Applicants should ideally have some experience in blood or protein fractionation although some training in clotting factor assays will be available at BPL.

Initial salaries will be £7,190 — £8,530 p.a. for the postdoctoral research associate and £5,880 p.a. for the graduate research assistant with annual increments according to National Scales 1A and 1B respectively.

Potential applicants should send a curriculum vitae detailing relevant experience and the names and addresses of two referees to Dr C R Lowe, The Biotechnology Centre, Downing Street, Cambridge CB2 3EF, UK by July 6th, 1984. Previous applicants need not apply.

(2960)A

Exciting research opportunity in West Germany; Partake in studies on intracellular metabolism and ion movements in organelles and intact cells

Ideal candidate must have a PhD (junior faculty) and should have experience in high resolution NMR technology (^{31}P, ^{23}Na) and its application to complex biological systems. A Bruker multinuclear NMR instrument (AM 400 widebore) is expected to be intstalled by the end of June 1984. In addition to the researcher's salary, this federally funded position includes salary for one technician, start-up funds and an appropriate supply budget. The research laboratories are part of the Max-Planck-Institut fuer Systemphysiologie in Dortmund, West Germany. Starting date: August, 1984.

Please send CV and references to Dr. Rolf Kinne, Director, Max-Planck-Institut fuer Systemphysiologie, Rheinlanddamm 201, 4600 Dortmund 1, West-Germany.

(W1047)A

NATIONAL INSTITUTE FOR HIGHER EDUCATION DUBLIN

Applications are invited for a:-

LECTURESHIP IN CHEMICAL SCIENCES

The School of Chemical Sciences is centrally involved in the BSc degree course in Analytical Science, in addition to servicing other courses, and possesses a comprehensive range of modern analytical instrumentation. The appointed candidate will become involved in the implementation and further development of teaching programmes and will be expected to initiate and develop programmes of research and to become involved in expanding links with industry.

Applicants should have interests in one or more of the following areas:

Analytical Science (instrumental aspects, inorganic analysis, separations science),

Applied Chemistry (areas of applied inorganic, organic or physical chemistry).

Applicants should be well-qualified academically with appropriate research, teaching or industrial experience.

Salary Scale: Lecturer IR£13,797 - IR£18,807
Assistant Lecturer IR£10,727 - IR£13,218

Application forms, and further details, are available from the Personnel Office, National Institute for Higher Education, Glasnevin, Dublin 9, Ireland. Closing date: 3 August 1984.

(2875)A

UNIVERSITY OF EAST ANGLIA
Norwich

SENIOR RESEARCH ASSOCIATE

Applications are invited for a one-year appointment in the Climatic Research Unit to work on a project investigating climatic change over the past century. The successful candidate will have considerable computing experience and a strong background in meterology and/or climatology. A doctorate in an appropriate discipline, a capability for innovative statistical analysis, and experience in report writing are required. The salary will be on the scale £7,190 to £11,615 per annum (under review).

A starting date no later than October 1st 1984 is desired. Applications should be sent, preferably by August 15th, to the Director, Climatic Research Unit, University of East Anglia, Norwich, NR4 7TJ, from whom further particulars of the appointment are available. (2962)A

UNIVERSITY OF STIRLING

CHAIR IN PSYCHOLOGY

Applications are invited from suitably qualified persons in Psychology and related disciplines without any restriction on the applicant's field of interest. Salary within the professorial range.

Further particulars are available from the Secretary, University of Stirling, Stirling FK9 4LA; Tel: 0786 73171, Ext 2250, to whom applications should be sent by 30 September 1984. (2953)A

M.R.C. Clinical Research Centre
(Northwick Park Hospital)
Watford Road,
Harrow, Middlesex HA1 3UJ.

Technician in Electron Microscopy

A vacancy exists for a Technician to work in the well equipped section of Electron Microscopy at the Clinical Research Centre. The successful applicant will be required to work on a variety of research projects, particularly involving the application of immunolabelling techniques, including low temperature embedding methods and immunogold labelling. Previous experience is required and the ability to carry out the general care of Philips 300 Microscopes would be an advantage.

Minimum qualifications are an HNC or science degree in an appropriate subject with a salary within the range £6,114-£8,370 depending on age and experience.

Application forms and further details may be obtained by writing to Miss J. Cottam, Personnel Section, Quoting ref 112/2/4133.

Closing date: 13th July, 1984.

HEAD PROTEIN PURIFICATION PILOT

Toulouse Labege Centre — Elf Bio Recherches, a specialist in biotechnology based at Toulouse Labege, its new research centre, is strengthening its research teams, and is recruiting its head of protein purification pilot plant. This person will be responsible for transferring laboratory protocols and developing pre-industrial purification systems in order to obtain products for pharmaceutical use. He will be responsible for a team of research scientists and technicians. The successful applicant will have been trained to a high level in biochemistry and chemical engineering (PhD or equivalent) and will be able to prove several years of experience in pre-industrial and/or industrial purification.

For this position, please write to Mr. Fabre, quoting the reference B/T2008N.

71 bis, allées Jean Jaurès —
31000 TOULOUSE — FRANCE

RESEARCH POSTS IN

Medicinal Chemistry
Cellular Electrophysiology
Neuroimmunology
Neuropharmacology

Applications are invited for positions at Senior Scientist level, tenable from 1 January 1985.

The Institute will be housed in well-equipped and spacious new laboratory accommodation which is being built within the precincts of University College London, with which strong academic links will be forged. The scientific staff will be built up to 25–30 by 1987.

The Institute will embark on a programme of basic research in neurobiology, concentrating initially on mechanisms involved in nociception, with the long-term aim of developing new compounds of potential therapeutic value. Initially there will be six laboratory groups (Medicinal Chemistry, Biochemistry, Neuropharmacology, Cell Biology and Cell Culture, Immunology, Cellular Electrophysiology) which will collaborate on a range of individual projects.

Applicants for these positions should be 28–35 years old, with at least two years' post-doctoral experience. The research programme of the Institute will be interdisciplinary in its approach, and an ability to contribute original ideas and to collaborate effectively are particularly important.

Medicinal Chemistry

For this position a good knowledge of synthetic organic chemistry and an enthusiasm for active collaboration with biologists in the design and testing of new compounds are essential. Experience of working in the pharmaceutical industry would be an advantage.

Cellular Electrophysiology

This post will require the application of electrophysiological methods to the analysis of drug action at the cellular level. Candidates should have considerable experience of micro-electrode recording techniques or *in vitro* preparations, preferably with experience of patch-clamping.

Neuroimmunology

This post will entail the applications of immunological methods to the study of neurones in culture and *in situ*, as a means of investigating neuropeptides surface antigens and receptors. Previous experience in this area is less important than a strong background in biochemistry, cell biology and immunology, and an innovative approach to research.

Neuropharmacology

Expertise in electrophysiological recording methods *in vivo* and *in vitro* is required. The work will involve studying the effects of drugs on activity in specific sensory pathways in the peripheral and central nervous system.

Salary negotiable around £15,000 p.a. according to experience and assistance with relocation costs available if relevant.

Applications by 16 July 1984, including c.v. and names of two referees, to Professor H.P. Rang, FRS, Director, Sandoz Institute for Medical Research, Department of Pharmacology, University College London, Gower Street, London WC1E 6BT (Tel: 01-388 5314), from whom further information can be obtained.

(2898)A

SANDOZ

Department of Veterinary Pathology, University of Edinburgh and the Moredun Research Institute, Gilmerton Road, Edinburgh.

Applications are invited for the following appointments to an A.F.R.C. Linked Research Group between the Departments of Veterinary Pathology, University of Edinburgh and the Moredun Research Institute, Animal Diseases Research Association, Edinburgh. The appointments are for five years.

The research programme is concerned with fundamental studies of the sheep immune system in relation to disease mdoels of persistent viral infections of sheep. The posts are located within the University Department but there will be frequent interaction with the Institute as dictated by the research programme. The appointees will work with experienced research workers in immunology and virology.

Appointments:

Research Fellow 1A — Postdoctoral cellular immunologist for studies on the in vitro analysis of lymphocyte and accessory cell function and immune regulation in vivo within lymphoid tissue (Ref. LRG31/1). Salary £8,080 — £9,875.

Research Fellow 1A — Postdoctoral immunochemist/biochemist for biochemical characterisation of lymphocytes and accessory cell membrane glycoproteins, biochemical aspects of antigen presentation using viral polypeptides (Ref. LRG31/2). Salary £8,080 — £9,875.

Research Technician — (TG4/5) with experience in cellular immunology for studies on lymphoid cell function and monoclonal antibody work. Salary on range £5,826 — £6,898 (under review) with placement according to experience and qualifications. (Ref. LRG31/3).

Research Technician — (TG4/5) with experience of biochemistry for immunochemical work on cellular and viral antigens. Salary on range £5,826 — £6,898 (under review) with placement according to experience and qualifications. (Ref. LRG31/4).

Technical Assistant — (TG2) for general laboratory duties connected with the above research programme. Salary £4,662 — £5,151. (Ref. LRG31/5).

All appointments carry full superannuation and National Insurance benefits.

Applications (curriculum vitaes, 2 referees) for posts LRG31/1 and LRG31/2 should be sent to the Secretary to the University, Old College, South Bridge, Edinburgh, from whom further particulars can be obtained. Applications for posts LRG31/3, 4 and 5 should be sent to the Personnel Office, 63 South Bridge, Edinburgh. Informal enquiries can be made to Professor I. McConnell, Department of Veterinary Pathology, Royal (Dick) School of Veterinary Studies, Summerhall, Edinburgh. Tel 031-667 1011 ext 5322. Closing date for applications 6th July 1984. (2910)A

MAITRE DE CONFERENCE/ASSOCIATE PROFESSOR OF ANIMAL PHYSIOLOGY, UNIVERSITE DE PAU — FRANCE

PhD degree in nutrition or in sensory physiology required. Duties: teaching in French language of undergraduate general biology students; active participation in experimental ecology research: relations between legumes and animals (particularly insects) in a new CNRS-University Institute. Salary range of MC1 (88,560 FF) to MC3 (126,000 FF), will be on a 1-year renewable basis.

Application including curriculum vitae should be sent before 1st July 1984 to Pr. V. LABEYRIE, IBEAS, Université de Pau, Casino Municipal, 64000 PAU, France. (W1046)A

SUNDERLAND POLYTECHNIC

Faculty of Science
BIOLOGY DEPARTMENT

Research Assistant in Microbial Technology

Salary scale: £4,947-£5,649 (under review)

Applicants should hold a first or second class honours degree in a relevant biological science. The successful candidate will be expected to register for a higher degree and will work with a research group involving staff at Sunderland and Teesside Polytechnics and at Newcastle University. The project will be concerned with developing techniques for the immobilisation of carbon monoxide-oxidising bacteria.

Application forms and further details are available from the Personnel Officer, Sunderland Polytechnic, Langham Tower, Ryhope Road, Sunderland, SR2 7EE, or telephone (0783) 76231 Extn. 11.

Closing date: 11 July, 1984. (2941)A

FACULTY POSITION IN PHARMACOLOGY

Applications are invited for a tenure track appointment as an Assistant or Associate Professor in the Department of Pharmacology at the University of Tennessee Center for the Health Sciences. Applicants as Assistant Professor should possess the Ph.D., M.D., or other doctoral degree, have at least 2 years of postdoctoral experience, and have demonstrated ability to conduct an independent research program which applies modern constructs and methods of biochemistry, molecular biology, immunology, or genetics, to research problems in Neurosciences as applied to Pharmacology. Responsibilities include the development of an independent research program, and participation in the Pharmacology Department teaching programs.

Applicants as an Associate Professor should have 5 years of experience and an established externally supported research program. Please forward curriculum vitae, a research proposal, and arrange three letters of reference to be sent to Dr Murray Heimberg, Chairman, Department of Pharmacology, University of Tennessee Center for the Health Sciences, 874 Union Avenue, Memphis, TN 38163. Inquiries should be received prior to July 15, 1984, for a position available immediately. UTCHS is an equal opportunity/affirmative action employer. (NW624)A

UNIVERSITY OF ST ANDREWS

DEPARTMENT OF PHYSIOLOGY + PHARMACOLOGY

TEMPORARY LECTURESHIP IN PHYSIOLOGY & PHARMACOLOGY

Tenable for three years from 1 October 1984. Preference will be given to candidates with an interest in the fields of muscle physiology, neurobiology or membrane physiology.

Salary at appropriate point within range £7,190 to £8,530 per annum (under review), plus USS.

Further particulars may be obtained from the Establishments Officer, The University, College Gate, St Andrews, Fife KY16 9AJ, to whom applications (two copies preferably in typescript) with the names of three referees, should be sent to arrive not later than 16 July 1984. (2968)A

LEICESTER POLYTECHNIC

SCHOOL OF CHEMISTRY

PHYSICAL CHEMISTRY LABORATORY TECHNICIAN

Scale 4/5 Salary
£6,264 — £7,896.

The postholder will be solely responsible for the day-to-day running of a Physical Chemistry teaching laboratory. The successful applicant will be likely to hold an HNC or equivalent qualification, have some experience of laboratory organisation and be competent in the routine maintenance of laboratory equipment. He or she would be expected to participate in the work of the laboratory and collaborate with other members of the technical and academic staff.

Further information may be obtained from Dr C Groves on ext 2368.

Application forms from the Personnel Office, Leicester Polytechnic, PO Box 143, Leicester LE1 9BH. Tel (0533) 551551 Ext. 2303. (2939)A

UNIVERSITY OF LEICESTER

DEPARTMENT OF PHYSIOLOGY

GRADUATE RESEARCH ASSISTANT

Ionic Channels in Muscle

Applications are invited for the above post to work with Dr N B Standen and Dr P R Stanfield on a 3 year project supported by the MRC involving patch-clamp studies of skeletal muscle fibres. In addition to single channel recording from adult and cultured cells, carried out on-line to a computer, methods for channel reconstitution and their study in lipid bilayers will be used. The successful applicant will be expected to register for a PhD degree. Commencing 1 October, 1984.

Salary on scale £6,310 — £7,190.

Applications including the names of two referees to Dr P R Stanfield, Department of Physiology, University of Leicester, Leicester LE1 7RH, who will be pleased to supply further information. Closing date, Monday 16 July, 1984. (2930)A

KING'S COLLEGE LONDON

DEPARTMENT OF PHARMACOLOGY

RESEARCH TECHNICIAN

Applications are invited for the above position to assist in a project concerning the modification of lipoproteins by arterial wall cells and its relationship to atherosclerosis. The post is for 3 years initially and is available immediately. It is funded by a Medical Research Council Grant awarded to Dr David S Leake.

Qualifications: BSc, HNC, or equivalent in Pharmacology, Biochemistry or related discipline. Experience in tissue culture would be an advantage, but not essential as training will be given.

Initial salary (according to experience) £6,146 pa or £6,401 pa (incl) rising to £6,689 pa (incl) (under review). 5 weeks annual holiday. Superannuation Scheme.

Apply in writing, with CV including 2 referees, to: The Assistant Secretary Personnel (ref: 249025) King's College, Strand, WC2R 2LS. (2931)A

UNIVERSITY OF STRATHCLYDE

DEPARTMENT OF PHARMACY

(PHARMACEUTICAL CHEMISTRY) UGC "New Blood" LECTURESHIP IN PHYTOCHEMISTRY

Applications are invited from candidates under 35 years of age who do not hold a tenured post in a UK university for a "New Blood" Lectureship in Phytochemistry. Candidates should hold a first degree in Pharmacy, Chemistry or relevant Biological Science and have completed a higher degree in some aspect of Phytochemistry. The successful candidate will be expected to participate in the present research activities of the Phytochemistry Group, to initiate novel research in Phytochemistry and to teach relevant chemical courses leading to BSc(Hons) Pharmacy and MSc degrees. Preference will be given to candidates with particular interests in structural elucidation, quantitative analysis or biological function of natural products.
Salary for the post will be on the Lecturer scale £7,190 — £14,125 per annum. USS benefit.
Further particulars and application forms (please quote ref: 34/84) are available from Staff Office, McCance Building, 16 Richmond Street, Glasgow G1 1XQ. Closing date for applications: 12 July 1984. (2925)A

UNIVERSITY OF LEICESTER

DEPARTMENT OF MICROBIOLOGY

RESEARCH TECHNICIAN

Applications are invited for a three-year MRC-funded appointment to commence 1st August 1984. The successful candidate will join a research group working on the pathogenicity of polio and related picornaviruses and will be encouraged to take an active interest in the scientific background of the project. The work will involve the use of a range of recombinant DNA and cell culture techniques.

For appropriately qualified candidates the appointment will be on the Technician Grade 3 Scale (£5,151 — £6,035).

Applications, including a curriculum vitae and the names of two referees should be sent to Dr J W Almond, Department of Microbiology, University of Leicester, University Road, Leicester LE1 7RH. (2918)A

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF MEDICAL CELL BIOLOGY

TECHNICIAN GRADE 3

Required immediately to assist project to study non-muscle cell motility. Work is concerned with the molecular mechanisms of control of actin filament assembly and reorganisation in cells.

Candidates must possess ONC or appropriate equivalent in a Biological discipline plus three years relevant experience. Post suitable for candidates holding degree in Biochemistry or related discipline in which Biochemistry constituted a significant part.

Post available for three years.

Initial salary within range £5,151 — £5,439 per annum. (Under Review)

Application forms may be obtained from The Registrar, The University, P O Box 147, Liverpool, L69 3BX. Quote Ref: RV/546/N (2937)A

UNIVERSITY OF BRISTOL

'NEW BLOOD LECTURESHIP'

Applications are invited for the post of Lecturer in Physics in the general area of liquid state physics with an interest in the interplay between statistical mechanical theory and experiment. Experience in some aspect of experimental liquid state physics or computer simulation would be an advantage but is not essential. The successful candidate will, however, be expected to be associated with the work of Professor J E Enderby or Dr R E Evans. Salary will be on the Lecturers' salary scale (£7,190 — £14,125), under review.

Further particulars should be obtained from the Registrar and Secretary, University of Bristol, Senate House, Bristol BS8 1TH, to whom applications should be sent by 6th July 1984, quoting reference JC. (2922)A

UNIVERSITY OF BIRMINGHAM FIELD ARCHAEOLOGICAL UNIT

DEPARTMENT OF CHEMISTRY

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the above post to work on a project on decay and detection on archaeological sites.

A strong chemistry background is necessary and the ideal candidate should have a higher degree in the area of soil chemistry with an interest in Microbiology.

Post is tenable for up to three years from 1 July 1984. Salary on the Research Fellow 1A scale £7,190 — £11,615 plus superannuation.

For further particulars phone 021-472-1301 ext 2559, quoting reference F4.

No formal application form. Three copies of application, including full curriculum vitae and naming three referees to Assistant Registrar, (Science and Engineering), P O Box 363, Birmingham B15 2TT by 6 July 1984. (2948)A

CSIRO

AUSTRALIA

SOIL BIOLOGIST/ ROOT PATHOLOGIST

$A25,342-$A31,270

DIVISION OF SOILS GLEN OSMOND SA

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The **CSIRO** Division of Soils is a member of the Institute of Biological Resources.

FIELD: Soil Biology/Root Disease

GENERAL: The Division of Soils studies the physics, chemistry and biology of soils and other porous media, together with the integrative disciplines of pedology and geomorphology. It also seeks to establish principles for the application of soil science to agriculture, forestry, hydrology, engineering and conservation. The Division has laboratories in Adelaide, Brisbane, Canberra and Townsville.

The research associated with this position is funded by the South Australian State Barley and Wheat Industry Research Committees for a period of 3 years.

Field research by the Division of Soils indicates that *Rhizoctonia solani* is a serious pathogen of cereals and grain legumes in southern Australia following a change in management systems involving reduced cultivation and trash retention. Before practical control of this disease can be achieved it will be necessary to gain a greater understanding of the ecology and epidemiology of this pathogen under different soil and field conditions. The ultimate aim of this project is to develop methods of controlling the disease in the field by a variety of techniques, eg. cultivation, chemical and biological control, weed control and the screening of resistant varieties.

DUTIES: As a member of a team, conduct research on the effects of soil, tillage and rotation on root diseases of wheat on a range of soils with different rainfalls. The current program encompasses studies in the laboratory, controlled environment cabinets, glass house and in the field.

QUALIFICATIONS: A PhD degree or equivalent qualifications majoring in biological sciences or agricultural science. Relevant postgraduate experience is essential, together with expertise in root pathology and field experimentation on soil-borne root diseases.

TENURE: A term of three years. Australian Government superannuation benefits are available.

APPLICATIONS: Quoting reference No M8040, should be directed to:

The Chief
CSIRO Division of Soils
Private Bag No 2
GLEN OSMOND SA 5064
AUSTRALIA

By July 20, 1984.

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER

(W1063)A

QUEEN MARY COLLEGE University of London

Research Opportunities in Geomaterials

POSTDOCTORAL RESEARCH ASSISTANTSHIP: This SERC-funded post is to continue and further develop a major project concerned with the durability and performance of rock rubble mound breakwaters. The research involves field, laboratory and computer studies of armouring materials. Appointment for 2 years with initial salary in range (under review) £8,376 — £9,716 pa (including London Allowance).

SERC/ CASE RESEARCH STUDENTSHIP: This PhD Studentship is to continue researches concerned with deterioration and cracking of concretes due to alkali-aggregate reactivity. The work will be carried out in association with consultant engineers Mott Hay and Anderson.

Applications from suitably qualified graduates in geology, engineering geology, geochemistry or related sciences should apply by letter, with cv and names of 2 referees, to The Senior Personnel Officer, Queen Mary College, Mile End Road, London E1 4NS, by 2 July. (2978)A

The European Molecular Biology Laboratory,
a research institute situated in Heidelberg, West Germany,
invites applicants for the following vacancy

TECHNICAL ASSISTANT

The successful candidate will join a group working in the area of nucleic acid and peptide synthesis and in the development of instrumentation in these areas.

Applicants should possess a degree or equivalent qualification in chemistry and should have a strong background in organic chemistry. Technicians with an interest in biochemistry, molecular biology or physical organic chemistry are especially invited to apply. The working language will be English or German.

An above average salary will be offered to the successful candidate. Certain allowances are payable in addition, depending on personal circumstances. An initial contract of 3 year's duration which can be renewed, will be offered.

Please write briefly for an application form, quoting ref. N° 84/29 to : EMBL, Personnel Section, Postfach 10.2209, D-6900 Heidelberg (W1066)A

MRC BRAIN METABOLISM UNIT
Edinburgh
Organic Chemist

The MRC Brain Metabolism Unit invites applications from suitably qualified chemists for the post of Organic Chemist with special expertise in the synthesis of neuropeptides and appropriate analogues. Candidates of immediate post-doctoral or equivalent status will be preferred. A period (minimum 3 months) of training in the peptide chemistry in the laboratory of Dr R.C. Sheppard (MRC Laboratory of Molecular Biology) may be offered to a suitable candidate who, although highly competent in organic chemistry, has no special expertise in peptide chemistry.

The person appointed will work in close association with the Molecular Biologists in the Unit who are interested in the mechanisms of synthesis, release and mechanism of action of neuropeptides in mammalian brain. The appointment will be short-term (3 years). Remuneration will be at an appropriate point on the scales for university non-clinical academic staff.

Further details can be obtained from the Director, Dr G. Fink, MRC Brain Metabolism Unit, Department of Pharmacology, 1 George Square, Edinburgh EH8 9JZ. Four copies of applications and the names and addresses of three referees to be sent to Mrs A. Milligan, Administrative Officer, MRC Brain Metabolism Unit, Department of Pharmacology, 1 George Square, Edinburgh EH8 9JZ by Friday, July 27. (2917)A

PLANT BREEDING INSTITUTE
Maris Lane, Trumpington, Cambridge CB2 2LQ
A Post Doctoral Fellow

Sponsored by Ciba Geigy Corporation for a period three years, is required to initiate a research programme aimed at isolating transposable DNA elements from potato, in collaboration with Dr M D Bevan and Mr R E Gunn of the Institute. Emphasis will be placed on analysing changes in gene structure caused by somaclonal variation; practical experience in recombinant DNA techniques is essential and experience or an interest in mobile DNA elements would be advantageous.

Candidates should have a first or upper second class honours degree in an appropriate biological subject with at least 2 years experience in biochemistry/molecular biology or related research, and a PhD.

Appointment will be as Higher Scientific Officer (£7,149-£9,561 pa). Pay award pending. Non-contributory pension scheme.

Applications with curriculum vitae and names and addresses of three referees should be sent to the Establishment Officer, quoting reference CYT/ 182, by 19 July 1984.

The Institute is an Equal Opportunities Employer. (2959)A

THE ANIMAL VIRUS RESEARCH INSTITUTE
HEAD OF IMMUNOLOGY AND PATHOLOGY

Applications are invited for a new post of Head of the Division of Immunology and Pathology, the appointment to commence 1 October, 1984.

Candidates should have a high academic research record in molecular or cellular immunology, with experience, or an interest in, the immunology of virus infection in farm animals, and proven skills of leadership.

The Division includes Departments of immunology, experimental pathology and vaccine research and the successful candidate would also become head of the Immunology Department.

Salary in scale LSTG 16,343-LSTG 20,794 (Grade 6 previously known as Senior Principal Scientific Officer). Sick leave and non-contributory superannuation schemes. 25 days annual holiday. House may be available for suitable married applicant.

Further information, and application forms from the Secretary, Animal Virus Research Institute, Pirbright, Woking, Surrey GU24 0NF. Tel: 0483-232441. Closing date for applications 10th July, 1984. (2967)A

AGRICULTURAL AND FOOD RESEARCH COUNCIL
Institute of Animal Physiology, Babraham, Cambridge CB2 4AT
TEMPORARY MOLECULAR BIOLOGIST

Applications are invited from molecular biologists to work on the regulation of the synthesis of polypeptide factors and hormones involved in the control of animal growth and reproduction. Candidates should have postdoctoral experience of mRNA isolation and in vitro translation, cDNA synthesis and gene cloning in eukaryotic systems. Details may be obtained from K D Brown or A P F Flint (Tel: Cambridge (0223) 832312). The appointment will be at Higher Scientific Officer (£7,149 — £9,561) or Senior Scientific Officer (£8,970 — £11,476) level depending on qualifications and experience and will be for 2 years. In accordance with the provisions of the Employment Protection (Consolidation) Act 1978, staff on short-term appointments are required to waive any statutory rights to redundancy payments or to make claims of unfair dismissal, in respect of termination on the due date. Applications should be sent to the Institute Secretary, AFRC Institute of Animal Physiology, Babraham, Cambridge CB2 4AT, before 9 July 1984.

The AFRC is an Equal Opportunities Employer. (2927)A

UNIVERSITY OF LEICESTER
DEPARTMENT OF BIOCHEMISTRY
POST-DOCTORAL RESEARCH ASSOCIATE

Applications are invited for a post-doctoral position to work on the mechanisms of transformation of animal cells in culture by Rous sarcoma virus (RSV). The work will initially be directed towards clarification of the relationship between tyrosine-specific phosphorylation of the cytoskeletal protein vinculin by $pp60^{v}$-src (the transforming gene product of RSV), and other aspects of the transformed phenotype. The work may also involve analysis of the structure of vinculin and the vinculin gene.

Applicants should have a PhD in Biochemistry, and experience in some area of Tumour Biology is desirable.

Salary within the range £7,190 to £8,975.

The position is available immediately, although the starting date is negotiable, and will be for 2 years.

Applications (together with the names of two referees) should be sent to Dr D R Critchley, Department of Biochemistry, University of Leicester, University Road, Leicester LE1 7RN. (2919)A

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF GEOLOGY
DEMONSTRATOR/ SENIOR DEMONSTRATOR

Applications are invited for a Demonstrator/Senior Demonstrator in sedimentary geology in the Department of Geology. Duties include laboratory demonstrating in a wide range of undergraduate courses in sedimentology and palaeontology, field work instruction and tutorials in general geology. The successful candidate may also be required to lecture in Honours classes on specialist topics related to his/her research interests. The demonstrator will also be expected to contribute to the research activities of the department by developing his/her research interests and by interacting with staff members and post-graduate students.

Candidates should have completed, or virtually completed, their Ph.D. and be prepared to commence the position on October 1st. The appointment is for a fixed term of up to three years.

Initial salary within the range £6,310 — £8,530 per annum.

Applications (three copies), together with the names of three referees, should be received not later than 6 July, 1984 by The Registrar, The University, P O Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/545/N (2905)A

THE ANIMAL VIRUS RESEARCH INSTITUTE

HEAD OF MOLECULAR BIOLOGY

Applications are invited for a new post of Head of the Division of Molecular Biology, the appointment to commence 1 October 1984. The successful candidate would also become head of the Department of Biochemistry, and would lead a vigorous team investigating the biochemistry and genetics of several important exotic animal diseases including foot-and-mouth disease, bluetongue, and African swine fever viruses.

Candidates should have a high academic research record in the molecular biology of viruses and proven skills of leadership.

Salary in scale of lstg 16,343-lstg 20,794 (grade 6 previously known as Senior Principal Scientific Officer). Sick leave and non-contributory superannuation schemes. 25 day annual holiday. House may be available for suitable married applicant.

Further information and application forms from the Secretary, Animal Virus Research Institute, Pirbright, Woking, Surrey GU24 0NF. Tel: 0483 232441. Closing date for applications 10th July 1984. (2966)A

UNIVERSITY OF QUEENSLAND
Brisbane, Australia

PROFESSOR OF ORGANIC CHEMISTRY

Applications are invited for the Chair of Organic Chemistry. Applicants should be able to present evidence of substantial research achievement in the field of organic chemistry. The successful applicant will be expected to demonstrate and encourage excellence in research, and will be given responsibilities by the Head of the Chemistry Department for undergraduate and postgraduate teaching in the Organic Section of the Department.

Salary per annum: $A51,006. Closing date: 31 July 1984.

Please supply names of three referees.

LECTURER/ SENIOR LECTURER IN ZOOLOGY (Tenurable)

Higher degree in biology and demonstrated expertise and teaching experience in biostatistics required. Teaching and research experience in ecology or animal behaviour desirable.

Salaries per annum: Senior Lecturer $A32,677 — $A38,085, Lecturer $A24,353 — $A31,994. Closing date: 31 August 1984.

Additional information and application forms are available from the Staff Officer, University of Queensland, St Lucia, Qld 4067, Australia, or from the Secretary General, Assocation of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (W1071)A

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF BIOCHEMISTRY

RESEARCH ASSISTANT

Applications are invited for a Research Assistantship to work with Dr N J Russell on the mechanism of membrane changes in moderately halophilic bacteria during adaptation to altered salinity. The work will involve membrane and lipid isolation/characterisation, radiochemical enzyme assays and TLC/GLC analysis. Candidates should have graduated in biochemistry, microbiology or a closely related subject.

The appointment, which is for three years, is funded by a grant from the Science and Engineering Research Council, and there will be some collaboration with the University of Ottawa. Salary RA range 1B £6,310 — £7,190 per annum. Duties to commence 1st September, 1984.

Applications (2 copies), including a curriculum vitae, together with the names and addresses of two referees, should be sent to the Establishment Officer, University College, P O Box 78, Cardiff CF1 1XL. Closing date 16th July, 1984. Ref: 2794. (2921)A

THAMES POLYTECHNIC
SCHOOL OF BIOLOGICAL SCIENCES AND ENVIRONMENTAL HEALTH

LECTURESHIPS IN BIOTECHNOLOGY

SL IN MICROBIAL GENETICS

LII IN BIOLOGICAL CHEMISTRY

Applications are invited for the above posts from appropriately qualified graduates. Experience in one or more of the following is essential: molecular/microbial genetics; microbial physiology/biochemistry; fermentation technology; natural product chemistry, enzyme/cell technology.

Salary scale: £8,202 — £12,555 inclusive (under review).

SERC RESEARCH STUDENTSHIP

Applications are invited for a SERC research studentship from 1 October 1984 on a project from: biochemistry of bacterial lipopolysaccharides; molecular biology of wood-rotting fungi/lignin degradation; insect neurobiology. Applicants should have, or expect to obtain, a good honours degree in biology or related discipline. Please indicate choice of project.

Further particulars and application form from the Staffing Officer, Thames Polytechnic, Wellington Street, London SE18 6PF, to be returned by 3 July 1984.

Thames Polytechnic is an equal opportunities employer. (2915)A

CSIRO

AUSTRALIA
RESEARCH SCIENTIST/ SENIOR RESEARCH SCIENTIST
$A25,342 — $A37,274
DIVISION OF PLANT INDUSTRY
CANBERRA ACT

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Plant Industry is a member of the Institute of Biological Resources.
FIELD: Biochemistry
GENERAL: The Division conducts research fundamental to plant biology and applies its results to agricultural problems. Current research in its Biochemistry Section includes studies on chloroplast membranes, protein and nucleic acid metabolism in chloroplasts, photosynthetic carbon metabolism, the biochemistry of seed proteins, and haemoproteins involved in nitrogen fixation.
DUTIES: To conduct a program of research directed towards developing herbicides selectively effective against C_4 plants based on knowledge of biochemical processes specific to C_4 photosynthesis. The successful applicant will be expected to conduct research to expand the range of biochemical targets currently being examined, to supervise the day to day conduct of the biological screening procedures, and to co-operate with organic chemists in decisions about the direction of the synthetic program.
QUALIFICATIONS: A PhD degree or equivalent qualifications with research experience in the areas of enzymology, enzyme kinetics and structure-biological function relationships. A strong background in organic chemistry is desirable.
TENURE: Indefinite with Australian Government superannuation benefits available.
APPLICATIONS: Stating full personal and professional details with the names of at least two referees and quoting reference No A4726, should be directed to:

The Chief
CSIRO Division of Plant Industry
GPO Box 1600

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER (W1064)A

PLANT MOLECULAR GENETICIST

Applications are invited for a faculty position at the Assistant or Associate Professor level in the Department of Vegetable Crops, University of California, Davis. We are seeking a Molecular Geneticist to address important problems in higher plant biology. Potential research areas might include gene expression, genome organization or gene transfer. The appointee will exploit the extensive tomato genetic resources available in the department and will be expected to contribute to the campus-wide program in molecular biology. This position is an 11-month, tenure track appointment with commitments of 15% and 85% research. Qualifications include a Ph.D. in genetics, molecular biology, or other closely allied discipline with training in molecular genetic techniques. Teaching and advising responsibilities will be within the appointee's area of specialization. Training of graduate students will be a significant responsibility.

Applicants should submit a curriculum vitae with a bibliography, reprints of pertinent publications, a statement of research and teaching interests, transcripts, and the names and addresses of at least three referees to: Dr. D. J. Nevins, Chair, Department of Vegetable Crops, University of California, Davis, California, 95616. Application deadline is September 30, 1984. Position available, December 1, 1984.

The University of California is an Affirmative Action/Equal Opportunity Employer. (NW614)A

CELLULAR BIOCHEMISTS

IMMUNEX, a Seattle based biotechnology company, is presently expanding its Cellular Biochemistry Department. The interests of this group center around the biochemical characterization of lymphokines, the development of rapid, sensitive and quantitative biological or biochemical assays for lymphokine detection, and assessment of the cellular mechanisms through which lymphokines act to stimulate or suppress cellular responses.

We are seeking candidates with a Ph.D. in Biochemistry or Cell Biology who have an interest in immune regulation and whose research training lends itself to the above goals. Training in immunology is not a prerequisite, but candidates must possess generic biochemical skills of a high order.

Immunex's multidisciplinary approach, coupled with a collegial scientific atmosphere, provides an excellent research environment. Our salaries are competitive and the benefits package includes equity participation opportunities. Please send resumes to:

Personnel Director
Immunex Corporation
51 University St.
Seattle, WA 98101 (NW619)A

immunex

UNIVERSITY OF CAMBRIDGE

PLANT BREEDING

Applications are invited for a University Demonstratorship in the Department of Applied Biology, to teach an area of Plant Breeding at undergraduate and graduate level, and engage in research, in a field other than molecular genetics. Candidates should have appropriate Honours degree and post-graduate research experience.

Further particulars may be obtained from the Administration Secretary, Department of Applied Biology, Pembroke St., Cambridge CB2 3DX (2955)A

WASHINGTON STATE UNIVERSITY

RESEARCH COORDINATOR

PhD in biochemistry or related areas to provide day-to-day guidance to a research group composed of postdocs, graduate students and technicians working on enzymology and molecular biology related to lipids and other natural products under the direction of P E Kolattukudy.

Send, by August 15, 1984, a complete CV and references to Director, Institute of Biological Chemistry, Washington State University, Pullman, WA 99164-6340. WSU is an Affirmative Action/Equal Opportunity employer. (NW618)A

PLANT BREEDING INSTITUTE
Maris Lane, Trumpington, Cambridge CB2 2LQ

Plant Molecular Biologist

A post-doctoral position, sponsored by Shell Research Limited for three years, is required to investigate the control of gene expression. The work will involve the dissection of functional regions of plant genes under hormonal control and their reintroduction into chromosomal DNA in modified form.

Candidates should have a first or upper second class honours degree in an appropriate biological science with at least 2 years experience in biochemistry/molecular bilogy or related research, and a PhD.

The appointment will be as Higher Scientific Officer (£7,149 – £9,561 pa). Pay award pending. Non-contributory pension scheme.

Applications with curriculum vitae and names and addresses of three referees should be sent to the Establishment Officer quoting reference CYT/ 178 by 19th July, 1984.

The Institute is an Equal Opportunities Employer. (2883)A

JAMES COOK UNIVERSITY OF NORTH QUEENSLAND

TEMPORARY LECTURER IN BIOCHEMISTRY

Applications are invited from candidates from any area of Biochemistry for appointment as Temporary Lecturer in the Department of Chemistry and Biochemistry. The position is available from January 1985 to 31 December 1986.

Applicants must have a higher degree in Biochemistry. The appointee will be engaged in teaching, research and associated duties.

The salary range for the position is $A24,353 – $A31,994 per annum and commencing salary will be determined in accordance with qualifications and experience.

Further information and application forms are available from The Registrar, James Cook University, Townsville, Qld, 4811, Australia, with whom applications close on July 20, 1984. In reply please quote Reference No. 84085. (W1062)

POSTDOCTORAL POSITIONS

YEAST AND BACILLUS

Two positions available immediately. One for studies of the expression and replication of the virus-like dsRNA Killer plasmids of S. cerevisiae. Major focus on modifications of killer cDNA's to test effects on expression and secretion of proteins. The other for studies of the cloning and expression of spo genes in B. subtilis expressed uniquely in one of the two cell compartments present late in sporulation. DNA cloning experience desirable. Salary commensurate with experience.

Send C.V. and names of 3 references to: Dr Donald J Tipper, Department of Molecular Genetics and Microbiology, University of Massachusetts Medical School, 55 Lake Avenue North, Worcester, MA 01605, USA. (NW610)A

LOTHIAN HEALTH BOARD

TEMPORARY PART-TIME BASIC GRADE CYTOGENETICIST

(24 hours per week) based at the Cytogenetics Laboratory, Department of Pathology, Royal Hospital for Sick Children, Edinburgh required immediately until 20 January, 1985 during the absence of a member of staff on maternity leave.

Experince in human genetics is essential.

Further information from Miss P M Ellis, Cytogenetics Laboratory, Royal Hosptial for Sick Children, Edinburgh, telephone 031-667-1991 extension 272.

Typewritten applications, giving particulars of age, qualifications and previous experience, together with the names and addresses of two referees should reach the Area Personnel Officer, 11 Drumsheugh Gardens, Edinburgh, EG3 7QQ by 30 June, 1984. Quote M/83. (2973)A

MICHIGAN STATE UNIVERSITY

POSTDOCTORAL RESEARCH ASSOCIATE

(Biochemical Toxicology)

One Research Associate position is available immediately on an NIH sponsored three year project to study effects of xenobiotics on plasma membrane receptors, cellular calcium regulation, sodium and chloride channels, protein kinases, and ATPases.

Send Curriculum Vitae and names of three references to: Dr Fumio Matsumura, Pesticide Research Center, Michigan State University, East Lansing, MI 48824.

Michigan State University is an equal opportunity/affirmative action employer. (NW617)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
UNIVERSITY OF LONDON

DEPARTMENT OF MEDICINE

POSTDOCTORAL RESEARCH ASSISTANT

Required for up to 3 years to work with Dr Gregory Gregoriadis on a project supported by the MRC on the use of liposomes as immunological adjuvants in vaccines. Strong background in immunology an advantage/experience of liposome technology is not required.

Salary on Research Range 1A.

Applications by full curriculum vitae, quoting the names and addresses of two referees should be submitted to the School Office, RFHSM, Rowland Hill Street, London NW3 2PF. Further details available on request (telephone 01-794-0500 Extn. 4262). Closing date 13 July 1984. Please quote reference RA/GG/2. (2902)A

UNIVERSITY OF BIRMINGHAM FACULTY OF ARTS

CHAIR AND HEADSHIP OF THE DEPARTMENT OF PHYSICAL EDUCATION AND SPORTS SCIENCE

Applications are invited for the Chair and Headship of the Department of Physical Education and Sports Science which is now vacant. Applicants should have active academic interests in at least one of the Department's areas of study and research, and be willing to strengthen or establish links with other departments.

Salary in the professional range, plus superannuation.

Further particulars available from the Vice-Chancellor, University of Birmingham, P O Box 363, Birmingham B15 2TT, to whom applications (15 copies: 1 from overseas applicants) should be sent by 1st September 1984. (2928)A

UNIVERSITY OF BRISTOL

DEPARTMENT OF MATHEMATICS

Applications are invited for a

LECTURESHIP IN NUMERICAL ANALYSIS

Applicants should have a good research record and be likely to interact with present members of the Department. The salary scale for lecturers is £7,190 — £14,125 (under review) and initial salary will be determined according to age, qualifications and experience. The post is tenable from 1st October 1984 or a mutually agreeable date.

Further particulars should be obtained from the Registrar and Secretary, University of Bristol, Senate House, Bristol BS8 1TH, by whom applications should be received before 25th August 1984, quoting reference JC. (2923)A

UNIVERSITY OF NOTTINGHAM

CELL BIOLOGIST

Applications are invited for the position of Experimental Officer to join the research group developing monoclonal antibodies. The person appointed will be expect to supervise technical staff engaged in hybridoma research and should have relevant experience in cell biology and preferably immunology.

Salary will be at an appropriate point on the scale £6,310 to £9,875 per annum.

Applications including full curriculum vitae and the names and addresses of two referees should be sent to Professor R W Baldwin, Cancer Research Campaign Laboratories, University of Nottingham, Nottingham NG7 2RD. (2961)A

UNIVERSITY OF WARWICK

DEPARTMENT OF BIOLOGICAL SCIENCES

POSTDOCTORAL RESEARCH FELLOW OR RESEARCH ASSISTANT IN MOLECULAR VIROLOGY

In the Department of Biological Sciences to work on a project funded by the Medical Research Council. The work will be concerned with the application of recombinant DNA techniques to the study of Mammalian reoviruses. Salary will be on the Research 1A Scale: £7,190 — £11,615 pa or the Research 1B Scale: £6,310 to £8,530 pa. The position is available for three years from 1st August 1984.

Further information can be obtained by telephoning Drs M A McCrae or A J Easton on 0203 24011, exts 6024/6079.

Applicants should send a cv with the names and addresses of two referees to the Executive Officer, Department of Biological Sciences, University of Warwick, Coventry, CV4 7AL, quoting reference MAM/AJE/NAR. Closing date 6th July 1984. (2914)A

HOWARD HUGHES MEDICAL INSTITUTE

RESEARCH ASSOCIATE/ POSTDOCTORAL FELLOW

MD or PhD sought for 8/1/84 to participate in studies on the role of insulin receptor tyrosine kinase and regulatory protein phosphorylation in insulin action. Experience preferred in the area of reconstruction of membrane proteins; cell fusion; protein chemistry or immunologic techniques.

CV and 3 references required. Salary $17,000 — $20,000/year, depending on experience.

Contact: J Avruch, Howard Hughes Medical Institute Laboratory, Diabetes Unit, Massachusetts General Hospital, Boston, MA 02114; or call: (617) 726-2874. (NW616)A

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

(University of London)
Keppel Street WC1E 7HT

A POSTOCTORAL RESEARCH FELLOW

is required in the Immunology Unit of the Department of Medical Microbiology for a temporary post, initially for two years, to investigate the role of rheumatoid factors in chronic immune complex disease in mice, and supported by a grant from the Nuffield Foundation. Immunological experience essential. Gross salary, depending on qualifications etc, up to £8,376 (under review). Applications, consisting of full curriculum vitae and naming two professional referees, please, to Dr M E Devey at the School. (2964)A

THE HATFIELD POLYTECHNIC

SCHOOL OF NATURAL SCIENCES

LECTURER II/ SENIOR LECTURER IN PHARMACOLOGY

Applications are invited for the post of lecturer/senior lecturer with effect from 1 September 1984. Applicants should possess a higher degree in pharmacology and preference will be given to candidates with post-doctoral research experience. The successful applicant will be expected to contribute to pharmacology teaching at undergraduate and postgraduate level and will be encouraged to conduct research in a specialist aspect of pharmacology.

Salary: Lecturer II: £7,473 — £11,826. Senior Lecturer: £10,941 — £13,701.

Further particulars and application forms may be obtained from Mr R Anderson, Staffing Officer, The Hatfield Polytechnic, P O Box 109, College Lane, Hatfield, Herts. AL10 9AB. Informal enquiries may be directed to Dr B Hunt, Hatfield 68100, Ext 485. Closing date 17 July 1984. Please quote reference 789. (2932)A

Search And Selection Limited

Management Consultants

HEAD

Pharmacology and Biochemistry

A new Department combining Pharmacology and Biochemistry in associated areas of interest has been created by one of the most successful international research based pharmaceuticals companies — a mature scientist of standing is required as Head of Department; principally to manage the science — especially to inspire, motivate and coordinate the team which is some 40 strong (about equal numbers in each discipline) but also of course with responsibility for the administration intrinsic in running a Department of this size.

Considerable experience in managing other scientists, preferably in the pharmaceuticals industry, is essential and so the appointed candidate is unlikely to be younger than 35, with an established record of successful research; qualified in either Pharmacology or Biochemistry with considerable knowledge of both disciplines, holding a good first degree, and a relevant Ph.D as a prerequisite.

Location is in the south-east of England within easy reach of London. Salary guideline in the middle to later twenties with attractive 'extras' including a car.

Interested scientists are asked to send a full curriculum vitae and publications list to:—

Martin Duchesne
Search And Selection Limited,
Suite 3 Council Hall, Penn Road,
Beaconsfield, Buckinghamshire HP9 2PP.

(2933)A

SQUIBB

R&D DIRECTOR

Japan

Squibb, a major international pharmaceutical company, currently is seeking candidates for the position of R&D Director in its Japanese affiliate with offices in Tokyo. The Director must provide strong intellectual and administrative leadership to a staff of about 50 scientists who have responsibility for the registration in Japan of new human ethical and animal health products. In meeting these responsibilities, the department monitors Japanese regulatory requirements, oversees preclinical and clinical studies conducted in Japan, and prepare the necessary registration documents. Throughout this process, close liaison is maintained with the central research laboratories in the United States.

The successful candidate will have at least 15 years experience in the health care field after receiving an MD or PhD degree (or equivalent) and must be fluent in both Japanese and English.

Interested candidates should send their current resume directly to: **Mrs. Anne V. Corey, International Personnel Director, Squibb Corporation, P.O. Box 4000, Princeton, NJ 08540.** An equal opportunity employer.

(NW577)A

In der Fakultät für Physik der
ALBERT-LUDWIGS-UNIVERSITAT FREIBURG I. BRSG.
ist ein

LEHRSTUHL FÜR EXPERIMENTALPHYSIK (C 4)

(Nachfolge Osberghaus)

wieder zu besetzen.

Gedacht ist an Bewerber aus den Forschungsbereichen Atom- und Molekülphysik und deren Grenzgebieten, wie z.B Quantenoptik, Oberflächenphysik, Anwendungen der Synchrotronstrahlung.

Zusammenarbeit auf bestehenden Arbeitsgebieten (Atom-, Molekül- und Polymerphysik) ist erwünscht.

Volle Beteiligung an der Lehre in der Fakultät und an der akademischen Selbstverwaltung wird verlangt.

Bewerbungen sind bis zum 30.09.1984 zu richten an den.

Dekan der Fakultät für Physik
Hermann-Herder-Straße 3, D 7800 Freiburg i. Brsg.

(W1073)A

McGILL UNIVERSITY

MOLECULAR GENETICS GROUP

The Department of Biochemistry, Faculty of Medicine, McGill University is seeking three or four highly qualified individuals to form a research group with interests in the applications of molecular genetics to medically relevant topics. All positions are tenure track at the level of assistant or associate professor. Candidates should have a minimum of two years postdoctoral experience and demonstrated excellence in the application of recombinant DNA technology to animal cell systems. Each new member is expected to develop a separate, vigorous and competitive research program. Positions will be tenable after April 1, 1985.

Applicants are invited to send a complete curriculum vitae, copies of recent publications and the names of three references to Dr. C.P. Stanners, Department of Biochemistry, McGill University, 3655 Drummond Street, Montreal, Quebec, Canada H3G 1Y6.

In accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada; however others are encouraged to apply. (NW612)A

Chair in Reproduction

Department of Clinical Studies, New Bolton Center
University of Pennsylvania, School of Veterinary Medicine

Both nominations and applications are invited for a newly endowed Chair, The Marion Dill and David George Jones Chair, in Reproduction at the School of Veterinary Medicine, University of Pennsylvania. This initiative represents an intent on the part of the School to build upon its already strong programme in reproduction. The successful applicant will be expected to develop an innovative programme of research in an area which is discernably relevant to the reproductive biology of farm animals. The applicant should also have the experience and interest to develop a role in leadership of the Section of Reproductive Studies at New Bolton Center. A degree in veterinary medicine is desirable but not essential.

New Bolton Center is the rural campus of the School of Veterinary Medicine and is situated 30 miles west of Philadelphia.

Interested individuals should send curriculum vitae, references and a summary of research interests to: Dr Alan M. Kelly, School of Veterinary Medicine, University of Pennsylvania, 3800 Spruce Street, Philadelphia, PA 19104. Closing date for applications is September 30, 1984.

The University of Pennsylvania is an Affirmative Action, Equal Opportunity Employer. (NW609)A

CENTRAL MANCHESTER HEALTH AUTHORITY

SENIOR SCIENTIFIC OFFICER — TISSUE TYPING LABORATORY

HLA serologist to join the North West Regional Tissue Typing Laboratory to provide services for renal transplantation. Candidates should have post-doctoral experience in pre and post transplant immunological monitoring techniques, be prepared to carry out administrative duties in support of the transplant programme. The appointee will be expected to take up duties immediately.

Appointment for this permanent position will be on the Whitley council PTA Senior scale (£9,010 — £11,649).

Applications including a full CV to Dr P A Dyer, Principal Scientific Officer, Tissue Typing Laboratory, Dept. Medical Genetics, St Mary's Hospital, Hathersage Road, Manchester M13 0JH. Closing date: 2 July 1984. (2947)A

M.R.C. Clinical Research Centre
(Northwick Park Hospital)
Watford Road,
Harrow, Middlesex HA1 3UJ

Technician

There is a vacancy for a Technician to work in our Division of Clinical Cell Biology which is concerned with biochemical studies of Gastrointestinal disorders. The work will involve establishing and developing chromoatographic and electrophoretic procedures for the separation and isolation of iron transport and storage proteins. Applicants for this position should have an HNC or science degree in an appropriate subject. Salary on appointment will depend on age and experience and will be within the range £6,114-£8,370 (inclusive of London Weighting).

Application forms and further details may be obtained by writing to Miss J. Cottam, Personnel Section, quoting reference 111/2/4044.

Closing date: 13th July, 1984. (2934)A

MRC BONE RESEARCH LABORATORY, Oxford

POST DOCTORAL RESEARCH FELLOW Grade 1A

To study experimental models of human bone formation with Dr Brian Ashton and Dr Roger Smith. Preference will be given to applicants with a background of cell biology or the synthesis of extracellular matrix.

Salary in the range £7,190 — £8,530. The appointment will be for 2 years from the earliest mutually agreeable date.

Applications should be sent to Dr B.A. Ashton, MRC Bone Research Laboratory, Nuffield Orthopaedic Centre, Oxford OX3 7LD and should include a full cv and the names of two referees. (2908)A

ORGANIC SYNTHESIS DEVELOPMENT RESEARCH LABORATORY

CHEMISTS

To develop and scale up processes for synthesis of peptides. PhD or equivalent (2-5 years' experience), interest and practice in organic synthesis essential. Experience in development and/or peptide chemistry an advantage. Syntex offers competitive salaries and a comprehensive benefits package. Please send résumé and salary requirements to Syntex Corporation, Professional Employment, Dept LK, 3401 Hillview Avenue, Palo Alto, CA 94304. We are an equal opportunity employer. (NW607)A

AGRICULTURAL AND FOOD RESEARCH COUNCIL FOOD RESEARCH INSTITUTE

NUTRITION AND FOOD QUALITY DIVISION

SCIENTIFIC OFFICER

The Food Research Institute has a vacancy for a Scientific Officer to investigate the use of immunological techniques for the measurement of vitamins in foods. The person appointed will be trained in the use of these procedures and be involved in the development of these methods, their validation against currently accepted techniques and their eventual use in nutritional research studies in connection with the nutritional value of the UK diet.

Qualifications: A degree in Biochemistry or a related subject and an interest in immunological assays and their applications.

Salary: (under review) On a scale £5,682 — £7,765. Non-contributory superannuation scheme.

The Agricultural Food Research Council is an Equal Opportunities Employer.

Further particulars and application form from The Secretary, Food Research Institute, Colney Lane, Norwich, NR4 7UA, quoting reference number 84/2. Closing date: 5 July 1984. (2912)A

UMIST

RESEARCH ASSISTANT

Graduate/Post-Doctoral Research Assistant post available for two years for work, using lymphocytes, relating to molecular biological aspects of brain ageing and dementia. Previous experience and qualifications in molecular biology preferred.

Commencing salary will be according to age, qualifications and experience in the range of £6,310 — £7,630 p.a. (under review).

Applications, quoting reference OP/100/AI, including a curriculum vitae and the names of two referees should be sent to Dr R F Itzhaki, Molecular Neurobiology Lab, Dept of Ophthalmic Optics, UMIST, P O Box 88, Manchester M60 1QD.

(2975)A

MORRIS COLLEGE, a private and predominantly-black, four year liberal arts college in Sumter, S.C. is seeking two persons to teach courses. 1) a person to teach courses in general biology, genetics, ecology and other undergraduate biology courses. A PhD in biology is required. Beginning date: January 1, 1985. 2) a person to teach courses in physics with a computer science background general physics and electronic) and physical sciences. A PhD in physics required. Beginning date: August 16, 984. Salary and rank commensurate with qualifications and experience. Submit letter of application, letters of recommendation and academic transcript to: The Personnel Officer, Morris College, Sumter, S.C. 29150. Deadline for accepting applications is uly 20, 1984. An Equal Opportunity/ Affirmative Action Employer.

(NW615)A

UNIVERSITY OF LONDON

INSTITUTE OF PSYCHIATRY

DEPARTMENT OF PSYCHOLOGY

Applications are invited for a LECTURESHIP IN THE DEPARTMENT OF PSYCHOLOGY

The successful candidate will provide a service to Hilda Lewis House, a mental handicap unit based at Bethlem Royal Hospital, that has day, residential and community components. Applicants will also be expected to participate in the teaching of the Department on the M.Phil Clinical Psychology Course and in the supervision of trainees. They must be capable of taking an initiative in developing the clinical and research services of psychologists in this unit. Applicants should possess appropriate postgraduate qualification in clinical psychology and relevant experience is desirable.

Salary in accordance with the University of London Lecturer Scale £7,190 — £14,125 plus London Weighting Allowance.

Application forms and fuller job description obtainable from Anne Stevens, Department of Psychology, De Crespigny Park, London, SE5 8AF, and should be returned by Friday, 13th July, 1984. (Tel: 01-703 5411 Ex. 321). (2913)A

JOHN INNES INSTITUTE

POST DOCTORAL POSITION FOR NUCLEIC ACID CHEMIST OR MOLECULAR BIOLOGIST

Applications are invited for the above two year project funded by the Agricultural Genetics Company Limited. The work will be concerned with the development of probes for plant virus identification.

The appointment will be at Higher Scientific Officer (Salary £7,149 to £9,561 p.a.). Qualifications are a first or upper second class honours degree in chemistry, molecular biology or related subject with at least two years relevant experience.

Applications with curriculum vitae and names and addresses of three referees should be sent to The Secretary, John Innes Institute, Colney Lane, Norwich NR4 7UH by Friday 13 July 1984 quoting reference AGC/1. (2971)A

UNIVERSITY OF BRISTOL

CHAIR IN HISTOPATHOLOGY

The University invites applications for a Chair in Histopathology.

Medically qualified candidates are invited to submit applications by 14th September 1984.

Further particulars of the appointment may be obtained from the Registrar and Secretary, University Senate House, Bristol BS8 1TH.

(2957)A

UNIVERSITY OF EDINBURGH

FACULTY OF VETERINARY MEDICINE

DEPARTMENT OF VETERINARY PATHOLOGY

Applications are invited from veterinary graduates for the post of lecturer in Pathology.

The Department has an integrated approach to research and teaching in all aspects of Pathology (immunology, microbiology, morphological pathology) and has considerable expertise and facilities for work in these areas. The person appointed will be expected to contribute to teaching in pathology, to share the service commitments in diagnostic pathology (including post mortem work) and to undertake further research training in pathology leading to a higher degree (PhD or MRC Path if this has not already been obtained).

The salary scale is £7,190 — £14,125 but initial appointment will not exceed £8,975 with first increment on October 1st 1984.

Six copies of application with the names of 3 referees should be submitted to the Secretary to the University, Old College, South Bridge, Edinburgh from whom further particulars can be obtained. Closing date for applications 13th July, 1984. Please quote Reference No.1140.

(2909)A

ICI

CORPORATE BIOSCIENCE GROUP

PROTEIN BIOCHEMIST/ ENZYMOLOGIST

Applications are invited for a protein biochemist to work in the plant science section of the Corporate Bioscience Group. The successful applicant will join a team investigating aspects of cereal grain growth and will be responsible for initiating a programme to study the developmental control of enzymes of starch deposition in endosperm tissue. He or she will probably have post doctoral experience in plant protein isolation and characterisation and will have demonstrated ability to conduct independent research. His/her expertise will complement existing strengths in plant cell biology, biochemistry and recombinant DNA technology, and an ability to work in a multi-disciplinary environment will be essential.

Applications including a full cv should be directed to Miss E H Lauermann, Personnel Officer, Imperial Chemical Industries PLC PO Box No 11 The Heath, Runcorn, Cheshire. Closing date for applications is July 5th, 1984.

Please do not telephone. Write, including a brief synopsis of poster subject and its scientific relevance. Poster space is limited, so we suggest you act promptly.

(NW468)C

TRANSGENE

TRANSGENE, an independent genetic engineering company, carries out high level research oriented towards applications of medical and industrial importance.

TRANSGENE has an opening for an experienced scientist as

HEAD OF THE FERMENTATION LABORATORY

The work will be devoted to the optimisation of fermentation process involving recombinant strains and/or cell lines.

It will require a strong interface with the research groups within the company as well as a practical understanding of aspects relevant for industrial purposes.

Therefore candidates must possess a strong background in biochemical engineering and a good expertise in fermentation and recovery development covering a range of hosts.

Salaries will be competitive and commensurate with qualification.

Knowledge of French is not necessary.

STRASBOURG is a pleasant historic town, located in the heart of Europe, very close to Germany and Switzerland.

The laboratory is located next to the University campus and enjoys close contacts with well known groups in fundamental research.

For confidential consideration, send a cv, a list of publications and indication of salary requirements to:

Tél: (88) 22 24 90

(W1070)A

MEDICAL RESEARCH COUNCIL

Applications are invited for a short-term non-clinical scientific post in the Clinical and Population Cytogenetics Unit, tenable for 3 years. The appointee will work in a small group studying chromosome and nuclear organization, with special emphasis on relating cytological structure to molecular function. Current areas of interest include the nonhistone protein core evident in dehistonized metaphase chromosomes ('the scaffold') specific DNA protein and protein-protein interactions involved in chromosome structure and chromatin condensation, the possible role of repeated DNA sequences in chromosome organization, and the raising of monoclonal antibodies as probes of nuclear structure.

The Unit is well equipped for most aspects of cell and molecular biology including scanning and transmission electron microscopy, flow cytofluorimetry recombinant DNA technology, immunology, and computing facilities.

The successful candidate will have experience in a relevant field, and will be expected to develop his or her own independent research project within the general areas outlined above, while making use of the wide range of experimental techniques available in the Unit.

Remuneration will be at an appropriate point on the scales for University non-clinical academic staff. Applications with the names and addresses of two referees should be lodged with The Administrator, MRC Clinical and Population Cytogentics Unit, Western General Hospital, Crewe Road, Edinburgh EH4 2XU, by Friday 20th July, 1984. Please quote the reference SCS/ 6/ 84.

(2916)A

THE MAX-PLANCK-INSTITUT FÜR KERNPHYSIK HEIDELBERG

invites applications from

ASTROPHYSICISTS or PLANETARY SCIENTISTS

under 30 years of age for a

POSTDOCTORAL RESEARCH POSITION

in theoretical cosmophysic. The current main areas of interest are interstellar dynamics, in particular the influence of cosmic rays, and the formation of stars and planetary systems. The three-year position is free from Sept. '84. The salary is based on the German civil service scale (approx. DM 40.000.-- annually).

Further details may be obtained from Prof H.J. Völk, MPI für Kernphysik, Tel. (6221) 516355. Please send applications, including a CV and the names of two academic referees, to the PERSONNEL OFFICE at MAX-PLANCK-INSTITUT für KERNPHYSIK, D 6900 Heidelberg 1, Postfach 103 980 before July 15th.

(W1077)A

PROFESSOR

The Center for Research in Veterinary Medicine is seeking a person whose primary research responsibility will be to study the agent-host interaction at the molecular and/or cellular level. The successful candidate will also participate in ongoing research projects and contribute to the training of graduate students.
A PhD degree from a recognized university in an area compatible with the responsibilities outlined above; actively involved in research and at least 3 years of post-doctoral experience in cellular or molecular microbiology. The candidate is expected to possess or to be willing to acquire a working knowledge of French. Preference will be given to Canadian citizens and permanent residents of Canada.
Commensurate with experience and with salary scale prevailing at the Institut Armand-Frappier (University of Quebec).
Please send curriculum vitae, list of publications and 3 letters of recommendation to the address below before August 31st, 1984 to: Institut Armand-Frappier, Service des ressources humaines, 531, boulevard des Prairies, Laval-des-Rapides, Laval, Québec, Canada H7N 4Z8. (NW620)A

SOUTH MANCHESTER HEALTH AUTHORITY
CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE
PATERSON LABORATORIES
DEPARTMENT OF IMMUNOLOGY

A position is available forthwith for a

POST-DOCTORAL ASSISTANT

to study the properties of cloned naturally cytotoxic human peripheral blood lymphocytes. The limited tenure of the appointment (until September 1985) is such that applicants should already have acquired considerable expertise in techniques for the purification, fractionation (including FACS IV experience) and tissue culture of human peripheral blood lymphocytes, and familiarity with the extensive literature on natural killer cells.

Salary will be in the range of £8,080 — £10,710, depending on age and experience.

Interested candidates should send a curriculum vitae immediately to Dr Michael Moore (061-445 8123 ext 416) from whom further particulars may be obtained. (2977)A

UNIVERSITY OF ST ANDREWS
DEPARTMENT OF PHYSIOLOGY & PHARMACOLOGY
TEMPORARY LECTURER

Applications are invited for a Temporary Lectureship (three years). In addition to teaching duties, the successful candidate will be expected to carry out research within the field of "muscle energetics, metabolism and locomotion of Antarctic animals'. This work is supported by an award from the NERC Antartic Research Special Topics Programme to Dr I A Johnston.

Some relevant postdoctoral or equivalent research experience in muscle research is essential. Excellent research facilities and support are available for studies of muscle physiology and biochemistry.

Salary at appropriate point within range £7,190 to £8,530 per annum (under reveiw), plus USS.

Further particulars are available from the Establishments Officer, The University, College Gate, St Andrews, Fife KY16 9AJ, to whom applications (two copies preferably in typescript) with the names of three referees, should be sent to arrive not later than 7 July 1984. (2891)A

KING'S COLLEGE LONDON
DEPARTMENT OF BIOPHYSICS
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited to work with Dr H J Gould on the isolation of human immunoglobulin gene binding proteins and the study of their properties, interactions with specific DNA sequences and function. Relevant experience (eg recombinant DNA technology, DNA cloning in eukaryotic cells, and/or transcription mapping) would be desirable.

The post, which is funded by the Leukemia Research Fund, is tenable for three years, starting as soon as possible after September, 1984. Salary in the range £7,190 — £11,615 plus £1,186 pa London allowance.

Applications, including a curriculum vitae and the names of two referees, should be sent direct to Dr Gould, Department of Biophysics, King's College London, 26-29 Drury Lane, London WC2B 5RL, before July 15. Enquiries from applicants in the US may be made to Dr Gould at the National Institutes of Health, Building 2, Room 301, Bethseda, Md 20205, before the end of June.

(2982)A

THE UNIVERSITY OF MELBOURNE

FOUR RESEARCH POSITIONS IN MOLECULAR BIOLOGY/MOLECULAR GENETICS

at the levels of

Research Fellow Grade 1 (Extendible Tenure)
Research Fellow Grade 2 (Extendible Tenure)
Senior Research Fellow (Extendible Tenure)

in the

Department of Veterinary Preclinical Sciences

Applications are invited from Molecular Biologists/Molecular Geneticists interested in the regulation of eukaryotic genes.

A sponsored Research Agreement allows the expansion of the Molecular Biology Group within the Sheep Biology Unit which comprises scientists working in immunology, embryology and physiology and will provide an excellent environment to achieve the long term goal of isolating regulatory DNA sequences for the genetic manipulation of livestock.

Positions are for 3 years with the possibility of renewal for a further period. Salaries will be in the range of $A20,991-$24,047 per annum for Research Fellow Grade 1, $A24,353-$31,994 per annum for Research Fellow Grade 2 and $32,677-$38,085 per annum for Senior Research Fellow. The level of appointment will depend on qualifications and postdoctoral research experience.

Further printed information regarding details of application procedure and conditions of appointment is available from the Appointments Officer (Academic), University of Melbourne, Parkville, Victoria 3052, Australia, or the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications, in duplicate, including names and addresses of at least three referees and quoting Position No. 260 A206, should be addressed to the Staff Officer, University of Melbourne, and close on 18 July 1984.

The University reserves the right to invite applications for the above positions and not to appoint anyone to each of the positions advertised.

(W1076)A

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL
LONDON

DEPARTMENT OF PHYSIOLOGY

LECTURESHIP

Applications are invited for a lectureship in Physiology. Applicants should have an established record in research and would be expected to develop their own research interests.

The post will be held within the Joint Department of Physiology at University College London and this Medical School, where the post will be based.

Salary, according to age, qualifications and experience, within the range £8,376 — £15,312 inclusive of London Allowance.

Further information may be obtained from Professor J A Stephens, Sherrington School of Physiology, St Thomas's Hospital Medical School, London SE1 7EH tel 01-928 9292 ext 2241/7.

Applications in the form of a curriculum vitae, statement of research interests and the names and addresses of 3 referees should be sent to The Secretary, The Middlesex Hospital Medical School, London W1P 7PN by 19 July 1984. (2369)

THE UNIVERSITY OF MELBOURNE

RESEARCH FELLOW GRADE 1 (EXTENDIBLE TENURE)

in the

DEPARTMENT OF BIOCHEMISTRY

Applications are invited from people with a background in physical chemistry or physical biochemistry for appointment as Research Fellow 1. The work involves the use of photophysical techniques to characterize the dynamics of cytoskeletal networks and to study proximity relationships in biomembranes. The position is sponsored by the Australian Research Grants Scheme and is for 2 years.

Salary up to $A22,213 per annum and in the range of $A20,991 to $A24,047. For further information please contact Dr W H Sawyer, Department of Biochemistry, University of Melbourne, Parkville 3052, Victoria, Australia.

Further printed information regarding details of application procedure and conditions of appointment is available from the Appointments Officer (Academic), University of Melbourne, or from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (W1067)A

INTERNATIONAL CENTER FOR MEDICAL RESEARCH FRANCEVILLE — GABON

with the objective of improving Fecondity (sterility, newborn and infant mortality, mother-child relationships, developmental problems)

RECRUITS

— a PhD, MD, or equivalent, specialist in cellular immunology, with at least 3 years post-doctoral experience in basic research.

— a Technician highly qualified in immunology, specially cellular, to act as assistant to the former. At least 5 years experience in basic research.

SUBJECT: immunology of *Loa loa* filariasis, parasitic disease endemic in West Africa, involving work on cellular mechanisms of the immune response, tests of cellular function, cytotoxicity, tissue culture (including hybridomes), T cell cloning and functional tests.

The C.I.R.M.F., created in 1979, employs 165 people of 7 nationalities. It includes departments of: immunology, biology of reproduction, microbiology, anatomo-pathology and parasitology. It has a clinical lab (17,000 samples/year) and gynecological-clinical facilities (30 beds) at the General Hospital. It possesses the most modern investigation equipment and harbours a Primatology Centre with 225 monkeys of 6 species.

CONDITIONS

— Two-year contract, renewable by mutual agreement, commencing September 1984. Attractive salary, negotiable, depending on qualifications and experience, plus expatriation allowance. Knowledge of French an advantage.

— Sixty day annual leave including family transportation, free housing in a complex with tennis and swimming-pool.

For further information or application, send C.V., list of publications, list of 3 referees, present salary to:

The Director of C.I.R.M.F.
28 boulevard de Grenelle,
75015 PARIS (France).

An interview with candidates under consideration will be held in Europe in July or August.

(W1068)A

University of California Lawrence Berkeley Laboratory Announces an opening 1 January 1985 for Associate Laboratory Director and Head of Nuclear Science Division

The Lawrence Berkeley Laboratory is a multi-purpose research laboratory funded by the Department of Energy. Its Nuclear Science Division conducts a multi-million dollar research program in low, medium and high-energy nuclear physics. The Head of the Division has primary responsibility for the leadership and management of this program under the general direction of the Deputy Director for General Sciences and the Laboratory Director. As an Associate Director of the Laboratory, the incumbent will also participate in formulating the research policy and long-term direction of the Laboratory as a whole. Candidates must have had significant experience as practicing nuclear physicists and be of the general calibre of persons holding senior tenure positions in major research institutions. The successful applicant would be expected to serve as Associate Director and Division Head for an initial term of 3 to 5 years, subject to renewal for further terms by mutual agreement.

The Laboratory is seeking a respected and energetic nuclear physicist willing to play a strong leadership role at a challenging time. Qualifications must be such that it will be natural to consider him or her for a tenured appointment in the Department of Physics on the Berkeley campus of the University of California, as well as at the Laboratory. Interested applicants should submit a curriculum vitae, together with the names of three references to: Dr J.D. Jackson, Chairman, Nuclear Science Search Committee, c/o Employment Office, LAWRENCE BERKELEY LABORATORY, 1 Cyclotron Road, Berkeley, CA94720. Refer to Job A/2947. An Equal Opportunity Employer M/F/H. Deadline for applications: August 31, 1984. (NW594)A

LAWRENCE BERKELEY LABORATORY

FERMENTATION CONSULTANT

We are a rapidly growing biotechnology firm manufacturing and selling enzymes and other process aids to the food and drink industries worldwide. Our manufacturing facilities are located in Western Europe and we are currently engaged in expanding our fermentation capacity substantially. We are seeking the services of an experienced fermentation technologist to act as consultant.

The responsibilities of this consultancy will be two-fold (1) to oversee/advise on the commissioning of our new plant and (2) to contribute technically at the pilot and production scale to the optimisation of microbial (bacterial and fungal) fermentation processes currently under development.

Application and correspondence should be submitted to the undersigned below and will be treated in strictest confidence. Keith Walesby, Bio/ Technology, 4, Little Essex Street, London, UK, WC2R 3LF.

UNIVERSITY OF DUBLIN
Trinity College

Department of Immunology

POST-DOCTORAL RESEARCH FELLOW

Applications are invited for the above post in the Department of Immunology at Trinity College, Dublin. The successful candidate will work on a research project concerned with the immunological aspects of respiratory disease. Experience in immunological technology is desirable, though not essential.

Candidates should submit a full curriculum vitae, together with the names of two referees, to:

Dr Conleth Feighery, Department of Immunology, Central Pathology Laboratory, St. James's Hospital, Dublin 8

to arrive not later than 29th June, 1984. (2882)A

THE UNIVERSITY OF WESTERN AUSTRALIA
PERTH
LECTURER IN ZOOLOGY (MAMMALIAN ECOLOGY) (FIXED FERM)

Applications are invited from suitably qualified persons for appointment for three years with some prospects of continuation to a Lectureship in the Department of Zoology. The Department has a tradition of marsupial studies in this appointment wishes to emphasize marsupial population biology. Experpertise in mammalian population biology is sought; previous marsupial experience is not required. The Department runs a number of field stations suitable for the study of marsupial populations. The appointee will lecture to undergraduates generally and in a specialist unit, undertake research, and will be encouraged to lead graduate students.

Current salary range: A24353-$A31994 per annum. Benefits include superannuation, fares to Perth for appointee and dependent family and removal allowance. Conditions of appointment will be specified in any offer of appointment which may be made as a result of this advertisement.

Applications in duplicate stating full personal particulars, qualifications and experience and the names and addresses of three referees, should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia 6009, by 21 July 1984. (W1059)A

UWIST
UNIVERSITY OF WALES

APPLIED BIOLOGY RESEARCH ASSOCIATE (fixed term — 2 years)

supported by the National Kidney Research Fund to work on the regulation of intracellular protein degradation in kidney epithelial cell culture. Experience in tissue culture is desirable.

Salary: Within Range 1A Research and Analogous Staff £7,190 — £8,080 per annum.

Requests (quoting Ref B67) for details and application form to Staffing Office, UWIST, PO Box 68, Cardiff CF1 3XA.

Closing date: 5 July, 1984. (2901)A

CONFERENCES and COURSES

UNIVERSITY OF NOTTINGHAM

MSc COURSE IN AGRONOMY
(the science and practice of crop production)

Applications are invited from Graduates in Agriculture, Horticulture, Agricultural Botany, Plant Science, Ecology, Botany or Biology or other appropriate science subjects for admission to an advanced course of study leading to the degree of MSc (by examination) in Agronomy. The course is designed to provide those having appropriate scientific training with specialist knowledge of agronomy.

The course is of eighteen months duration commencing in January and ending in July of the following year and it consists of four parts:- Principles I includes studies of crop nutrition, fertilizers, weed biology and control, crop water relations and irrigation, variety testing and plant breeders' rights.

Principles II includes computing, crop environment, climatology, biometry, principles of crop protection and crop physiology.

Production I and II provide a detailed study of the production, mechanisation and utilization of agricultural and horticultural crops and grassland, together with field experimentation. In additon each candidate will carry out a research project on an agronomic topic approved by the Head of the Department and will be required to submit a thesis.

For suitable UK applicants, scholarships may be available.

Those seeking admission for the 1985-86 session should write before 15th October 1984 requesting an application form from The Secretary (Ref PGA), School of Agriculture, University of Nottingham, Sutton Bonington, Loughborough, Leics LE12 5RD. (Tel Nottingham 506101 Ext 8156). (2944)C

AWARDS

G.B. MORGAGNI PRIZES

The Fidia Research Laboratories and the Faculty of Medicine of the University of Padua announce the establishment of the G.B. Morgagni Prizes, consisting of one Morgagni Medal and two Young Investigator Awards. These prizes will be awarded every four years on the occasion of the European Symposium on Metabolism, Padua, Italy, commencing in 1985.

Nominations are invited for the Morgagni Medal which is to be awarded to an outstanding European scientist working in the field of metabolism, including metabolic diseases such as obesity, diabetes and hyperlipidemia. The first Medal and US$ 15.000 will be presented at the Fourth European Symposium on Metabolism in Padua, Italy, in May 1985. Each nominee should be nominated by two individuals, who should enclose the nominee's curriculum vitae and send supporting statements of not more than 500 words each. The winner will present a lecture on the occasion of receiving the Medal.

Applications are also invited from European scientists below the age of 40 on January 1st, 1985 and working in the field of metabolism for two Young Investigator Awards, each valued at US$ 5.000, which will be given at the same time as the Morgagni Medal. Applicants should enclose a curriculum vitae and three reprints of the most important papers.

Nominations for the G.B. Morgagni Medal and applications for the Young Investigator Awards should be sent before November 30th, 1984 to:

The Secretary
The G.B. Morgagni Prizes Committee
Istituto di Medicina Interna
Via Giustiniani, 2
35100 - Padova (Italy)

(W1069)N

GRANTS and SCHOLARSHIPS

Requests for Applications For Research Funds

The Health Effects Institute* (HEI) *announces its intention to make available requests for applications for research funds.

The Health Effects Institute is a non-profit research organization founded in 1980. It was established co-operatively by the United States Environmental Protection Agency and the automotive industry but is governed by an independent 3-member Board of Directors: Archibald Cox, Carl M. Loeb Professor, Harvard University; William O. Baker, Chairman Emeritus, Bell Laboratories; and Donald Kennedy, President, Stanford University. The HEI funds research directed to understanding and evaluating the health effects of mobile source emissions. The research program was developed by HEI's Health Research Committee whose chairman is Walter Rosenblith, Institute Professor and former Provost of the Massachusetts Institute of Technology.

The Health Effects Institute currently has thirty studies underway at 25 universities and research centers in 14 states and in West Germany.

This set of research topics is the first set of requests to be issued under the Institute's Phase Two Research Agenda. The topics will be addressed through full research applications on the following subjects:

1. **Mechanisms of carbon monoxide toxicity**
2. **Acute effects of carbon monoxide on cardiac rhythm**
3. **Mechanisms of oxidant injury**

And preliminary applications on:

4. **New methods for assessing health risks from automotive emissions**

In addition to these topics, the HEI will also consider applications in other areas. These include full applications from new investigators and preliminary applications from established investigators on novel and important research in connection with the health effects of automotive emissions.

The Health Effects Institute will make available a packet of descriptive material about the research topics, directions for preparing applications, and material about the Institute to all interested investigators.

All requests and inquiries should be made to or through:
Dr. C. W. Powers, Executive Director, The Health Effects Institute, 215 First Street, Cambridge, Massachusetts, 02142, 617/491-2926.

UNIVERSITY OF LIVERPOOL
LIVERPOOL SCHOOL OF TROPICAL MEDICINE

WOLFSON UNIT OF MOLECULAR GENETICS

POSTGRADUATE SCHOLARSHIP

Applications are invited for a postgraduate research studentship to investigate the molecular biology of microorganisms which determine mating incompatibility in mosquito vectors of disease. Applicants should hold, or expect to gain this summer, a First or Upper Second Class Honours degree in a Biological Science. Experience in techniques of molecular biology would be useful but not essential.

The successful applicant will be expected to register for a higher degree and will join a group working on the application of recombinant DNA techniques to the study of malaria, leishmaniasis and the insect vectors of infections of man.

Applications, including the names of two referees, should be received by The Registrar, The University, P O Box 147, Liverpool L69 3BX. Quote Ref: RV/541. (2899)H

FELLOWSHIPS

THE UNIVERSITY OF LEICESTER

DEPARTMENT OF BIOCHEMISTRY

POST-DOCTORAL FELLOWSHIP

Applications are invited for a post-doctoral research position (MRC-funded) to work on the interaction between tetanus toxin and neural tissue. The project will include studies on (1) the "receptor" for tetanus toxin (2) the biochemical and ultrastructural features of the internalization process and (3) structure function relationships within the toxin molecule itself.

Techniques involved will be in part similar to those previously developed to study the interaction of cholera toxin with target tissues (J. Biol. Chem.256 (1981) 8724), but will also involve the extensive use of monoclonal antibodies.

Applicants should have a PhD in Biochemistry or related discipline, and preference may be given to those with experience in cell culture and immunochemical techniques, and with an interest in membranes.

Salary: £7,190 to £8,080

The position is immediately available although the starting date is negotiable, and will be for a maximum of 3 years.

Applications (along with the names of two referees) should be sent to Dr D R Critchley, Department of Biochemistry, University of Leicester, University Road, Leicester LE1 7RN. (2920)E

UNIVERSITY OF OTAGO

DUNEDIN — NEW ZEALAND

POST-DOCTORAL FELLOWSHIPS

Applications are invited for Post-Doctoral Fellowships in 1985 to be funded and awarded by the University Grants Committee and tenable within the University of Otago.

Awards may be made for one year or for three years.

Applications from candidates wishing to work in any department of the University of Otago will be considered, but in making the awards the University Grants Committee will give priority to current growth research areas such biotechnology, genetic engineering, electronics, engineering, chemistry, etc.

The emolument payable will be at a rate to be determined but not exceeding the lowest step on the University scale for lecturers (currently NZ$21,660 per annum).

Applicants should have completed the requirements for the award of the degree of Doctor of Philosophy.

Application forms and further particulars are available from the Secetary-General, Association of Commonwealth Universities (Appointments), 36 Gordon Square, London WC1H 0PF. Applications close with the undersigned, PO Box 56, Dunedin, New Zealand on 23 July 1984. D W Girvan, Registrar.

(NW623)E

Southampton THE UNIVERSITY

INSTITUTE OF CRYOGENICS

RESEARCH FELLOWSHIP

Applications are invited for a 2 year research fellowship supported by SERC to study convection in cryogenic fluids using Laser Doppler Anemometry and microthermometry. Experience with data processing and lasers preferred.

Salary on range: £7,190 – £8,080 per annum (under review).

Applications giving Curriculum Vitae (in duplicate) and names of two referees should be sent to D.A.S. Copland, Southampton University, Highfield, Southampton SO9 5NH, as soon as possible quoting reference 2056. (2904)E

UNIVERSITY OF WARWICK

DEPARTMENT OF BIOLOGICAL SCIENCES

POSTDOCTORAL RESEARCH FELLOW

A Cancer Research Campaig funded fellowship is available t work with Dr A G Morris in the stud of cell- and molecular-biologica aspects of the production of gamm interferon by human and murin lymphocytes. The position would su best either an immunologist or molecular biologist with an interest i cellular immunology, but an biologist with an interest in the are would be considered. The position tenable for one year, in the first in stance, renewable for at least on further year. The salary will be on th Research IA scale: £7,190 to £11,61 pa. Applicants should send a cv, wit the names and addresses of tw referees, to the Executive Office Department of Biological Science University of Warwick, Coventr CV4 7AL, quoting reference AGM NAR/BS554. (2926)E

UNIVERSITY OF EDINBURGH

DEPARTMENT OF ZOOLOGY

POST-DOCTORAL FELLOWSHIP IN BIOCHEMISTRY

Applications are invited for a SER Fellowship to work on th biochemistry of the yeast cell cycl Research range IA starting 1 Octob 1984.

Further particulars are availab from Professor J M Mitchiso Department of Zoology, Universi of Edinburgh, Kings Buildings, We Mains Road, Edinburgh EH9 3J with whom applications (2 copie including CV and the names of tw referees should be lodged not lat than 9 July 1984.

Please quote reference No 5178. (2311)E

FELLOWSHIPS *continued*

UNIVERSITY OF WATERLOO
Department of Biology
NSERC University Research Fellows

The Department of Biology, University of Waterloo, invites applications for NSERC University Research Fellowships in the following areas of research interest: **(i)** population genetics with emphasis on the genetic structure and dynamics of real as opposed to theoretical populations; **(ii)** nucleic-acid chemistry with emphasis on either *in vitro* DNA synthesis or site-specific mutagenesis; **(iii)** protein chemistry with emphasis on immunological analyses. Applications in other areas will also be given serious consideration. Successful candidates will be expected to establish a vigorous research program and participate in teaching both undergraduate and graduate students.

A curriculum vitae including names of three referees should be sent to Dr. J.E. Thompson, Chairman, Department of Biology, University of Waterloo, Waterloo, Ontario, N2L 3GL. Prospective candidates should examine the NSERC Awards Guide 1984-85, paragraph 186 on page 52 for details.

In accordance with Canadian Immigration requirements, this advertisement is directed to Canadian citizens and permanent residents. (NW611)E

MERTON COLLEGE, OXFORD
JUNIOR RESEARCH FELLOWSHIPS AND SENIOR SCHOLARSHIPS 1985

The college proposes, if candidates of sufficient merit present themselves, to elect to two or three Junior Research Fellowships and to two or three Senior Scholarships in 1985. These awards are open to both men and women. Candidates for Junior Research Fellowships must be under the age of 27 on 1 October 1985; candidates for Senior Scholarships must be under the age of 26, or, in the case of Oxford graduates, must not have exceeded 18 terms from the date of matriculation.

Details of the awards and of the method of appying for them may be obtained from the Warden's secretary, Merton College, Oxford, OX1 4JD. The closing date for applications is SATURDAY 20 OCTOBER 1984. (2929)E

AUSTRALIA

Queen Elizabeth II Fellowships Scheme

PHYSICAL & BIOLOGICAL SCIENCES

To commemorate the Royal Visit to Australia in 1963 the Australian Government established the Queen Elizabeth II Fellowships Scheme. Under this scheme up to ten fellowships may be awarded each year for full-time research by young scientists of exceptional promise and proven capacity for original work. These are post-doctoral awards tenable in an Australian university or approved research institution normally for two years. Tenure of a Fellowship is expected to commence within nine months of the announcement of the award.

QUALIFICATIONS Queen Elizabeth II Fellows must be either Australian or United Kingdom citizens. They should have a PhD., or equivalent qualifications, in one of the physical or biological sciences (which are deemed to include mathematics and the scientific aspects of statistics, engineering, metallurgy, agriculture and medicine). In some circumstances applications may be considered after submission of a thesis, but before the degree has been awarded.

Awards will, in general, be restricted to applicants who are not more than 30 years of age on the date when applications close.

SALARY $25,447 (Australian) per annum — increased to $27,628 per annum at age 28 years.

TRAVEL EXPENSES Necessary travel expenses are payable.

APPLICATIONS Persons interested in applying for the above fellowships should obtain application forms and a statement of the conditions of award from:
Executive Officer, Queen Elizabeth II Fellowships, Department of Science and Technology, P.O. Box 65, Belconnen, A.C.T. 2616, Australia.

The next round of awards will be announced in December 1984. Applications received after the closing date of 15 August 1984 will not be considered. (W1065)E

66181

The Queen's University of Belfast
Postdoctoral Research Fellowship in Food Bacteriology
Department of Agriculture and Food Bacteriology

This MAFF supported Fellowship under the direction of Dr. J.T. Patterson will involve work on the extension of the shelf-life and improvement in consumer appeal of processed meat products. Both microbial and biochemical assessments will be used. The appointment, which is for one year initially, subject to renewal for a further year, is available as soon as possible.
Salary in the range: £7,191-£8,532 per annum with contributory pension rights under USS.
Applications providing full details of qualifications and research experience together with the names and addresses of two referees should be sent to the Personnel Office, The Queen's University of Belfast, Northern Ireland, BT7 1NN, as soon as possible. (Please quote Ref: 84/ N.) (2956)E

THE UNIVERSITY OF AUCKLAND
New Zealand
POSTDOCTORAL FELLOWSHIPS

Applications are invited for Postdoctoral Fellowships to commence during 1985. Applications in any research field (including humanities and social sciences) will be welcomed but preference will be given to those in current growth research areas — biotechnology, genetic engineering, electronics, etc, or in developing fields of economic importance to New Zealand such as tourism.

The Fellowships are available for either one or three years and are valued at NZ$21,660 per annum. Conditions of Appointment and Application Forms are available from the Assistant Registrar (Academic Appointments), University of Auckland, Private Bag, Auckland, New Zealand, or from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications should be forwarded to the University as soon as possible but not later than 28 July 1984. (W1078)E

NUFFIELD FOUNDATION
ONE YEAR SCIENCE RESEARCH FELLOWSHIPS

The Nuffield Foundation is offering to University Lecturers in Science and Applied Science Departments a number of one-year research fellowships to be awarded competitively at the end of 1984 and to be held during the academic year 1985-86. The objective is to enable younger university lecturers to be freed from teaching and administrative duties for one academic year. Preference will be given to applicants under the age of 40. Awards will cover the cost of replacement teaching (up to the fourth point on the lecturer scale) and will include an allowance for research expenses.

The closing date is 14th October 1984 and further particulars may be had from the Director, Nuffield Foundation, Nuffield Lodge, Regent's Park, London NW1 4RS.

This scheme is only open to applicants from Institutes within the United Kingdom. (2951)E

STUDENTSHIPS

SUNDERLAND POLYTECHNIC
DEPARTMENT OF BIOLOGY

SERC Research Studentship

Applications are invited for this studentship (supervised by Dr. W. Arthur and tenable for three years from 1 October 1984) on evolutionary and ecological aspects of competition between species of *Drosophila*.

Applicants should hold a first class or upper second class honours degree in a biological science.

Further particulars available from Personnel Officer, Sunderland Polytechnic, Ryhope Road, Sunderland SR2 7EE, or tel: 0783 76233 ext. 11. Closing date for receipt of applications: 5th July, 1984. (2942)F

UNIVERSITY OF SOUTHAMPTON
Clinical Pharmacology/ Medicine I

SERC (CASE) STUDENTSHIP
Culture and Biochemistry of Human Mucosal Mast Cells

Applications are invited from good honours graduates in biochemistry or related biological sciences to establish tissue culture methods for human mucosal mast cells and to explore the secretory characteristics and biochemical pharmacology of the cells. An SERC (CASE) studentship in collaboration with Roussel Labs is available for 3 years and the successful applicant will be expected to register for a higher degree.

Further information and applications, including curriculum vitae and the names of two referees to: Dr M K Church, Clinical Pharmacology, Southampton General Hospital, Southampton SO9 4XY. Telephone 0703 777222 ext. 4312. Applications close 6th July 1984. Please quote Ref: AJS/84/25/N (2945)F

UNIVERSITY COLLEGE CARDIFF
DEPARTMENT OF PHYSIOLOGY

RESEARCH STUDENTSHIPS

A three year MRC Studentship and an SERC CASE Studentship are available from 1st October 1984. The MRC studentship concerns the properties of primary afferent neurones innervating cranial blood vessels, the meninges and their possible involvement in migraine headache. The project will involve electrophysiological and histological techniques, and is under the supervision of Professor D I Wallis.

The SERC CASE studentship is concerned with the characterisation of 5-HT receptors in the CNS using electrophysiological methods in vivo, and is under the supervision of Dr M H T Roberts.

Applicants should possess, or expect to obtain a First or Upper Second Class Degree in Physiology, Pharmacology or some other appropriate subject.

Those interested should write as soon as possible to Professor D I Wallis or Dr M H T Roberts, Department of Physiology, University College, P O Box 78, Cardiff, CF1 1XL. Ref: 2798. (2940)F

WELSH NATIONAL SCHOOL OF MEDICINE
UNIVERSITY OF WALES
DEPARTMENT OF MEDICINE
SECTION OF MEDICAL GENETICS

RESEARCH STUDENTSHIP IN MOLECULAR GENETICS

Applications are invited for a 3 year position leading to a PhD degree, on the application of recombinant DNA techniques to the analysis of human inherited diseases, in particular myotonic dystrophy and neurofibromatosis.

Further details may be obtained from the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff CF4 4XN. (Tel 0222/755944 Ext 2296) quoting Ref No M6/117 to whom application in the form of a curriculum vitae with the names and addresses of two referees should be submitted. (2924)F

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF METALLURGY AND MATERIALS SCIENCE

RESEARCH STUDENTSHIPS

Applications are invited from good honours (1st or 2(i)) graduates in Metallurgy/Materials Science or related Physical Sciences for 3 year studentships tenable from October 1 1984. The studentships are sponsored by the SERC Quota and CASE schemes, and are in the following areas:

(i) solidification processes in high temperature alloys;

(ii) theoretical and experimental studies of irradiation damage effects in metals;

(iii) modelling deformation and fracture mechanisms in composite materials;

(iv) interfacial structure in semiconductor materials;

(v) structure of complex oxides for advanced batteries;

(vi) structure/property relationships in polymers;

(vii) environmental effects on the strength of graphite.

(viii) embrittlement sensitivity of 9Cr-IMO steel.

Applicants interested in any of these projects should write to The Registrar, The University, P O Box 147, Liverpool, L69 3BX. Quote Ref: RV/543. (2900)F

TRENT POLYTECHNIC
THE DEPARTMENT OF LIFE SCIENCES

invites applications for SERC studentships for work in the following fields of study.

Microbial degradation of xenobiotic chemicals, Neurotransmitter pharmacology, Calcitonin control of blood pressure, Drug transport in liver and kidney, Controlled reproduction of coarse fish, Urea cycle, lysine and ornithine metabolism, Ageing in stored potatoes, Effects of acid rain on amphibia, Physiology and biochemistry of germinating seeds.

Further details and form of application are available from the Staff Officer, Trent Polytechnic, Burton Street, Nottingham NG1 4BU. Applications to be returned as soon as possible. (2981)F

UNIVERSITY OF ASTON
DEPARTMENT OF BIOLOGICAL SCIENCES

RESEARCH STUDENTSHIP

Applications are invited for the above three-year appointment to undertake research, with Dr Hanson and Dr Bailey, into the causes and effects of diabetes and obesity using genetically obese mice.

Applicants should possess, or expect to attain, a degree of Class 1 or 2 (i) in Biochemistry/Physiology or a related discipline.

Further particulars are available from Dr P J Hanson, Department of Biological Sciences, University of Aston, Gosta Green, Birmingham B4 7ET (Tel 021-359 3611 ext 5330), to whom applicants should send a curriculum vitae, together with the names and addresses of two academic referees, by July 6th, 1984. (2974)F

RESEARCH STUDENTSHIPS

A three-year research studentship for the session 1984/85 is available to a suitably qualified candidate (B.Sc, Class 1 or 2:1). The student will be registered for a PhD and will work in the Department of Dermatology under the the supervision of Dr G C Priestley. The award comprises a maintenance grant of £2,430 per annum, plus fees and a small travel allowance.

The project will involve studies of the growth and metabolism of fibroblasts cultured from the skin of patients with scleroderma and lichen sclerosus. Both two- and three-dimensional culture systems will be employed and a range of analytical techniques are available.

Applications should be made to Dr G C Priestley, Department of Dermatology, Phase I, The Royal Infirmary, Edinburgh, EH3 9YW, or by telephone 031-229-2477 Ext 2430, not later than 28 June 1984. (2911)F

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF DENTAL SCIENCES

MRC RESEARCH STUDENTSHIP

Applications are invited from graduates who hold or expect to obtain a first or upper second class honours degree in a biological discipline including an adequate background in biochemistry. A number of research topics are available including studies of the connective tissues of the mouth in relation to periodontal disease and the structure and biosynthesis of salivary glycoproteins and their role in dental plaque formation. The latter project would give scope for a microbiologist.

The successful applicant would join an active team under the direction of Dr G Embery, to whom enquiries may be made. Applications together with the names of two referees should be sent not later than July 9, 1984, to the Registrar, The University, P O Box 147, Liverpool L69 3BX. Quote Ref: RV/548/N. (2946)F

UNIVERSITY OF OXFORD
NUFFIELD DEPARTMENT OF ORTHOPAEDIC SURGERY
MRC BONE RESEARCH LABORATORY

Applications are invited for a

MRC RESEARCH STUDENTSHIP

to join an active research team for work on the differentiation of bone forming cells in normal and pathological conditions with particular reference to the characterisation of cell-specific markers by using monoclonal antibody techniques. Applicants should have, or expect to obtain, a first or upper second class honours degree in a biological science, preferably biochemistry, and will be expected to register for a DPhil degree.

The names and addresses of two referees and a completed curriculum vitae should be sent as soon as possible to Dr J T Triffitt, MRC Bone Research Laboratory, Nuffield Orthopaedic Centre, Oxford OX3 7LD (2938)F

UNIVERSITY OF ASTON IN BIRMINGHAM
DEPARTMENT OF BIOLOGICAL SCIENCES

FACULTY STUDENTSHIP

Applications are invited for a Faculty studentship leading to the degree of PhD commencing October 1984 in the area of experimental and clinical Diabetes Mellitus under the supervision of Dr T Atkins. Candidates should have, or expect to have a first or upper second class honours degree in Biochemistry/Physiology or a related subject.

Applications which should include a curriculum vitae, telephone number and the names of two referees, should be sent to Dr T Atkins, Department of Biological Sciences, University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET (2952)F

STUDENTSHIPS

BRUNEL UNIVERSITY

Cell Biology Research Group

Applications are invited for a postgraduate research studentship, funded by the Cystic Fibrosis Research Trust, for a study of evasion of macrophage functions by Pseudomonas aeruginosa. The project will be supervised jointly by Drs Susan Smith and Roger Dean. The successful candidate will be registered for a PhD degree and should hold or expect to obtain a good honour degree in an appropriate subject.

Applications, including a curriculum vitae and the names of two referees, should be sent to Dr S E Smith, School of Biological Sciences, Uxbridge, Middlesex UB8 3PH, from whom further information is also available. (2943)F

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF PHYSIOLOGY

RESEARCH STUDENTSHIPS

Projects available in muscle physiology, cortical neurophysiology and developmental neurobiology. Facilities for work in vivo and in vitro.

Postgraduate Advisor, Department of Physiology, UCL, Gower Street, London WC1E 6BT. (2950)F

PROPOSED UNIVERSITY OF ULSTER
Faculty of Science

SERC CASE STUDENTSHIP IN PHYSICS
(in collaboration with Culham Laboratory)

Applications are invited for a research Studentship to study the production of negative hydrogen ions in plasma sources. The project will involve the student in the design, operation and diagnosis of plasma generators and extraction systems for the intense neutral beam injection systems for heating nuclear fusion plasmas. The work will be carried out at both the Coleraine Campus of the University and the Culham Laboratory.

Candidates should have or expect to obtain an upper second class or first class honours degree in physics or a similar discipline.

Further details may be obtained from the Academic Registrar (Designate), The University of Ulster, PO Box 35, Coleraine, Northern Ireland BT52 1SA, to whom applications, in the form of a curriculum vitae and the names and addresses of two referees, should be sent by 11th July, 1984.

Note: a petition for a charter for the proposed University of Ulster has been submitted to the Privy Council by the New University of Ulster and the Ulster Polytechnic. The petition proposes the merger of the two institutions with effect from 1st October, 1984. (2983)F

UNIVERSITY OF CAMBRIDGE

RESEARCH STUDENTSHIP IN ORGANIC CHEMISTRY OR BIOCHEMISTRY

Applications are invited from those graduating in the above fields to work on the synthesis and testing of novel arsonic acids, in which the $-CH_2-AsO_3H_2$ group replaces the $-O-PO_3H_2$ group of natural metabolic intermediates. Such analogues, e.g. of nucleotides and glycolytic intermediates, can be 'uncoupling agents', because they can be enzymically phosphorylated to form compounds that spontaneously hydrolyse to the starting analogues.

Applicants should be eligible to hold an SERC training grant. They should send a Curriculum Vitae and ask two referees to write about them, by Monday, 9 July to Dr H B F Dixon, Department of Biochemistry, Tennis Court Road, Cambridge, CB2 1QW; further details are available from him. (2972)A

UNIVERSITY OF CAMBRIDGE
Division of Virology
DEPARTMENT OF PATHOLOGY

POST-GRADUATE STUDENTSHIP IN VIROLOGY

Applications are invited for an MRC-funded studentship starting 1 October 1984. The project is to investigate interactions between herpesvirus proteins and antiherpes drugs and will involve the cloning, in vitro manipulation and expression of herpes genes in E coli.

Applicants should have or expect to obtain a first or upper second class honours degree in a biological science and should send a curriculum vitae together with the names and addresses of two referees as soon as possible to Dr G Darby, Division of Virology, Department of Pathology, Tennis Court Road, Cambridge CB2 1QP. (2980)F

NATIONAL INSTITUTE FOR MEDICAL RESEARCH
POSTGRADUATE RESEARCH STUDENTSHIPS

Applications are invited for two MRC-funded postgraduate research studentships tenable from October 1984, in the divisions of Parasitology and Physical Biochemistry. The projects are entitled:

1. The identification and molecular cloning of stage-specific genes of Trichinella spiralis (supervised by Dr A J G Simpson and Dr S R Smithers)

2. Energy transduction in muscle (supervised by Dr M A Ferenczi)

Candidates should have, or expect to obtain, a first or upper second class honours degree in a biological science subject.

Applications including a Curriculum Vitae and nominating two academic referees should be made to the Director of Postgraduate Studies, at the National Institute for Medical Research, before 10th July 1984.

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF BIOCHEMISTRY

SGRC STUDENTSHIP IN STEROID BIOCHEMISTRY

Applications are invited for the above studentship, tenable for three years commencing October 1984. Candidates must hold, or expect to obtain, a I or II(i) Honours degree in an appropriate subject, and will be expected to register for a higher degree.

The project involves studying the relationship between sex steroids and the endometrium, particularly with respect to implantation, in cases of sub-fertility. The work will be carried out in the Department of Obstetrics and Gynaecology, but the student will also be a member of the Departmentof Biochemistry.

Applicants should write, giving names and addresses of two referees and enclosing a curriculum vitae to Dr P V Maynard, Department of Obstetrics and Gynaecology, University Hospital, Queen's Medical Centre, Nottingham, NG7 2UH. (2903)F

MISCELLANEOUS

RESEARCH VESSEL FOR ECONOMICAL WORLD WIDE CHARTER

A 55'6" × 19' crabber/seiner design of Ed Monk with a range of 6,000 miles at eight knots. Party of six, experienced crew, extensive electronics including SATNAV.

Spice Island Traders, One Boston Place, Boston, MA 02108 (617) 723-1955. (NW750)J

APPOINTMENTS WANTED

RECENT PhD BIOCHEMISTRY — Protein Chemistry/Enzymology. Experienced with many laboratory techniques such as immunochemistry, isoelectric focusing, etc., and instruments such as CD, NMR, fluorometry, etc. Seeks position as postdoctoral/research associate/teaching. Available immediately. Reply to Box 42, Nature, 15 East 26th Street, New York, New York 100100, USA. (NW608)B

APPOINTMENTS WANTED advertise your qualities and qualifications through the most influential science weekly in the world at a special reduced cost of *25p a word.* (Personal Box Numbers £2). Advertisements must be pre-paid and sent to: Nature Classified (Appts Wtd), 4 Little Essex Street, London WC2R 3LF. (890)B

ASSISTANTSHIPS

QUEEN MARY COLLEGE
University of London
MATERIALS DEPARTMENT

Applications are invited for a

POSTDOCTORAL RESEARCH ASSISTANTSHIP

on a collaborative project between Professor W Bonfield (QMC) and Dr J Bowman (Brunel University) concerned with the development of novel biodegradable composites for an application as bone-fracture fixation plates. The project forms part of an extensive research programme on the biomechanics of bone and bone-replacement materials. A PhD in Materials Science or a relevant discipline is essential and experience in polymer or composite processing and characterisation techniques is desirable. It is intended that the Research Assistant be mainly based at Brunel. Appointment for 2 years in first instance at initial salary in range (under review) £7,190-£8,530 plus £1186 London Allowance. Please apply by letter, enclosing cv and names of 2 referees, to The Senior Personnel Officer, Queen Mary College, Mile End Road, London E1 4NS, by 5 July. (2965)P

UNIVERSITY OF ABERDEEN

DEPARTMENT OF FORESTRY

RESEARCH ASSISTANTSHIP

Applications are invited for a Research Assistantship tenable for three years from October 1984, to study ion exchange at leaf surface as part of a wider study on the impact of acid rain.

The salary will be on the 1B scale for Research and Analogous Staff — £6,310 to £8,530 per annum (under review).

Application forms from the Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 15 July 1984. (2949)P

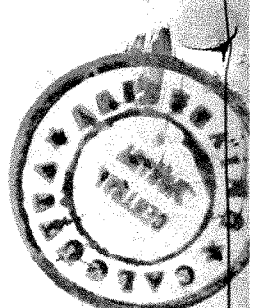
UNIVERSITY OF OXFORD

DYSON PERRINS LABORATORY

RESEARCH ASSISTANTSHIP

Applications are invited for a post doctoral Research Assistantship (supported by SERC) for studies on the total enantiospecific syntheses of natural products (including sesbanimide and polyhydroxylated alkaloids) from carbohydrates.

The appointment is for one year at this stage from 1 October 1984, or a later mutually agreeable date and is renewable. Salary will be within the range £7,190 - £8,530 pa (Range 1A, Research and Analogous Staff Scales).



Applicants should send their curriculum vitae, and ask two referees to send letters of recommendation directly to, Dr G W J Fleet, Dyson Perrins Laboratory, Oxford University, South Parks Road, Oxford, OX1 3QY as soon as possible and in any event before August 31. (2963)P

Typesetting: J.W. Arrowsmith Ltd, Bristol and Cutline Graphics Ltd., London EC4Y 0HP. Printing: Kingsdale Press, Reading, Berks, member of the St. Ives Group, in association with Godfrey Lang Ltd, London WC1R 4EB and The William Byrd Press Inc., Richmond, Virginia, USA. Published by MACMILLAN JOURNALS LTD, 4 Little Essex Street, London WC2R 3LF. — 21 June 1984.

CANAL FUNCTIONS IN FORAMINIFERA

Say goodbye to soft gels

Trisacryl separates better and faster

The built-in magic of matrix engineering gives you form, porosity, strength and hydrophilic behaviour. Just pure chemistry. Hard. Inert. Synthetic. The ultimate support — Trisacryl®. Whether for Affinity, Ion Exchange or Gel Filtration, Trisacryl is engineered to give you better results — guaranteed!

Get the facts in our new catalogue and give yourself a whole new scenario of problem-free chromatography.

Trisacryl is developed and manufactured by IBF
Pointet-Girard (Rhône Poulenc Group)

JUST THE TICKET!

Yes, we're offering season admission tickets to Laboratory '84... ABSOLUTELY FREE. And you can have as many extras as you want so your friends and colleagues can attend Britain's premier scientific industry event too.

THE EXHIBITION

There is literally no other exhibition in the United Kingdom, of this scale and importance, which serves the needs of scientists and technologists from all branches of industrial and medical science and related academic disciplines. 'Laboratory' is sponsored by the world's most eminent professional and trade bodies – including The Royal Society of Chemistry, The Scientific Instrument Manufacturers' Association, The British Laboratory Ware Association and The Chromatography Discussion Group. Virtually every manufacturer and supplier of consequence will be represented at 'Laboratory', and the products of some 600 companies from around the world will be on display. There's even an official group coming all the way from Australia!

THE CONFERENCE

There is a major conference for analytical science – 'Analyticon' – alongside the exhibition. It caters for scientists and technologists from all branches of industrial science, medical science and related academic disciplines where analytical techniques play an important role. 'Analyticon' is organised by The Scientific Instrument Manufacturers' Association and sponsored by both The Royal Society of Chemistry and The Chromatography Discussion Group. Delegates are expected from more than 20 countries and the scientific programme will cover six main themes: Computers in the laboratory; Chromatography; Molecular Characterisation & Surface Analysis; Elemental Analysis; Clinical Analysis & Bio-sciences; Electroanalytical Chemistry.

Circle No.03 on Reader Service Card.

LABORATORY/ANALYTICON '84
At The Barbican, City of London,
4th-6th September 1984.

Upon receipt of the completed coupon, we will immediately send you as many free admission tickets to 'Laboratory' as you require, and a free copy of our 100+ page catalogue will be available on the door. Please remember to tick the appropriate box if you also require information for delegate registration at 'Analyticon'.

Telephone (Saffron Walden) 0799 26699 if you have any questions or telex 81653 Inform G.

Please send me a free season ticket and ☐ for my colleagues. I also require details and costs for delegate registration of the Analyticon Conference. ☐ Please tick.

PLEASE PRINT

LABORATORY '84: THE BETTER PLACE TO BE

Recent developments in molecular biology, many of which have been described by their authors in *Nature*, are helping to clarify the causes of cancer. With each passing week, more and more people consider that a full understanding of cancer cannot be long delayed. But the implications for physicians and their patients are still entirely unclear.

Organized and presented by NATURE, the international journal of science

Perhaps the most important international conference you could attend in 1984. Devoted to the recent contributions of molecular biology to the understanding of malignant disease.

For Research Scientists and Clinicians

IN SEARCH OF UNDERSTANDING...

THE MOLECULAR BIOLOGY OF CANCER

This is why NATURE has chosen to devote its third international conference to an occasion when researchers in the life sciences and clinicians can assess the importance of recent developments in molecular biology for the understanding and ultimately for the treatment of cancer.

SEPTEMBER 10, 11, 12, 1984
BOSTON PARK PLAZA HOTEL

Park Plaza at Arlington Street
Boston, MA 02117 U.S.A.

The conference program has been designed for two groups of people—researchers in the life sciences anxious to learn about and discuss the latest developments in the molecular biology of cancer, and physicians who consider that these developments may eventually affect their own work with patients.

Participation in the conference will be restricted so as to provide opportunities for those participating to mix with and to question those responsible for the latest research.

To this end, the leading scientists making formal presentations will also take part in two-hour round table discussions, providing an ample and unusual opportunity for participants to take part in detailed discussions and to make short presentations of their own.

To take part in this important and novel conference, register now and book your rooms (also limited) at the Boston Park Plaza Hotel and Towers.

TO REGISTER FOR THE CONFERENCE: Return the form with your check, credit card authorization or an authorized purchase order. Full 3-day registration fee is $325.

THE SETTING: Boston Park Plaza Hotel and Towers, Boston located at Park Plaza and Arlington Street, just off the famous Boston Public Gardens and Common.

ROOM RESERVATIONS: A large block of rooms has been set aside for attendees, but we do suggest that you reserve your accommodations early, to avoid disappointment. Rooms must be reserved directly with the Hotel, at (617) 426-2000, or 800-225-2008, Telex: 710 321 1088. Be certain to mention your participation in the "Nature Conference", to take advantage of these special lower rates: Singles: $70, $80 & $85; Double: $85, $95 & $100.

CONFERENCE DINNER: The Conference dinner will be held on Tuesday evening, September 11th, in the Imperial Ballroom. TO INSURE SEATING AT THE CONFERENCE DINNER, please include your dinner ticket requirements and payment of $25 per person with your Registration.

POSTER SESSIONS: Please write with a title and a brief synopsis, to the Posters Editor, Nature Publishing Co. 15 E 26 St., N.Y., NY 10010.

RECRUITMENT CENTER: Private meeting rooms and staff will be provided for recruitment executives and scientists to discuss employment opportunities. Contact: Miss Gene Fein, Recruitment Services Manager, Nature Publishing Co., 15 E 26 St., N.Y., NY 10010, (212) 689-5900.

THE MOLECULAR BIOLOGY OF

CANCER

Conference Program
September 10-12, 1984
Boston Park Plaza Hotel

Daily Themes:

DAY 1 - ONCOGENES,
DAY 2 - THE CANCER CELL,
DAY 3 - PROSPECTS/PROBLEMS.

MONDAY, 10 September
Exhibition Viewing: 8:30am — 6:30pm
Recruitment Center: 9:30am — 6:00pm

DAY 1
ONCOGENES AND GROWTH FACTORS — WHAT THEY ARE AND WHAT THEY DO

9:00 — 9:15	**Chairman**
9:15 — 10:00	Oncogenes *R. Weinberg (MIT)*
10:00 — 10:45	Growth factors *M. Spom (NIH)*
11.15 — 12.00	HTLV *R. Gallo (NIH)*
12.00 — 12.30	Clinician's view *S. Broder (NIH)*
2.00 — 4.00	Round table with morning speakers
4.30 — 5.30	The cancer cell *J. Cairns (Harvard)*

DAY 2
TUESDAY, 11 September
Exhibition Viewing: 8:30am — 6:30pm
Recruitment Center: 8:30am — 6:00pm
THE CANCER CELL — HEREDITARY CANCER, TUMOR PROMOTERS AND CARCINOGENESIS

9.00 — 9.15	**Chairman**
9.15 — 10.00	Gene regulation *P. Leder (Harvard)*
10.00 — 10.45	Hereditary cancer *R. White (Utah)*
11.15 — 12.00	Carcinogens and promoters *I.B. Weinstein (Columbia)*
12.00 — 12.30	Clinician's view *F. Gilbert (Mt Sinai)*
2.00 — 4.00	Round table with morning speakers
4:30 — 5:30	*The Pattern of Cancer R. Peto (Oxford)*

WEDNESDAY, 12 September
Exhibition Viewing: 8:30am — 3:00pm
Recruitment Center: 8:30am — 3:00pm

DAY 3
PROSPECTS AND PROBLEMS — DRUG RESISTANCE, MONOCLONAL ANTIBODIES AND NEW DRUGS

9.00 — 9.15	**Chairman**
9.15 — 10.00	Diagnostics and therapeutics *G. Todaro (Oncogen)*
10.00 — 10.45	Immunotoxins *J. Uhr (Texas)*
11.15 — 12.00	Drug resistance *A. Varshavsky (MIT)*
12.00 — 12.30	Clinician's view *J. Gutterman (Houston)*
2.00 — 4.00	Round table with morning speakers
4:00 — 4:45	NCI Program *P. Greenwald (NIH)*
4:45	Closing remarks

TO REGISTER FOR THE CONFERENCE, mail this form with your payment.

N w biotin-st ptavidin systems from Amersham

Your flexible approach to:

- ELISA/radioimmunodetection assays
- protein blotting
- immunocytochemistry

Designed to provide you with:

- high sensitivity
- low backgrounds
- flexibility:
  - Extensive range of biotinylated
    - whole antibodies
    - $F(ab')_2$ fragments
    - protein A
  - Wide choice of labelled streptavidin derivatives
    - ^{125}I
    - enzyme
    - fluorescent

For more details of this high performance detection system, please contact our Research Products Technical Service department or your local representative.

nature

NATURE VOL. 309 28 JUNE 1984

COVER

The role of the elaborate canal system found in the walls of the test of foraminiferans has been obscure. The Recent nummulitid *Heterostegina depressa* d' Orbigny 1826, shown on the cover, has just released gametes through canals connecting the lumen with the surrounding seawater — this is one of the functions of the canal system described on p.789.

SCIENCE IN THE LOW COUNTRIES

- *Will the policy of "concentrating" the universities in Holland and Belgium create more problems than it solves?*
- *Is Belgian science stagnating?*
- *What would be the effect of increased government control over Dutch research policy?*

These and other questions are examined in *Nature*'s special supplement on Science in the Low Countries.
Extra copies of this issue are available now from the address given below.

GUIDE TO AUTHORS

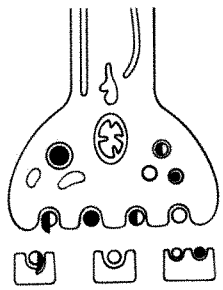
Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.



Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

Co-transmission

Proceedings of a Symposium held at Oxford during the 50th Anniversary Meeting of the British Pharmacological Society

Edited by **A.C. Cuello**
University Department of Pharmacology, Oxford
£45 280pp ISBN 0 333 32592 3

There is now compelling evidence that neurons might synthesise, store and release more than one neuroactive substance – a concept that will profoundly change our understanding of the pharmacology of the central and peripheral nervous systems. This book investigates the most representative arguments currently being put forward on this new topic.

Contents

Foreword – *Sir William Paton*; Preface; Coexistence of traditional neuro-transmitters with peptides in the mammalian brain; S-hydroxy tryptamine and substance P in the raphe and γ-aminobutryic acid and moblin the cerebellum – *V. Chan-Palay*; Coexistence of putative neuromodulators in the same axon; pharmacological consequences at receptors – *E. Costa*; Neuronal coexistence of putative transmitters in the spinal cord and brainstem of the rat – *R.F.T. Gilbert*; Coexistence of classical transmitters and peptides in neurons – *T. Hokfelt et al*; The adrenal medulla: a model for studying synthesis, co-storage and co-secretion of peptides and catecholamines – *O. Humberto Viveros and S.P. Wilson*; The co-transmitter hypothesis, with special reference to the storage and release of ATP with noradrenaline and acetylocholine – *G. Burnstock*; Coexistence of neuractive substances as revealed by immunohistochemistry with monoclonal antibodies – *J.V. Priestly and A.C. Cuello*; Coexistence of monoamines in peripheral adrenergic neurons – *G. Jaim-Etchevery and M. Zieher*; Coexistence of neurotransmitter substances in a specially defined invertebrate neurons – *N. Osborne*; The diffuse neuroendocrine system: an extension of the APUD concept – *A.G Pearse*; Neuropharmacological and neurophysiological consequences of the co-release of neurotransmitters – *R.W. Ryall*; Coexistence of adenosine S-biphosphate and acetylcholine and the electromotor synapse – *H. Zimmerman*; Index

How to order an East–West thaw

The word in Washington is that the administration is about to try again for better scientific relations with the Soviet Union. The goal should be to put any new initiative on a permanent foundation.

THE tale of how Sir Humphry Davy went on a tour of mainland European laboratories at the height of the Napoleonic Wars is widely regarded as a proof that the international character of science was then more highly regarded than now. That Davy, to whom uxoriousness came late, was also on his honeymoon, makes the journey all the more remarkable. Certainly things are different now, as the near-collapse of scientific relations between the West and the Soviet Union demonstrates all too clearly. Part of the explanation is that research is now recognized to bear on the immediate strategic interests of governments. It also matters that the scientific community everywhere is now dependent on governments for financial support, and thus constrained. But, since the early nineteenth century, procedures by which the movement of people from one country to another is regulated have also been formalized and tightened, partly in response to the flourishing of the technology of travel but also, one suspects, often for its own sake. The time, however, has come to ask that the present parlous condition of East–West relations should not be allowed to continue as it is.

The issue is urgent not merely in its own right but because, by some accounts, President Reagan was earlier this week about to advocate in public a renewed attempt to foster scientific relations between the United States and the Soviet Union. Many outside the Soviet Union will be surprised by this development, not least Dr Frank Press, president of the National Academy of Sciences in Washington. Earlier this summer, Dr Press announced his intention of travelling to the Soviet Union to breathe new life into the largely defunct exchange programme with the Soviet Union. Dr George Keyworth, President Reagan's science adviser, said at the time (see *Nature* 10 May, p.105) that he was "surprised" at this development. But then, with anxiety about the condition of Andrei Sakharov mounting, Dr Press put off his visit. Other academies in the West have responded similarly to recent developments. In London for example, the Royal Society declined a formal invitation to last week's conference in Moscow to celebrate the twenty-fifth anniversary of the Institute of Biochemistry, now run by Academician Y. A. Ovchinnikov. President François Mitterrand, as the world now knows, has chosen a more direct way of dealing with a delicate problem of diplomatic etiquette; last week, in Moscow to seek some basis for continuing East–West negotiations on arms control, he spoke up about Western anxiety about Andrei Sakharov — and had his remarks on the subject censored from *Pravda*'s otherwise complete account of what he had to say.

A sorry tale

The recent deterioration of East–West relations is so familiar and depressing that it hardly bears recitation. Underlying the sorry tale is a sequence of calamitous developments that can be counted as misunderstandings only by the exercise of the utmost charity. The Soviet deployment dating from the mid-1970s of SS20 missiles within striking range of Western Europe broke the spirit but not the letter of the SALT II agreement on strategic arms. Soviet signature in 1975 of the Helsinki agreement within the framework of the Conference on Security and Cooperation in Europe, which among other things provided for a measure of liberality in governments' dealings with their people, did not prevent the arrest of members of the Helsinki monitoring group set up in Moscow. The Soviet intervention in Afghanistan at the end of 1979, ostensibly at the invitation of the government in Kabul, was a more serious setback; the then President Carter gave that as his reason for not sending the SALT II treaty to the Senate for ratification, although by then it was already probable that he would have been given a dusty answer.

Serious interruptions of agreements on the East–West exchange of scientists date, however, from this time. So do the efforts in the United States to restrain the "haemorrhage" of Western technology to the East, with the variously grudging consent of Western Europe and Japan. The exile (to Gor'kii) of Andrei Sakharov, and his subsequent ill-treatment, seems to many to have been the last straw.

Principles

Neither East nor West has dealt rationally with the several sorry events in this unpleasant history. The principles that allowed Humphry Davy to go gallivanting in mainland Europe when France was at war with most other European states seem to have been forgotten. Put simply, they are these. While national governments have necessarily become the chief sources of support for scientific research in all fields, governments have not by that circumstance bought the scientific enterprise, which remains the collective property of its practitioners. And while professional people owe their national governments allegiance of the kind required by the civil law (which varies from place to place), they also owe their profession the duty of acknowledging the international character of what they do. East–West rivalry in military development and in the commercial exploitation of technology, unavoidable at some level, paradoxically must coexist with East–West interdependence in basic science. That is the simple truth that the Pentagon's planners seem only with difficulty to have appreciated in their schemes for restricting visits for foreigners to US laboratories. Exactly the same principle works in the opposite direction, Moscow's puzzlement at the West's indignation over Sakharov notwithstanding.

The translation of these principles into practice should not be as difficult as it is often made to seem by the self-contradictions of governments and the hesitancy of professional people.

If the Soviet Union should send its military forces into Afghanistan on a trumped-up excuse, shoot down a Korean civil aircraft or walk out of negotiations on arms control, that is no reason why the East–West migration of scientists should be constrained. But, naturally, visitors in one direction or the other, being adult electors as well as scientists, will or should be unrestrained in saying what they find objectionable in the policies of their hosts' government. Because of the belief, common in the West and justifiable, that Soviet citizens are not always allowed to judge for themselves what is the truth about political developments, it is inconsistent that exchange programmes should be cancelled or reduced at times when, in a small way, they might contribute precisely to the kind of enlightenment that is supposedly lacking. It is, however, important that these opinions should be advanced only in ways consistent with local civil law and in a manner that does not impede the chief purpose of a visit (which usually, in practice, means privately and not in public). Arguments about the relative durability of communism and capitalism, often entertaining, are irrelevant.

Indignation about the ways in which scientists are dealt with can be accommodated within the framework of seemly East–West relations only with greater difficulty. The Soviet Government's justification of its treatment of Sakharov is logical enough. That a senior physicist, with such important contributions to the Soviet nuclear weapons programme to his credit, should have lapsed into such outspoken criticism of Soviet military and social policies, is regarded as disloyalty bordering on treachery. That view is consistent with the Leninist adaptation to modern times of the feudal Russian doctrine that people are the property of the state. (Soviet apologists for Sakharov's treatment are forever saying that he remains a member of the Soviet academy, with the appropriate salary, but that is beside the point.) What the Soviet Union appears not to understand is the offence which has been given in the West by its treatment of a distinguished if now dissident scientist which, while falling short of outright imprisonment, deprives the scientific community of such contributions as he may still have to make. (It is, on the other hand, unreasonable that Sakharov and his wife should appear to be asking, in a state whose civil laws restrict the freedom of people to move elsewhere — Helsinki notwithstanding — to be allowed medical treatment in the West.)

President Mitterrand seems to have sensed what these circumstances require with his statement in Moscow last week. There is every reason why lesser mortals should, in lesser ways, follow his example. The case is simply that it is a shabby way to treat a distinguished scientist, however troublesome he may have become, to pack him off to a provincial city out of touch with work, friends and colleagues. To say this when asked, and to volunteer the opinion should opportunity arise, need not cause rancour and may in the long run help Sakharov or at least the principles of civility. Better to seize the opportunity than to spurn it, either from embarrassment or in the belief that huffy silence will miraculously be more effective.

That is the most tricky part of the West's case for restoring East–West scientific relations. Let us hope that President Reagan's rumoured intentions materialize — and that the Soviet Union responds positively. But this time, at the umpteenth time of blowing hot, it is also important that the effort should be seriously intended. Nothing so permanently damages East–West relations as a set of formally negotiated agreements that is then vicariously abandoned because of some unrelated happening. So it would be useful to wring from the US Administration an undertaking that if East–West relations are now to be improved, there will be an understanding that they will not in future be put at hazard for political reasons having nothing to do with science. Although the US State Department has been quietly pragmatic in its administration of US–Soviet collaborations even in the past few difficult years, the simplest way of making sure that programmes now agreed continue is to delegate responsibility for them entirely to the National Academy in Washington which, with egg on its face since Dr Press blew hot, then cold, may be needing a little reassurance. □

New exams for old

Britain's plan to reorganize school examinations is sensible, but should be taken further.

THE British Secretary of State for Education and Science, Sir Keith Joseph, last week found himself the unaccustomed object of extravagant praise from all quarters of the British educational establishment. The occasion for this achievement, all the more remarkable in the atmosphere of ill-feeling left by strikes by teachers (over pay) in the past few weeks, was Sir Keith's decision finally to end the archaic and unfair two-tier system of examinations for 16-year-olds. For the past thirty-five years, there has been the "O" (for "ordinary") level of the General Certificate of Education (GCE) and, for twenty years, the Certificate of Secondary Education (CSE) for generally less able students. The notion that the two systems should be merged has been promoted for almost as long as they have co-existed. Five years ago, the present government shelved a plan to merge the systems on the grounds that what it called "standards" would be undermined. Sir Keith's conversion to the educationalists' cause is belated, but none the less welcome on that account. The parable of the prodigal son refers. Will the lessons that have been learned, painfully it appears, now be applied elsewhere in the British educational system?

Sir Keith Joseph's scheme will by 1988 do away with the present jungle of 20 separate examination boards administering an astonishing 19,000 syllabuses for 16-year-olds. The confusion they have entailed has brought the whole examination system into disrepute: it is widely known that (for whatever reasons) the standards of some boards are substantially lower than those of others, even when the qualifications awarded are nominally the same. The boards will now be brought together into five groups to administer a single General Certificate of Secondary Education. Examinations under the new scheme will incorporate differentiated papers or questions that will be assessed to nationally-agreed criteria, thus making them applicable over a much wider ability range than the existing examinations. Students will not therefore have to choose — or, more often, be pushed — between examinations to which, for reasons of parental pride or teachers' convenience, they are not suited. National grade-related criteria now under development will in principle allow a more objective interpretation of examination results — and are indeed essential if the merger is to succeed. In a skilful compromise that seems to have avoided the inevitable accusation that a change will result in lowered standards, Sir Keith has been able to give an assurance that the performance represented by the three highest grades of the set of seven grades in the new examination will correspond to those of the old "O" level.

Why has this apparently obvious rationalization taken so long to decide? The British Government has consistently made clear its position that any integration of GCEs and CSEs would have to wait upon an acceptable agreement on national criteria for syllabuses and assessment procedures, and much effort has been expended towards this end by the examinations boards. Despite a few minor hiccups, such as the minister's reluctance at the outset to accept that a physics examination should include some questions on social and economic issues, the draft criteria have won reasonably wide support. (Even so, its draft criteria for biology at 16 includes no explicit reference to the theory of evolution.) What has been achieved shows that a national consensus on core subject content is feasible.

So will Sir Keith stop now that he has brought about his thoroughgoing revision of the national system of examinations at 16? The existing advanced level examinations ("A" levels), taken by those who choose to study until 18, are just as varied and just as much in need of revision, although their faults are different. In an effort to achieve more uniformity of content, nine examinations boards offering "A" levels have put out a document called *Common Cores at Advanced Level*, but this represents little more than the intersection of the separate syllabuses. And the boards have not yet been able to agree on even this much, with one or other of them declining to accept such-and-such a topic for inclusion. Although the notion that the existing "A" level examinations provide an education that is too narrow for the important years between 16 and 18 is widely accepted, yet, in the present state of anarchy, it is hard to see where a sensible revision in the direction of more generality could start.

The simplest solution would be to abolish this second tier of examinations. But how then would the universities know which school-leavers are best-suited to be students? That would be the academics' cry. There are two answers: provide a university entrance examination (as, for example, in the United States) and abolish the need for school specialization by not expecting most undergraduates to scamper through a first-degree course in just three years. For most British school-leavers who do not go on to further education, some of the time and effort that would be saved by the elimination of over-specialized teaching in secondary schools could be usefully spent in teaching other modern skills, from driving cars to operating computers. □

US space station

NASA negotiates on several fronts

Washington

THE National Aeronautics and Space Administration (NASA) is bracing itself for a complex series of negotiations with Europe, Congress and the space science community before it finalizes plans to build the $8,000 million manned space station called for by President Reagan in his State of the Union message earlier this year.

In Washington last week, a delegation from the European Space Agency (ESA) settled down for what is expected to be a difficult round of talks with NASA about the cost and scope of European participation. NASA, under pressure from Congress and the Office of Management and Budget (OMB) to keep the costs of the station as low as possible, hopes to persuade foreign countries to pay up to 30 per cent of the station's cost.

But the Europeans, who are likely to account for between 15 and 20 per cent of the foreign contribution, are expected to drive a hard bargain.

At a meeting in Naples earlier this month, ESA officials said their member governments wanted to be more than subcontractors; they would be willing to join the project only as full partners able to garner the expertise necessary to launch a station of their own, perhaps a decade or so after the US station is launched in 1992. And to avoid repeating their mistakes with Spacelab, they are insisting on guarantees of equal access to the space station and the right to exploit it commercially.

Foreign participation is not the only difficult question NASA has to resolve, however. Although Congress has agreed to provide NASA with the $150 million it wants in 1985 for preliminary design studies, both houses have signalled that they are not yet fully convinced of the need for the elaborate permanently manned facility planned by the space agency. Bills passed by the Senate and the House of Representatives instruct NASA to set aside several million dollars for "complementary" design studies of a less grandiose "man-tended" facility.

Some congressional champions of the space station objected to the requirement for the complementary studies, arguing that it would send "mixed signals" to the private companies looking at the possibility of investing in manufacturing and research in space. But most members felt it was prudent to keep options open as long as possible, in case budget retrenchment later in the decade shoud leave NASA with a half-completed "'hotel in space".

Meanwhile, NASA is negotiating on a third front, with the US space science community. Although at the outset opposed to the decision, space scientists have wasted no time in joining the planning effort to ensure that the scientific yield from the project is as great as possible. Earlier this month, a newly-established advisory committee on the scientific uses of the space station, under the chairmanship of Dr Peter Banks of Stanford University, recommended that the space station should be accompanied by a flotilla of compact free-flying modular platforms rather than the one or two large unpressurized platforms envisaged by NASA.

A minority of members of the committee is also anxious to persuade NASA to complement the space station, which is to maintain a 400-km east–west orbit at an inclination of 28.5 degrees, with a large free-flying platform in polar orbit. The polar module has been talked about within NASA but is regarded as a prime candidate for cutting in the event of budget difficulties or escalating costs. The platform, regarded as essential by the Earth-observation sciences, is expected to cost at least $800 million.

Peter David

Commercialization of space

Whoever will pay the price?

Washington

US BUSINESS corporations are asking for extensive government subsidies and risk-sharing agreements before agreeing to take up President Reagan's call for the rapid commercialization of space. In Congress last week, leaders of three major aerospace corporations said that, without government help, the costs and risks associated with the exploitation of space are simply too high for it to be worth their while to be involved.

The witnesses, from the Fairchild, Grumman and McDonnell Douglas corporations, are all members of an industry-space commercialization committee which recently submitted a swathe of detailed recommendations to the White House. Although the report has not been published, it is clear that it calls for substantial tax incentives, some form of risk-sharing agreement and enhanced private sector access to the facilities and technical expertise of the National Aeronautics and Space Administration (NASA).

Mr Richard Kline, director of space station operations for the Grumman Aerospace Corporation, told the House of Representatives' subcommittee on space science and applications that the venture capital market rarely finances ventures costing more than $75 million and is too small to support significant investments in space. To help companies reduce their initial investment risk, he said, NASA ought to provide "seed money" for the development of initial projects and reduce the flight of shuttle rides. He also called on NASA to expand its effort in promising areas of basic research such as microgravity and high vacuum environments.

Dr John Townsend, president of the Fairchild Space Company, said a number of complex fiscal and regulatory barriers would have to be removed before the private sector could exploit the full commercial potential of space. The major problem, he said, was that since space is not legally part of the United States, capital ventures based in space do not qualify for the 10 per cent investment tax credit. Congress, he said, should extend to all space ventures the special exemption it granted the commercial satellite industry in 1971.

The White House is expected to consider the private sector's shopping list in conjunction with a separate report on space commercialization drawn up by NASA itself but not yet published. Dr James Beggs, NASA's administrator, admitted that publication had been delayed because of internal disagreements but dodged questions about its specific recommendations. Meanwhile, he made it clear that all was not entirely well with NASA's first great commercial enterprise, its shuttle launch business.

Mr Beggs has two major worries. On the one hand, he is under pressure to reduce the price NASA charges for shuttle flights so that private companies trying to make a profit out of the United States' newly-privatized expendable launch vehicles (ELVs) will be better able to compete. On the other, he is afraid the Department of Defense (DoD), which was originally expected to account for a third of all flights in the 12-year life of the shuttle programme, may decide to divert a large proportion of those flights to its own ELV fleet. While officially describing its retention of ELVs as a "backup", DoD, which has yet to fly its first military payload aboard the shuttle, has been hinting that ELVs offer a cheaper and more efficient answer to its needs.

Only if DoD kept its military payloads for the shuttle, Beggs said, would the shuttle operation be able to recover its direct (but not its research, development and building) costs by 1988 or 1989. That was later than expected, because commercial flights began three years later than planned and the market for the shuttle turned out to be smaller than expected. Nevertheless, he said, NASA would start thinking, towards the end of 1986, about the possibility of selling or giving the shuttle fleet to private companies to manage at a profit.

Karl Illmensee

NIH withdraws research grant

Washington

PROFESSOR Karl Illmensee, the embryologist at the University of Geneva accused of falsifying his nuclear manipulation experiments in mice, has now lost his research grant from the National Institutes of Health (NIH). The NIH action follows the finding by an international commission of inquiry in January that errors and discrepancies in Illmensee's records had thrown "grave doubt" upon the validity of the experiments. The commission was unable to substantiate or to dismiss the charges of deliberate fabrication.

Earlier this year, Illmensee's research grant from the Swiss National Fund was revoked. Illmensee has, however, resumed his duties at the University of Geneva.

Illmensee was supported by a $218,000 NIH grant from May 1980 to April 1983. The grant had already been approved for renewal last year when the accusations of data falsification surfaced. On 18 May 1983, Illmensee, at the urging of colleagues who also obtained a now-disputed "confession" from him, wrote to NIH to withdraw a sentence in the grant application that he said had been included by mistake. NIH, concerned about the allegations of fraud and that the withdrawn sentence represented a "major element" of the research proposal, suspended the grant renewal.

After reviewing the commission's findings, NIH decided to terminate the grant application. The decision was taken by NIH director James Wyngaarden on 29 May of this year, but only made public last week after Illmensee had been informed. Wyngaarden also ordered NIH not to award further grants to Illmensee for the same work until he can validate the disputed results. In addition, the commission's findings are to be provided to any NIH review group considering a future grant application from Illmensee.

The NIH officials who studied the commission's report and other available evidence said they could not decide whether the withdrawn sentence in the application had contained "an element of invention", as the commission suggested was possible. But in recommending the actions that Wyngaarden approved, they said that because of "documented deficiencies", the grant should not be made. "In addition, the application was written two years ago and can no longer be considered an up-to-date, state-of-the-art proposal", the NIH officials concluded. The officials also said that no further investigation of the matter by NIH was necessary.

In the withdrawn sentence, Illmensee claimed that a chimaeric mouse had been produced by injecting nuclei from one cell line into mouse eggs of different parentage. Illmensee at first said that the sentence was the result of a typographical mistake made in the haste to complete the application. After being pressed by the commission for an explanation of the actual origin of the chimaeric mouse, Illmensee attributed it to injection experiments involving another cell line; he also sent this revised explanation to NIH. But at the last meeting of the commission, in January, Illmensee said he was no longer certain of that explanation either.

The commission said "it is surprising that Professor Illmensee had to look through his protocols to discover which animal he was referring to in his original NIH application", and concluded that it was impossible to know which "if any" mouse was the chimaera referred to. Illmensee claims that the problem was one of two he has identified.

Neither the commission nor the NIH officials was able to draw any firm conclusions from the accusations of fabrication made by Illmensee's colleagues at Geneva.

Stephen Budiansky

Australian IVF

Orphan embryos

Canberra

LAWYERS in the State of Victoria are at sixes and sevens for lack of legal precedents for dealing with frozen embryos. The issue has arisen because Mrs Elsa Rios and her husband, the parents of two frozen embryos, died in an airplane crash last year, leaving a grown son and an estate estimated at more than $1 million.

Using in vitro fertilization techniques involving donor sperm, an unsuccessful attempt was made by Professor Carl Wood and his colleagues at the Queen Victoria Medical Centre in Melbourne, in June 1981, to implant an embryo in Mrs Rios' womb. She then returned to the United States and the two remaining embryos have been kept frozen ever since. At present, under the common law, an embryo has no rights until it is born, and the State of Victoria will not enact a medically up-to-date legal prescription for questions of custody and inheritance from freeze-thaw embryos until the report of the Waller Committee on the whole subject appears in August.

The Right to Life Association has urged the state's attorney general, Mr Kennan, to appoint a legal guardian to protect the embryos so that they may develop to maturity. Meanwhile, in Los Angeles, twenty-five year old Mr Michael Rios, the son of Mr and Mrs Rios, is reported to have filed for guardianship.

Professor Wood says that the embryos are unlikely to survive because the techniques used at the time they were frozen were not as good as they are now, but no decision will be made about their disposal until after the Waller Committee reports and after correspondence with the executors of the Rios' estate.

Jeffrey Sellar

Childhood vaccine

US plans federal compensation

Washington

IF doctors, pharmaceutical companies and the families of the victims have their way, it will become the job of the US Government to compensate children who suffer damaging reactions to immunization. With the recent announcement by Wyeth Laboratories that it will no longer produce pertussis (whooping cough) vaccine because of the increasing liability burden, pressure has intensified for congressional action to assure that manufacturers will still be willing to produce the vaccines needed and that victims are adequately compensated. Pertussis, polio and measles–mumps–rubella vaccines are all now produced in the United States by single manufacturers.

Lawsuits against the companies are now common. About 60 of the 18 million children immunized each year with the combined diphtheria–pertussis–tetanus vaccine suffer serious long-term brain damage. The usual legal argument of the victims is that the manufacturer or the physician was negligent in failing to inform them of the risks of the vaccine. In some jurisdictions the manufacturer is responsible even when not demonstrably negligent. The companies have refused to discuss publicly the cost of settling these suits.

Under a legislative proposal drafted by the American Academy of Pediatrics and filed by Senator Paula Hawkins (Republican, Florida) and Representative Henry Waxman (Democrat, California), a compensation fund would be created out of surcharges applied to the vaccines. Victims would have the option of suing in the conventional way or of applying to the government for compensation through an administrative procedure. Both the pharmaceutical companies and the Reagan Administration would prefer a bill that prevents victims from suing.

Most of the childhood immunization vaccines used in the United States are purchased in bulk by the Centers for Disease Control (CDC) for distribution to state health authorities. The manufacturers portray their production of the vaccines as a public service, and claim they cannot raise prices to cover the burden of liability without engendering public disfavour. The compensation bill, which would cover all childhood immunizations, is in effect a legally-mandated price increase.

It has been suggested that behind many of the manufacturers' complaints about liability is a dislike of the low profitability of the vaccine business as compared with patentable drugs.

Vaccinations are mandatory before children enter school in the United States. CDC estimate that the pertussis immunization programme prevents 400 deaths per year.

Japanese legislative logjam

Educational reform held up

Tokyo

PRIME Minister Yasuhiro Nakasone has run into unexpectedly fierce opposition to his plans to set up a special commission to reform Japan's educational system. To push the necessary bill through the Diet, together with the bill for "privatizing" Japan's telecommunications monopoly (see *Nature* **308**, 678 and 763; 1984) and some other controversial bills, Nakasone resorted in mid-May to an extension of the 150-day Diet session by a further 77 days. But opposition parties immediately responded with a boycott of Diet proceedings that lasted until mid-June. Debate has only just begun again, and it is still uncertain whether it will be possible to get the bills passed in the extended Diet session.

Moves to reform the educational system — particularly to prevent the university entrance examination hell — are certainly popular enough among the general public and Diet members. They jib only at Nakasone's insistence that it should contain only members appointed by him without the need for Diet approval ("to ensure neutrality"), that it should carry out its deliberations in private ("to avoid outside pressure") and should report directly to himself rather than to the Diet. Under these conditions, the major opposition party, the Japan Socialist Party, believes that the commission will simply be a rubber stamp for Nakasone's personal views on educational reform.

For the universities, Nakasone's ideas of reform are likely to centre on lessening the importance of the entrance examination. At present, university entrance is simply determined by total test scores in school-leaving examinations. Once entry has been won, very little further is expected of students — giving rise to the view of university as a "leisure land".

Nakasone's opinion, as spelled out in his book *A new theory of conservatism*, is that this should be reversed and that universities should be "easy to enter but difficult to graduate from". He also believes that the university system should be far more flexible, for example by allowing students to transfer credits from one university to another — a move that might well help to break down the overwhelming advantage that Tokyo University graduates have in finding jobs. The problem is that much of Nakasone's plea for more "choice" seems to rely on there being more private education, both at school and university levels; but private universities, according to their own just-released white paper, already see difficulties ahead.

With more than a third of all high-school students now going on to higher education, the number of undergraduates will increase massively between 1986 and 1992 when the second "baby boom generation" leaves school. But after that, university entrants will decline sharply. The private universities point out that they need government support if they are to expand for a six-year period to take the extra students and then contract again. At present, the only way they would be able to cope with extra student numbers is by reducing the quality of education. Nakasone's reforms are thus becoming entangled with the level of state support — now declining — for private universities. As it is believed that Nakasone wants to appoint the present head of the private Universities Federation to leadership of the reform commission, the state universities believe that the whole reform plan might end up robbing them of funds.

The most vociferous opposition to the establishment of the commission has come, however, from the school-teachers' union *Nikkyoso*. The union claims a membership of 71 per cent of the primary and junior high-school teachers (though the Ministry of Education says the real figure is 51 per cent) and is left-wing in its views. At its annual convention last week — which required the presence of 2,500 riot police to prevent disruption by right-wing extremists as in the past two years— it decided to have nothing at all to do with the commission. Nakasone had been hoping that he could win support by having a *Nikkyoso* representative on the commission.

The union is naturally worried by the emphasis Nakasone places on "moral education". In March for example, he said in the Diet that "patriotism and the traditional Japanese respect for one's parents should be taught at school". To the left wing this seems too much like a return to the nationalist education that existed before the Second World War, and its members claim that signs of a swing to the right can be seen already.

The contents of school textbooks seem to be being more tightly controlled this year and the Ministry of Education has been accused of using its powers to dilute the facts of the darker side of Japanese history.

For Nakasone, much more rests on the successful passage of the bill than his own personal interest in educational reform. In November, he has to face the bi-annual elections for the Liberal Democratic Party leadership, success in which assures that he continues as prime minister. Despite his popularity abroad and his emergence as Japan's first international statesman, his performance at home has been lacklustre. He will be judged by his fellow party members mainly by his ability to handle the Diet, but in this session he has failed to get a single major bill through (although a measure to increase Diet members' salaries passed with great speed). As well as the educational and telecommunications bills, bills to reform the health system and the electoral system are waiting.

Alun Anderson

Tibetan geology

UK–Chinese joint venture

A COLLABORATIVE research project on the geology of the Tibetan Plateau has been announced by the Royal Society of London and the Chinese Academy of Sciences. It will run for two years from 1 July, with the actual fieldwork taking place in the summer of 1985. Fourteen Chinese scientists and twelve from the West (largely from the United Kingdom), under the leadership of Professors Chang Cheng-Fa, R.M. Shackleton and J.F. Dewey, will spend eight weeks covering more than 1,000 km in perhaps the most inaccessible part of the world. The estimated cost of approximately £350,000 is being shared roughly equally between the two academies, with the Chinese providing the back-up for the expedition.

Scientifically, the project is complementary to the joint French–Chinese investigations in southern Tibet in 1980–83, as a result of which earth scientists now have a better understanding of the mechanisms of formation of the Himalayas and other linear mountain belts. In contrast, the means by which vast areas of relatively undeformed rocks can be uplifted (to an average elevation of 5 km in the case of the Tibetan Plateau) are still obscure, in spite of theories based largely on consideration of the rheology of the Earth's crust. The Anglo-Chinese project should provide the hard facts against which these theories can be tested.

The project involves a 1,000-km traverse from Lhasa to Golmud, on the northern edge of the Tibetan Plateau. Geologically, Lhasa sits on a block representing the southernmost part of Asia, at the junction with the Indian block to the south. North of the Lhasa block, the geology is poorly known, although a number of crustal units have been recognized. Only painstaking fieldwork, building on the reconnaissance surveys of the host nation, will clarify the relationship between these units.

The major results of the French–Chinese work relate to the past 20 million years, although reports of the second expedition in 1981 (see *Nature* **307**, 17–36; 1984) suggested that Tibet may consist of pieces broken off Gondwanaland, which moved north in advance of India, perhaps in successive waves, and eventually collided with Eurasia. The British aim to delve deeper into the past, using predominantly palaeomagnetic and faunal studies, to the earliest separation 150 million years ago in the late Jurassic. The detailed histories of these continental fragments may be better known as a result of the new project.

Negotiations started in 1981 and the programme is regarded as a landmark in the continuing expansion of collaborative programmes between the Royal Society and the Chinese Academy.

Peter Gambles

Dutch nuclear issues

Decisions later

Waalre, The Netherlands

THE Dutch preoccupation with nuclear energy, military and peaceful, will continue for at least another eighteen months. That is the effect of the decision of the Dutch Parliament on 13 June that a final decision on the siting of US cruise missiles in the Netherlands will be made only at the end of 1985. The Netherlands is the only country out of step with the policy of the North Atlantic Treaty Organization (NATO) in this respect.

Never has a subject been discussed so feverishly in the Netherlands. Only the political parties on the right (conservatives and four smaller parties) are in favour of deployment of the missiles, but, according to opinion polls, voters are against the siting plan. On the left, the socialists and three small parties are against, as are the great majority of their voters. The role of the Christian democrats, which together with the conservatives form the government, is especially confusing. Their voters are sharply divided, and they are under heavy pressure from the churches which in advance of 13 June issued declarations asking the government not to install the missiles and in the process offended some church people who hold that the declarations were "too political".

Similarly, the development of civil nuclear power in the Netherlands is on ice, with more than half of the population against it. There are two small nuclear plants (of 60 and 470 MW) now operating, and ten years ago the government proposed building three 1,000-MW plants. But that plan was shelved after a year and a half because of the strength of the opposition, unabated by the oil crisis. But discussion continues, with the churches and the environmental movement playing a prominent part.

Earlier this year (see *Nature* **307**, 405; 1984), it seemed the issue had been settled by the report of the officially organized public consultation which in the previous two years had gathered evidence for its conclusion that further nuclear plants are now necessary and that combined heat and power schemes, in industry and domestic applications as well as wind power, should replace obsolete plants in the 1990s. But now it seems that the government is brooding on plans to expand nuclear capacity by 4,000 MW, and leading newspapers have been complaining that this overrides the democratic consultation the government itself had organized.

The government's plans for nuclear power will in fact be published in September but meanwhile the minister of economic affairs, Gijs Van Aardenne, who was unenthusiastic about the report on nuclear power published in January, does not conceal his enthusiasm for further development, while Prime Minister Ruud Lubbers, in 1974 the minister of economic affairs who put forward the earlier nuclear power plan, is also a supporter.

So the months ahead will be another test for democracy in the Netherlands. Although the debate about the missiles will continue for 18 months, it is barely conceivable that the Netherlands will not follow its NATO partners, despite five years of public demonstrations and social unrest. And the development of nuclear power may follow the same route.

Casper Schuuring

UK science budget

Money needed

THE British Government's advisers on the share-out of the civil science budget have warned Members of Parliament of the dire consequences for the nation's research enterprise unless greater provision is made for science over the next decade.

The House of Commons Select Committee on Education, Science and the Arts, which has started an inquiry into the science budget, heard last week from the Advisory Board for the Research Councils (ABRC), represented by its chairman, Sir David Philips, Dr Walter Bodmer, director of research of the Imperial Cancer Research Fund, and Dr Derek Roberts of General Electric Company Ltd. On the basis of published government expenditure estimates, ABRC predicts that the real value of scientific research is set to decrease by 25 per cent over the next decade.

This stark prediction arises from a number of effects that diminish the value of the research budget, which at first sight is planned to remain roughly constant in real terms. Firstly, according to ABRC, the science vote has had largely to compensate for an 11 per cent cut in recent years to university support of science from the University Grants Committee. Secondly, the Treasury's assumed annual cash increase for the science vote, which decreases from 3 per cent per year to 2.5 per cent per year over the next decade, is fully 2 per cent less than the Treasury's estimated annual increase in the retail price index. This alone would produce a decrease of 17 per cent over the 10 years in real terms.

On top of this, there is the problem of superannuation payments for the increasing number of retired research council staff. And the perennial problem of subscriptions to international organizations still remains. ABRC members emphasized last week their conviction that science had lost out in recent years in relation to other publicly supported activities, while the increasing sophistication of scientific equipment has meant that the same amount of money bought less. And they were disturbed that the government's published expenditure plans include no special reference to the value of science in the economy.

Tim Beardsley

Acid rain

UK in minority of one

THE British reputation for waywardness in the eyes of many Europeans seems unlikely to be improved this week at the World Conference on the Environment, taking place in Munich at the behest of the government of West Germany to discuss ways of combating atmospheric pollution. At the opening session on Monday, Dr Martin Holdgate, chief scientist of the British Department of the Environment, declined to give any firm commitment to reduce British emissions of sulphur dioxide, saying only that a range of measures was being considered that would allow Britain to reduce emissions "in a cost-effective way".

In Germany, acute concern over damage to forests is leading to pressure for drastic reductions in acidic emissions, chiefly sulphur dioxide from power stations and nitrogen oxides. But Dr Derek Pooley, chief scientist at Britain's Department of Energy, said last week he was "convinced that sulphur dioxide was not the major culprit in causing damage to forests".

A major study on acid deposition published last week by the department's energy technology support unit emphasizes the uncertainties. Forest damage appears not to correlate well with sulphur dioxide concentration when dry deposition from local sources is excluded. But above an altitude of 600 metres, which is where most of the damage occurs, photochemically produced ozone can reach sustained and high concentrations. Although no mechanism for ozone damage is known, one suggestion made in the Department of Energy's study is that ozone causes damage to leaf cuticle, which in turn allows leaching of magnesium as the *p*H falls. But Dr Bill Binns of the Forestry Commission, who has made

Cost of impure mice

Washington

A UNIVERSITY of Wisconsin researcher has won an out-of-court settlement with Charles River Breeding Laboratories over a mix-up of mice that the researcher said caused her to waste a year's work and set back her career. Dr Brenda Kahan will receive an undisclosed monetary settlement; in addition, the University of Wisconsin will receive $40,000 from Charles River as compensation for research and overhead expenses of the invalidated research. Two-thirds of that $40,000 will support Kahan's research.

Charles River, a major supplier of laboratory mice, shipped large numbers of genetically impure mice to researchers who believed they were getting a pure strain. The company says it has now corrected the problem. Stephen Budiansky

several studies of forest damage in West Germany, is not so quick to rule out a role for sulphur dioxide. He emphasizes that "occult" precipitation — fog and mist — can be much more acidic than rain and may yet play a part, perhaps in conjunction with other stress factors.

If there is still mystery over the mechanism of damage to trees, the mechanism of damage to fish in fresh water is rather better understood. It seems that elevated levels of inorganic aluminium may be a major cause of mortality. But the chemical changes that will occur in a body of water subjected to acid deposition within its catchment area are greatly affected by the nature of the soil and bedrock, as well as by the type of vegetation present. It is clear that coniferous trees, in particular, can efficiently filter out acids from the air and release these in solution at the next rainfall. The Forestry Commission in Britain is already investigating management practices that may reduce acid release into streams.

Because of the multitude of factors that affect acid depositions, the precise attribution of blame is difficult or impossible. Motor vehicles, for example, along with power stations may be (indirectly) a major source of ozone, through their emissions of nitrogen oxides. But the British contingent at Munich this week will doubtless be able to make much of new estimates published by the Department of Energy of the proportion of British-emitted sulphur dioxide that finds its way to other countries: 3.6 per cent to West Germany, 4.4 per cent to Norway and Sweden combined, while almost 30 per cent stays in Britain.

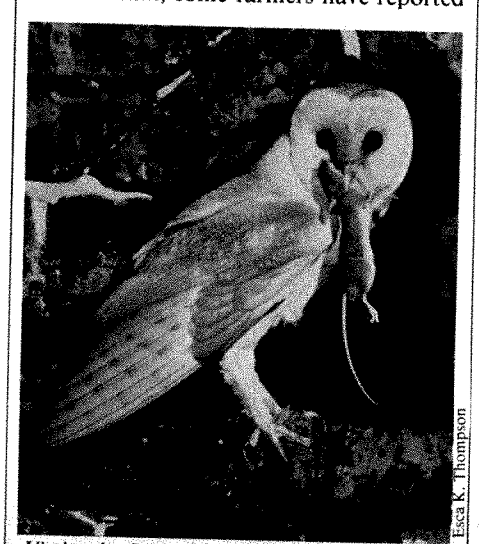
While the British Department of Energy harks on the quantitative uncertainties of acid deposition, the Nature Conservancy Council, which also last week published its views on the matter, takes a somewhat different line. It argues that acidification reduces species diversity in aquatic systems and that the only long-term solution to the problem is therefore to reduce emissions of sulphur and nitrogen oxides. And it is opposed to the policy of liming affected waters on the grounds that the practice will in the long term bring its own undesirable effects.

The British Government seems likely to find itself increasingly isolated over acid emissions. The government is commited to reply before the end of the current parliamentary session to the latest report of the Royal Commission on Environmental Pollution, which urged that the Central Electricity Generating Board should introduce emission abatement measures on a pilot basis. And the Select Committee on the Environment of the House of Commons is shortly to report on the results of its inquiry into "acid rain", which, it may be guessed, will not take a complacent view. It seems likely that political pressure will before long force some government concessions. **Tim Beardsley**

Pesticides

New chemicals under fire

THE latest returns in a two-year survey of the British barn owl population suggest an even greater population decline than had been feared. Ten years ago there were some 4,500–9,000 pairs in England, Scotland and Wales and now, after 18 months of the "Barn Owl Survey" organized by the Hawk Trust, the indications are that the overall decline has been at least 10 per cent, with much greater reductions in many areas.



The only areas where there has been little decline are in Scotland, where the Forestry Commission's activities have provided some additional refuge for the dwindling population. The population estimates, however, are becoming increasingly inexact as the numbers involved get smaller.

The continued decline of the barn owl is thought, says Colin Shawyer of the Hawk Trust, to be a result of the use of new rodenticides by British farmers. Difenacoum and brodifacoum have been growing in popularity in the past few years, steadily replacing warfarin, which is known to be relatively non-toxic to species other than rodents. Brodifacoum is thought to be especially toxic to birds and for that reason has not been given full approval by the Ministry of Agriculture, Fisheries and Food under the Pesticides Safety Precautions Scheme.

Some of the evidence for the effects of the new pesticides comes from Malaysia. On some oil palm plantations, the combination of warfarin and the wild barn owls, encouraged by the provision of nestboxes on poles throughout the plantations, has effectively controlled severe rat infestations. But even on estates where there has been no evidence of warfarin resistance, the new pesticides have been tried. And, says the Hawk Trust, barn owl numbers declined so rapidly that the estate managers went back to the old methods.

In Britain, some farmers have reported to the Hawk Trust that barn owls seemed to disappear from their farms soon after they started using the "second generation" rodent baits. And a veterinary surgeon reported that a barn owl thought to be dying from the effects of difenacoum poisoning was successfully treated by the vitamin K antidote to the pesticide.

Much of the evidence on pesticide toxicity is circumstantial, the Hawk Trust concedes. So the urgent need is for more research on the effects of the new chemicals on non-target species. **Charles Wenz**

Esca K. Thompson

Victims both — a barn owl and prey.

Irreproducing ibis

Tokyo

EFFORTS to save Japan's *Nipponia Nippon* (the Japanese crested ibis or "toki") seem doomed to failure after a romance between two of the remaining birds — Kin (the female) and Midori (the male) — ended in a mid-mating season fight. As Kin is now, in human terms, around 80 years old, the chances of a successful mating next year are thought to be close to nil, although hormones are to be administered in the hope of keeping her in breeding condition.

The toki, a large white bird with a characteristic long downwardly curved black bill and a red face, was a common sight in wet paddy fields and ponds throughout Japan and parts of east Asia as recently as one hundred years ago. But a catastrophic decline in their numbers this century led to their being given special status in Japan in 1934. The war prevented any serious conservation measures, however, and by 1953 only 31 birds remained.

In 1966, special measures were begun but numbers continued to decline so, in 1981, the remaining five wild birds and one captive bird were removed to a breeding centre on the island of Sado — where in bygone days troublesome cadet branches of the imperial family were exiled so that their lines might disappear. Two birds died but hopes rose in 1983 when two of the remaining four birds paired. The female died, however, from a blocked fallopian tube shortly before she laid her eggs.

This year, the romance between Kin and Midori was followed closely but to no avail. As well as being in ripe old age, Kin, having been reared in captivity, apparently did not take too well to Midori, who had led a life in the wild until 1981.

The Sado Island Toki Centre is now to advance research on artificial insemination as fast as possible, but researchers doubt whether practical methods can be developed in time. Hopes for saving *Nipponia Nippon* from extinction now rest largely with the Chinese. In 1980, seven birds were found in China, raising the known numbers there to fourteen — the same as the number remaining in Japan. There have been occasional rumours of sightings in Korea and the southeastern Soviet Union, but none has been confirmed. Alun Anderson

Science and research in India

SIR — You say in your study of science in India that there is no dearth of funds. That is true. Organizations such as ICMR, CSIR, DST and UGC have enormous funds. But how much of this money goes to deserving people? Who, in any case, is deserving? In my opinion, those who deserve research funds are those who have worked in a specific area. Yet as things are, persons who have never seen tribes, never travelled in forest areas and have not worked on any aspect of anthropometry, haemoglobinopathies or population genetics may be allowed to spend 5 million rupees at the expense of investigators with relevant experience.

Last year, I asked a senior official of a major funding agency about this practice. His chilling answer was that "we do not wish even to look at projects costing less than three lacs" (300,000 rupees). He further added that nothing can be done in science these days with one or two lacs of rupees. The truth is that there appears to be no remedy.

In India, there are few first-rate academic institutions when compared with the enormous number of students graduating every year. The general decline of students' interest in higher studies and the mushroom growth of colleges everywhere are unrecognized impediments to India's progress. The tolerance and even the cultivation of corrupt practices in the name of democracy is rampant in all universities and colleges, and in the publication of research work, as discussed in your report.

In my view, four out of five of our universities do not have enough money to support the basic necessities of modern science education, despite modest support from the University Grants Commission. The first reason is the apathy of state governments towards higher education, the second, the outlook of the bureaucrats who control events and, the third, the incompetence of the vice-chancellors. Nowhere in the world have vice-chancellors such an uncertain future (they are replaced so often) and so little power. Even those with vision and ability can be quickly cowed by an under-secretary of the state government on any trivial matter. The exchange and extraction of mutual benefits is rife in the entire university education system. So I would modify *Nature*'s slogan "Excellence in the midst of poverty" to "Excellence against all odds".

My twenty years of teaching experience lead me to conclude that most talent is distracted from research. Many faculty positions, research scholarships and senior fellowships are lying vacant and at least 60 per cent of research scholars leave research fellowships before completion. Nobody wants to acknowledge that part of the reason is the victory of incompetence over ability, mediocrity over genius. In my view, corrupt politicians and officials poison social progress only slowly, but corrupt teachers and particularly scientists can spoil generations. No nation should aim at nurturing mediocrity, whatever its national beliefs.

H. K. GOSWAMI
Department of Genetics,
Bhopal University,
Bhopal-462 026, India

SIR — In my experience Indian scientists have the zeal and energy to succeed, but are handicapped by limited facilities and experience. The majority of institutes in India are sub-standard and producing graduates with limited practical knowledge, as boldly accepted by Dr Subramanian (*Nature* **307**, 206; 1984). One reason for this is that institutes away from the centre suffer step-mother treatment. The centre and the University Grants Commission, the two main funding authorities, are too easily influenced by individuals heading the institutes governed by the centre, or by centrally located organizations who can approach the funding authority directly.

To obtain a research grant in India, one has to be not scientifically orientated, but politically motivated. The system brings non-scientifically minded individuals to the top who are against the return of their scientific compatriots from abroad, and cannot see their local colleagues rising quickly unless they share the credit for their work. Dr Balasubramanian (*Nature* **307**, 321; 1984), sitting in one of the central institutes, has perhaps never had a chance to see establishments which lack the basic necessities to teach or initiate scientific research.

The main problem facing the plan to site an international centre in India (*Nature* **305**, 350; 1983) is that of supply of basic chemicals. Local products are not up to standard, and to import foreign goods, even after going through the red tape, one may have to pay 110 per cent customs duty on essential consumables of research. Sometimes it takes days to get supplies through customs.

Admittedly, India has its nuclear and space programmes to show the world but I do not agree with the claims of Dr Balasubramanian, who is perhaps unaware of the high prevalence of leprosy, tuberculosis and other communicable diseases in the very state where he is working. India must concentrate on educating society and research programmes should aim directly to reduce such human suffering. Many expatriate Indian scientists may wish to go back and the idea of a technology city is very rosy to them, but unless this city is controlled by a scientist with special powers to cut through the bureaucracy of Indian authorities, the city will be a failure. To raise the existing standards of Indian research, direct communication and collaboration with international scientists should be promoted.

SIR — In your otherwise interesting survey, you were not able to give much time to the decaying but historical city of Calcutta, the first capital of British India, and the cradle of modern science in India. You rightly mentioned the late Sir J.C. Bose, the first Indian physicist FRS (1920) and his Bose Institute, founded in 1917 on the model of the Royal Institution of Great Britain. You also mentioned the late Professor S.N. Bose, FRS (of Bose–Einstein statistics) and his institute. But you omitted to mention a giant of Indian science, the late Professor M.N. Saha, FRS, a class-mate of the late S.N. Bose. It was after their joint English translation of Einstein's relativity papers in book form (published by Calcutta University) that Professor Bose was able to continue his work on his chosen subject while at Dacca University.

Professor Saha (the third Indian physicist FRS elected in 1927) made his impact on the world of astrophysics through his famous thermal ionization work in 1920, and became the first Khaira Professor of Physics, Calcutta University in 1921. After a spell at Allahabad University on his return to Calcutta in 1938 Professor Saha installed the first Indian cyclotron at what is now the Saha Institute of Nuclear Physics, inaugurated by the late Madame Joliot-Curie in 1951 with Saha as the founder-director. This institute also built the first electron microscope in India, and now has a thriving biophysics division.

In the premises of the Calcutta University Science College another great Indian scientist, the late Professor S.K. Mitra, FRS, established the Institute of Radio Physics and Electronics.

Third, at the Presidency College, Calcutta, the late Professor P.C. Mahalanobis built the nucleus of the Indian Statistical Institute. It was at Presidency College that the first cloud chamber for cosmic ray studies was constructed by Professor Rajen Sengupta, then a student of the late P.M.S. Blackett.

Finally, at Calcutta today the most active centre for scientific research is the Centre of Advanced Study on Cell and Chromosome Research, directed by Professor A.K. Sharma (in collaboration with his wife Mrs Archana Sharma), at the Department of Botany, Calcutta University. Professor Sharma's new technique for the study of the physical and chemical nature of chromosomes has been widely adopted all over the world.

MONOGRAPHS FROM COLD SPRING HARBOR LABORATORY

MICROBIAL DEVELOPMENT
Monograph 16

Edited by Richard Losick, *Harvard University*
Lucy Shapiro, *Albert Einstein College of Medicine*

This monograph addresses genetic and molecular analyses of cellular differentiation, cell-cell communication, and morphogenesis in prokaryotic and eukaryotic microbes. A special feature is the comparison of similar biological problems posed by very different experimental systems, such as cell division in *E. coli* and *Caulobacter*, spore formation in *Bacillus* and *Streptomyces*, cell-cell communication in *Streptococcus* and *Saccharomyces cerevisiae*, and social and symbiotic behavior in myxobacteria, *Dictyostelium* and *Rhizobium*. The volume conveys the exciting concept that diverse systems share common mechanisms to solve problems inherent in cell differentiation and communication.

August 1984, 328 pp. (approx.), illus., index
Cloth $52 ($62.40 outside US)
Paper $28 ($33.60 outside US)

LC 84-9599
ISBN 0-87969-172-7
ISBN 0-87969-173-5

LAMBDA II
Monograph 13

Edited by Roger W. Hendrix, *University of Pittsburgh*
Jeffrey W. Roberts, *Cornell University*
Franklin W. Stahl, *University of Oregon*
Robert A. Weisberg, *National Institutes of Health*

LAMBDA II, successor to the highly successful *Bacteriophage Lambda* published in 1971, covers the entire field of λ biology, with emphasis on the considerable advances made in the past decade. All chapters have been rewritten to provide an up-to-date reference for workers in the field as well as a coherent presentation of λ biology for graduate students and established investigators in other fields. INCLUDES THE COMPLETE NUCLEOTIDE SEQUENCE OF THE λ GENOME.

1983, 694 pp., illus., appendixes, index
ISBN 0-87969-150-6
LC 81-70528
Cloth $78 ($93.60 outside US)

NUCLEASES
Monograph 14

Edited by Stuart M. Linn, *University of California, Berkeley*
Richard J. Roberts, *Cold Spring Harbor Laboratory*

NUCLEASES is the only volume available to date that gives comprehensive coverage of the entire nuclease field. It provides a single source that covers the properties of the various nucleases, the relevance of those properties to the biological phenomena in which the enzymes participate, and illustrates, where appropriate, their usefulness as reagents. Fully referenced and containing appendixes listing restriction endonucleases, deoxyribonucleases, and ribonucleases, NUCLEASES will be a basic reference source for molecular biologists who use these enzymes as research tools and for phenomenologists who need to know the relevance of nucleases to the biological systems they are studying.

1982, 378 pp., illus., colorplate, appendixes, index
ISBN 0-87969-155-7

Cloth $52 ($62.40 outside US)

THE MOLECULAR BIOLOGY OF THE YEAST SACCHAROMYCES
Monograph 11A & 11B

Edited by Jeffrey N. Strathern, *Cold Spring Harbor Laboratory*
Elizabeth W. Jones, *Carnegie-Mellon University*
James R. Broach, *State University of New York at Stony Brook*

Because of the ease with which Saccharomyces can be manipulated genetically, a large body of data regarding the biochemistry and genetics of yeast has accumulated: the cell and life cycles of yeast have been the subject of extensive mutational, biochemical, and cytological research; and basic questions concerning gene organization, regulation of genetic expression, and moveable genetic elements are being fruitfully approached. All these topics are reviewed and interrelated in the two books that make up THE MOLECULAR BIOLOGY OF THE YEAST SACCHAROMYCES.

Life Cycle and Inheritance:
1981, 751 pp., illus., appendixes, index
ISBN 0-87969-139-5
LC 81-68895
Cloth $86 ($103.20 outside US)

Metabolism and Gene Expression:
1982, 692 pp., illus., appendixes, index
ISBN 0-87969-149-2
LC 81-68203
Cloth $86 ($103.20 outside US)

Set $149.50 ($179.40 outside US)

GENE FUNCTION IN PROKARYOTES
Monograph 15

Edited by Jon Beckwith, *Harvard Medical School*
Julian Davies, *Biogen, S.A.*
Jonathan Gallant, *University of Washington, Seattle*

Dedicated to Luigi Gorini, this book covers developments in the biology of prokaryotes that reflect his research interests in a variety of areas such as gene regulation, ribosome function, translation of the genetic code, and protein secretion from cells. In addition to paying tribute to Gorini's foresighted contributions in these fields, the book provides up-to-date reviews by experts in the field and illustrates how, in a number of areas, prokaryotic studies provide models for the analysis of eukaryotic systems.

1984, 328 pp., illus., index
ISBN 0-87969-164-6
LC 83-15229
Cloth $52 ($62.40 outside US)

New Wild Type M13 Vectors From Pharmacia P-L Biochemicals

M13mp18
M13mp19

- **Wild type phages grow on a variety of host cells**
- **2 new cloning sites: Sph I and Kpn I**
- **Compatible with all M13 primers**

See our 1984 Product Reference Guide for information on our full line of M13 products!

New Tools for Cloning and Sequencing

Pharmacia P-L Biochemicals announces the newest additions to its comprehensive line of products for M13 cloning and sequencing—M13mp18 and M13mp19. Unlike previously available M13 vectors which contain double amber mutations, M13mp18 and M13mp19 are wild type phages. This allows them to be propagated on *E. coli* JM105 which lacks restriction and modification systems, and does not contain the P1 lysogen which was recently discovered in the amber suppressor strain JM103.

This new generation of M13 vectors will be most appreciated by those investigators who are constructing cDNA libraries in M13 or inserting large (greater than 1 kb) DNA fragments which have not previously been cloned in an *E. coli* K12 host. It has sometimes been difficult to obtain full-length clones of large DNA fragments in the previous M13 vectors since the fragments could be degraded by the JM103 host. Use of the JM105 host with M13mp18 and M13mp19 eliminates this problem. As a service to the researcher, our M13mp18/M13mp19 vector kit (product #27-1551-01) is supplied with a culture of JM105.

For more information, contact your local Pharmacia Fine Chemicals/Pharmacia P-L Biochemicals representative or write to one of the addresses below.

Lights hidden under bushels

Geochemists are not alone in failing to make clear the elementary assumptions on which they work. The result is that what they do is under-appreciated.

GEOCHEMISTS, who have a great many achievements to boast of in the past few years, are sometimes their own worst enemies. That is what many innocent readers will conclude from a casual inspection of the rush of articles with which the geophysical literature is now spattered, and which purport to show how, for example, the measurement of neodymium isotopes in some sample of rock can shed light on the past history of the material. The articles on pages 753 and 773, singled out perhaps unfairly as representative of their kind by the mere accident that they are included in this issue, show how unforgiving of their readers' patience the geochemists have become. (If they should protest that they are not alone among specialists in making the assumption that everybody who matters knows what they intend to say, they are merely making the more dangerous assumption that only fellow specialists are likely to be interested).

The underlying difficulty is common in new fields of investigation, perhaps especially in those almost certain to become important. It is then tempting for those with new things to say to work on the principle that the assumptions with which they live day by day are widely appreciated. If indeed, with the passage of time, the novel branch of geochemistry based on the analysis of terrestrial (and other) rocks for the radioactive decay products of rare but long-lived components of the Solar System turns out to be as important as it promises, the result will be that the general readership of the literature will know what the assumptions are. This, to a large extent, is what has happened in the previously daunting field of nucleic acid chemistry, where it is no longer necessary for people to spell out the simple fact that DNA molecules are constructed from four distinct subunits, for example. But if the new geochemistry should be only of middling importance, is it destined to remain more or less a closed book?

That would be, to say the least of it, a pity, which is why, at least for a little while, geochemists should be a little less austere in the way they describe what they have done. It is not that the field is all that unfamiliar. Indeed, it resembles in many ways the pioneering work of F. W. Soddy, in the first decade of this century, in seeking to determine the age of the Earth from the radioactive decay of uranium and thorium.

The essence of that task, successfully completed in the 1930s, is that two principal isotopes of uranium (with mass numbers 238 and 235) ultimately yield as decay products two isotopes of lead (with mass numbers of 206 and 207 respectively). Thorium-232, on the other hand, finishes up as lead-208.

What this implies is that it is possible to infer the length of time for which a rock containing uranium has been undisturbed by a sufficiently accurate measurement of the amount of, say, uranium-238 and of the abundance of lead-206 relative to that of some other isotope of lead known not to be the product of radioactive decay. (Lead-204 is the common standard.) For then the lead-206 found in a sample of the rock will represent both that formed by the decay of uranium-238 and that present at the outset. If the primaeval abundance of lead-206 relative to lead-204 is known (as, for example, from the analysis of rocks containing lead but no uranium), it requires merely simple subtraction to discover how much lead-206 has been formed by the decay of uranium-238.

The techniques now being exploited with such profit by the geochemists are in principle no different. Neodymium-143 is formed by the alpha-decay of samarium-147 (with a half-life of more than 100,000 million years) and strontium-87 from rubidium-87 by beta-decay (with a half-life of nearly 50,000 million years). Relative to other isotopes of neodymium and strontium, the excess amounts of the radiogenic daughter elements in some sample of rock are simply related to the amounts of the radioactive isotopes originally present and to the length of time which has elapsed. The conventional standards for comparison are the isotopes neodymium-144 and strontium-86 respectively.

Much of the confusion that attends the use of these techniques in geophysics stems from the recognition, in itself a discovery of great importance, that the elements involved, the radioactive parents and their daughters, have beeen repartitioned among the several components of the Earth's layer structure during geological history, not all of it Archaean. Both rubidium and strontium, as chemical elements, are more abundant in continental crust than in the mantle from which the continents were formed, but the relative concentration of rubidium is greater than that of strontium (by factors of perhaps 70 and 20 respectively). With samarium and neodymium, by contrast, the daughter tends to be more highly concentrated than the parent.

Chemists are quick to point out that this redistribution of material is largely a function of the radii of the ions of the elements involved. (By chance, uranium and lead are concentrated in the continental crust relative to the mantle by roughly the same degree.) Whatever the mechanism of this process, what emerges is that the abundance of strontium-87 (relative to strontium-86) is greater in the continental crust than in the mantle, while the abundance of neodymium-143 (relative to neodymium-144) is less than in the mantle.

The interpretation of the ratios actually measured is complicated by the difficulty of knowing the full history of the material concerned. In attempts to infer the age of the Earth from measured abundances of uranium isotopes and the corresponding isotopes of lead, it is sufficient to search for the oldest rocks and to compare the results of abundance measurements with those obtained from meteorites. By contrast, the chief utility of the use of the newly-measurable isotopes is that they may be used to trace the comparatively recent history of the Earth's surface layers, continental crust and ocean floor alike, in which case there can be no fixed assumptions about the abundance of the isotopes in the starting material.

This does not, however, prevent practitioners from talking of "anomalies". The reference point is usually some notional composition of primaeval material but is hardly crucial, since only differences of abundance bear on the processes by which material has most recently been repartitioned. Eventually it should also be possible to construct a kind of historical record of the average abundance in the mantle of the isotopes involved, at least if the mantle is crudely homogeneous.

All this, of course, is commonplace among geochemists. But now and again, it would do no harm if they were to remind their readers that neodymium-143 is the product of the radioactive decay of samarium-147, or that lead-206 is the product of uranium-238. Certainly they should be more forgiving of their readers' almost certain ignorance of the importance of these isotopes as tracers of the fractionation of terrestrial material. To fail to make these concessions is to underplay an exciting field.

John Maddox

Fisheries

Genetics, dynamics and politics

from John H. Lawton and Robert M. May

MARINE fish stocks, broadly interpreted to include such taxonomically disparate beasts as whales, shrimp, crabs, shellfish and squid, together with fish in a strictly zoological sense, constitute one of the world's great biological resources. Attempts to understand, conserve and exploit resources confront marine biologists with a number of intriguing theoretical and practical problems, often made more difficult by political and economic constraints operating on the fishery. A recent Dahlem Conference* grappled with a range of such problems.

Some of the biological problems confronting fisheries managers have implications for evolutionary biology and ecology far outside their primary concerns of maximizing profits and minimizing the risks of overfishing. Two, namely fishing as a major selective force acting on the genetic composition of fish stocks and the problem of how best to construct tractable models of complex multi-species fisheries, seem particularly important.

Often, though by no means always, fishing a previously unexploited stock leads to faster growth and earlier breeding of the surviving population[1]. Predictions of yield, profits and the population's capacity to withstand exploitation hinge on a sound understanding of such changes in demography under exploitation. The changes can happen quickly, and have generally be attributed to the fact that as stocks are fished down, food supplies per individual increase, leading to faster growth and earlier maturity. However, an explanation based on such density-dependent effects in the population dynamics is not the only possibility; the response could also be genetic; if, as seems likely, growth rates and age of maturity are genetically determined, and there is heritable variation for these traits within the population, then fishing represents a massive novel selection on the population. Individuals that grow faster and/or mature earlier may be at an advantage in the fished population because, other things being equal, they are more likely to reproduce before being caught. Other mechanisms possibly responsible for the observed demographic changes include alteration in environmental variables that more or less accidentally coincide with changes in fishing intensity, or even that apparent changes may be artefacts of the way the data are gathered.

Although it is difficult to distinguish genetic from other explanations for changes in the vital rates of exploited fish stocks, useful tests may come from situations where fishing, paradoxically, leads to a reduction in growth rates and to an increase in the mean age of fish. This apparently happened in the case of the Lesser Slave Lake Whitefish, *Coregonus clupeaformis*[2]; such changes are not easily accounted for by responses in population dynamics to fishing, but may be due to heavy selection of gill nets on large rapidly-growing genetic variants in a species where reproduction is strictly determined by age and not by size[2].

In most populations we might expect to see both population-dynamic and genetic responses to fishing, working either in concert or in opposition to one another to influence the demography of the exploited population. The consequences are important for managers wishing to predict the long-term dynamics of fish. But over and above all these practical considerations, evolutionary biologists, interested in life-history strategies[3], should pay more attention to the possibility that fish life-histories can evolve in response to fishing.

A second area where essentially practical problems of fisheries management may have wide theoretical repercussions centres on how best to construct tractable models of complex multi-species communities. Not unexpectedly, the fisheries that are most rich in species are in tropical waters. For example, off the Senegal–Mauritanian coast as many as 174 species are involved in the demersal fishery; a single trawl haul can contain 20–50 species. Official statistics for this area tend to group catches into commercial categories, but still 48 species are identified in the records for Senegal[4]. Classical fisheries models, based on single species, are obviously no use under these circumstances. However, detailed simulation models involving all the commercial species and their food supplies are not a solution either. Even if the data were available, the sensitivity of the very complex models to errors inherent in estimating the snowstorm of parameters necessary for their construction makes them unworkable.

Simplified models are much less sensitive to parameter variation, but the problem is how to simplify them. Grouping species into manageable sets could be done in several ways, for example taxonomically, or by habitat, or by commercial value. At the moment, there are no reliable theoretical rules to guide such endeavours, and the best solution must, in any case, depend on the circumstances and the objectives of the modeller. One promising approach may be to use some combination of body size and habitat. Even the very complex West African fishery can be grouped into a limited number of species assemblages on the basis of habitat, specifically water depth and bottom type[4]. Within habitat divisions, grouping individuals by body size irrespective of taxonomy may not seem the most obvious thing to do, but since body size has rather predictable effects on an animal's vital rates[5], the approach has much to commend it. In the long term, successful predictions using aggregated models of complex multi-species fisheries could have profound implications for ecologists struggling to make sense of, and model, equally complex communities in other habitats.

Of course, even classical 'single-species' fisheries, such as cod or herring in the North Sea, or anchovies of Peru, are members of complex communities, providing both food and shelter and harbouring enemies and competitors[6]. A broader 'ecosystem' perspective on even a simple single-species fishery may suggest ways of using indicator species — sea-birds, for example — to monitor the health of fish stocks. There was disagreement among participants at the Dahlem Conference about the feasibility of such an approach, but it should not be dismissed out of hand. Certainly, reduced breeding success, or failure of sea-bird colonies to recover from a natural disaster that in the past has presented no problems, could be a clear indication that all is not well with the birds' food supply.

Another major theme of the meeting was the way unpredictable environmental events can lead to significant fluctuations in fish stocks, and thus to uncertainty in the catch from year to year, or over longer periods. In particular, it can be that the rates at which new recruits are produced are affected differently by some kinds of environmental fluctuations when the stock density is relatively low (as a result of heavy exploitation) than when it is relatively high (in its pristine state); this, in turn, may result in the yield becoming significantly more variable as fishing pressures increase. As observed at Dahlem[1,4] and before[7-9] such effects can lead to situations where it is better to fish less intensely, diminishing the fishing effort below that estimated to

* The Dahlem Conference on 'Exploitation of marine communities' was held in Berlin on 1–6 April 1984. The proceedings will be published as a book by Springer-Verlag, later this year.

give the maximum average yield in order substantially to reduce the severity of fluctuations in the yield. Such trading of risk against maximum possible return is more familiar in the management of university endowments.

In this general context, the conferees sought to identify some tentative patterns in the degree to which different kinds of fish stocks exhibit such variability. One suggestion was that species high in the food web tend to live longer, which in turn tends to make their population densities relatively less variable[10]. Another suggestion was that tropical species tend to live longer than ecologically similar temperate ones, again tending to make for relatively steadier dynamics[10], although for terrestrial insects Wolda and others have concluded that tropical populations do not fluctuate significantly less than temperate ones[11,12]. A more specific suggestion, tied to life-history details, is that species such as plaice or sole, which make their living on the essentially two-dimensional world of the sea floor, are thereby in a less chancy environment, and that this is why their stocks appear to fluctuate less than do many pelagic fish such as herring[13].

Troadec (Institut des Pêches Maritimes, Nantes) and others emphasized that fluctuations in the processing and marketing of fish are every bit as worrisome as fluctuations in the biological stock or in the catch. For fisheries that are relatively predictable, it may be desirable to bring industrial capacities for treatment, packaging and marketing fish products close to the minimum required to exploit the resource at some set average level, allowing for some fluctuations but not for gross overexpansion in good times and collapse in bad ones. This is easier said than done, but in the absence of such efforts at control then all factors — from biological harvesting to marketing — can create lags and inertia that end up greatly amplifying such fluctuations as are inherent in the system. Conversely, for fisheries that are intrinsically highly variable (either in yield or in species composition), as some pelagic fish seem to be, it may be best to aim for flexibility in harvesting, processing and marketing, given that 'cashing in' on the good years will have little repercussion on future biological events. Tidy though such a dichotomy is in principle, we really need to understand multispecies effects better before we can implement the ideas with any confidence[10].

As emphasized by Clark (University of British Columbia) and others in discussion, the real uncertainties in fish catches and marketing are further complicated by psychological aspects of uncertainty. Thus, for example, the macho acceptance of risks by some kind of fishermen can confound policies based on conservative rationality. Despite all the biological, economic, political and psychological problems that beset the management of both single-species and multispecies fisheries, the general tone of the final discussion was, we think, a cheerful one: our current understanding, though very far from complete, is probably enough to provide a basis for giving good advice for the management of most fisheries, at least in the short run. But in the long run, as stressed by Shepherd[14], in most cases we probably need kinds of information (knowledge of the absolute magnitude of stocks, and a full understanding of factors determining recruitment and mortality) that is not currently available. □

Materials science

Superlattices, superdislocations and superalloys

from Robert W. Cahn

SUPERALLOYS, the key materials for making turbine blades and discs in jet engines, have been steadily improved since the introduction of the wartime 'Nimonics'; maximum service temperature has been progressively raised and engine efficiencies have been improved in parallel. But the available means for maintaining this rate of improvement are now more or less exhausted short of a radically new approach. Just such an approach is offered by some recent 'pure' research on one constituent phase of all superalloys, the nickel-based 'gamma prime' phase.

The diverse family of superalloys is, in essence, based on a single structural principle. They consist of a dispersion of particles of a coherent 'gamma prime' phase — Ni_3Al in its pure form but generally containing Ti and other elements — within a gamma phase, a matrix of nickel containing various solutes. Gamma and gamma prime are coherent in the sense that the lattices match up so closely that their interface is of very low energy; this in turn implies that the gamma prime particles are highly stable against growth. The other vital characteristic of these alloys is that the gamma prime phase is atomically ordered; in other words, it consists of a superlattice, like the much-studied Cu_3Au alloy, but unlike that alloy the order persists undiminished right up to the melting temperature. All sorts of other microstructural features have been introduced to add to the excellent creep resistance of superalloys at high temperatures, but the above features are the crucial ones.

Gamma prime has a remarkable property: whereas all ordinary alloys weaken as they are heated, the strength of an experimental alloy of pure Ni_3Al gamma prime phase increases as it is heated, almost until it melts. Plainly, this property is of central importance in determining the good creep resistance of superalloys as a class. Such anomalous mechanical behaviour as Ni_3Al and a number of other A_3B phases, such as Ni_3Ti. Much ink has been spilt in attempts to interpret this anomaly. It is known that dislocations move through highly ordered alloys in pairs, collectively termed 'superdislocations'. In a very stably ordered alloy these pairs of dislocations, which are joined by strips of disordered material called antiphase domain boundaries, are so close together that they can twist and turn and escape on to abnormal lattice planes. It is the twisting and turning that leads to the anomalous mechanical behaviour; at least, this is the current orthodoxy.

In superalloys cast in the normal way, the individual gamma prime particles — typically less than 1 μm across — each consist of a single domain. Consequently, it has not been possible to manipulate their domain size, which is an important variable in the general theory of the mechanical behaviour of ordered alloys. This situation has recently been changed, however, by research carried out in the Japanese laboratory at Tohoku University, where so much important metallurgical research has been done. An important paper from this group examines the behaviour of superalloys ultrarapidly quenched from the melt (Inoue, A., Tomioka, H. & Masumoto, T. *Met. Trans.* **14A**, 1367; 1983). At cooling rates approaching 10^6 K s^{-1}, there is not time for proper ordering and the phase consists of fine antiphase domains around 50 nm in size. The result, for a variety of phases of type Ni-Al-X, where X is Cr, Mo

or Fe, and the alloys consist entirely of gamma prime, is that both the strength and the ductility of the alloys are enhanced, whereas usually one of these improvements must be bought at the expense of the other. Once the quenched alloys are annealed, the domains grow (the state of order is improved) and the alloys become both weaker and less ductile. Unfortunately, Inoue *et al.* did not test the variation of the strength of the fine-domain structure with temperature; it is now important to know whether that is also subject to anomalous behaviour.

Another recent Japanese paper, from Tokyo (Ochiai, S., Oya, Y. & Suzuki, T. *Acta metall.* **32**, 289; 1984) reports the extent to which third metals can be dissolved in the gamma prime phases Ni_3Al, Ni_3Ga, Ni_3 and Ni_3Ge, and the superlattice site preferred by the third metal; these features are related to atomic size ratios and to the various bond strengths. In the present context, it is of particular interest that two of the authors of that paper previously studied the anomalous mechanical behaviour of a number of gamma prime phases (for example, Pt_3In and Pt_3Sn), finding, in general terms, that the more stable the ordered phase the more pronounced the anomalous strengthening with rise of temperature (Suzuki, T. & Oya, Y. *J. mater. Sci.* **16**, 2737; 1981). This seems consistent with the orthodox explanation of the anomaly, outlined above.

It should now be possible to answer some very interesting questions by rapid-quenching experiments on such 'model' gamma prime phases, both binary and ternary. First, does the size of the microdomains produced by quenching scale with the stability of the ordered phase? Second, how do the mechanical characteristics of these phases, particularly their anomalous behaviour, react to the introduction of imperfect order — that is, small domains? Finally, what are the consequences of the gradual healing of imperfect order by subsequent heat treatment? In this connection, it is probable that the domain size in a ternary alloy series based, say, on Ni_3Al or on Ni_3Ga, will be a function of concentration of the third element, and if so, it will be illuminating to see how the mechanical anomaly varies across a ternary series prepared by melt-quenching.

In this way, the curious mechanical characteristics of gamma prime can perhaps be related to the mechanical behaviour of imperfectly ordered phases such as Cu_3Au or FeCo, on which a large literature exists. In general, the strength of such alloys peaks at an intermediate degree of order, but the dependence of ductility on the degree of order has not been studied. The introduction of rapid quenching, it seems, may re-open the study of the mechanical characteristics of ordered phases, which has been in the doldrums of late. □

Blood cell development

The message in the medium

from T.M. Dexter

EVERY minute of life, a human must produce an average of about 150 million red cells and 120 million granulocytes, which constitute the majority of white cells. Mature haematopoietic cells, such as these, are derived from several types of progenitor cell, each committed to develop into only one or two cell lineages; but all progenitor cells take their origin from the same 'stem' cell. The control of this developmental process — the regulation of 'production quotas' and of 'quality control' — is thought to reside in a family of haematopoietic growth factors. To a great extent, these growth factors are still ill-defined molecules present either in serum or in 'conditioned medium' — the fluid left after the growth of certain cells *in vitro*. But the techniques of molecular cloning are beginning to define the factors. One yielded to that approach earlier this year[1,2]; Gough *et al.*, from Melbourne, report their success with a second factor on page 763 of this issue[3]. The emerging data are bound to create widespread interest and excitement for developmental biologists.

The significance of these findings is best considered in the context of the overall process of the formation of blood cells which starts during embryogenesis with the laying down of a relatively small number of pluripotent haematopoietic stem cells. By virtue of their ability to self-renew, sufficient stem cells are generated not only to maintain their population throughout adult life but also to produce, by differentiation, the progenitors of all haematopoietic cells. It is obvious that the maintenance of haematopoiesis requires that a balance be maintained between self-renewal and differentiation. If too many stem cells were to differentiate, the system would soon undergo a decline; if too few differentiate, there will not be sufficient input into the progenitor cell compartment to meet the demand.

The progenitor cells, the immediate progeny of the stem cells, are recognized by their ability to undergo proliferation in soft-gel media *in vitro* to produce colonies of mature cells of the appropriate lineage. For many years it has been known that the survival, the proliferation and the development of these 'colony-forming' cells *in vitro* requires the continuous presence of specific growth regulatory molecules.

The story began with independent observations that colonies of granulocytes (neutrophils)[4] or macrophages[5] would develop in soft agar, provided that feeder cell layers or conditioned medium were present in the culture. Since then, modifications of this technique have provided the conditions in which the other three myeloid progenitor cell types — those that spawn red blood cells, platelets a eosinophils — can be stimulated to fo colonies (reviewed in ref.6). In all cas colony development requires the prese of ill-defined growth factors or 'colo stimulating factors'. Not surprising many workers have formulated (and still formulating) their own pet names these factors, causing much confusi both within and outside the field developmental haematology. Also, th has been a considerable variation in sources of the factors, the concentratic of factor used and the source of the resp ding cells (marrow, spleen, fetal live Because of this, it has been impossible determine, for example, whether the co mon progenitor of both granulocytes a macrophages responds to only one grow factor or to a family of growth facto Paradoxically, this initial lack of agre ment and standardization among t groups involved has been of some benef since several different and specific grow factors have been discovered as a result the variety of starting materials.

The use of conditioned media facilitate the growth of haematopoiet progenitor cells is still widespread. In th last five years, however, many of the acti growth factors have been purified to a parent homogeneity, enabling a clearer pi ture to emerge of their biological activiti and target cells. The properties and th nomenclature (still confusing) of some the growth factors for myeloid progenit cells are summarized in the table.

A simple interpretation of the data is th haematopoietic cell development regulated by a (limited) series of growt factors which are progressively restricted i their biological activities and target cell Thus, the recently cloned[1,2] growth facto IL-3 (for definition of abbreviations use see the table legend) is indifferent to lineag — promoting growth and development o all the different myeloid progenitor cell Moreover, it facilitates self-renewal o pluripotent (CFU-S) and multipoten (CFC-Mix) stem cells, and can 'immor talize' granulocyte precursors and mas cells *in vitro*. GM-CSF is more restricted stimulating both proliferation an development of only granulocyte macrophage and eosinophil colony forming cells and the proliferation, but no the subsequent development, of the CFC Mix and the red cell progenitor, BFU-E; t my knowledge, there is no evidence th GM-CSF stimulates self-renewal of any o these cell populations. The growth factor G-CSF and M-CSF are even more restricte in their activities.

Firm evidence that two of these growth factors are indeed quite distinct species

comes from the new data of Gough *et al.*[3], who have cloned and sequenced the cDNA of GM-CSF, and deduced the amino acid sequence of GM-CSF from the cDNA sequence. Also of significance is their observation that GM-CSF is encoded by only one gene; hence the reported differences in GM-CSF from different tissues probably reflect post-translational modifications. An intriguing additional finding by the Melbourne group is that, although they show no structural similarity, IL-3 can compete with GM-CSF for binding to its receptor (A.W. Burgess, personal communication). It seems, then, that some multipotential stem cells, progenitor cells and IL-3-dependent cell lines have both IL-3 and GM-CSF receptors; that IL-3 can bind to both receptors, but that GM-CSF can bind only to its own receptor. Since these two regulatory molecules appear to have quite distinct roles vis-a-vis self-renewal, proliferation and development, it may well be that the outcome of a response depends upon the relative concentrations of the two regulators and the number and accessibility of binding sites. Development may be further regulated by the lineage-restricted molecules G-CSF, M-CSF and erythropoietin.

The problems have by no means all been solved. Nonetheless, the way in which the haematopoietic cell growth factors interact to promote self-renewal, proliferation and development can now be studied in some detail *in vitro*. It will be just as important, of course, to determine whether such growth factors have a role *in vivo*. In the adult, haematopoiesis occurs in the marrow in association with a stromal cell meshwork. Evidence indicates that the stromal cells are not passive bystanders but themselves influence haematopoietic cell development, presumably by supplying the necessary cell matrix and diffusible molecules[7]. So far, it has been difficult to ascribe to IL-3 or GM-CSF a role in this process — the availability of cDNA probes should now help to resolve this problem.

The question of whether inappropriate expression of these growth factors has a role to play in leukaemogenesis can also now be addressed using the cloned cDNA. With this recent work, haematology has entered a new and exciting era. □

BIOLOGICAL ACTIVITIES AND TARGET CELLS OF MYELOID GROWTH FACTORS

The table is compiled from published data and is meant not to be a comprehensive survey of the field but to serve as a reference point for the various names and activities of the growth factors. + indicates a positive response, — a negative response, and ? an equivocal or controversial result. ND, not determined. The full names corresponding to the growth factor acronyms are as follows: IL-3, interleukin-3; BPA, burst-promoting activity; HCGF, haematopoietic cell growth factor; CSF, colony-stimulating factor; MCGF, mast cell growth factor; PCSF, P-cell-stimulating factor; GM-CSF, granulocyte/macrophage colony-stimulating factor; MGl-lGM, macrophage/granulocyte inducer—granulocyte macrophage; G-CSF, granulocyte colony-stimulating factor; MGl-2, macrophage/granulocyte inducer-2; D-factor, leukaemia cell-differentiation-inducing factor; GM-DF, granulocyte/macrophage and leukaemic cell differentiation-inducing factor; M-CSF, macrophage colony-stimulating factor; MGl-lM, macrophage/granulocyte inducer—macrophage specific; CSA, colony-stimulating activity; CSF-l, colony-stimulating factor-l. The target cells are: CFU-S, colony-forming unit—spleen, multipotential stem cells; CFC-Mix, colony-forming cell—mixed, a multipotential stem cell with the ability to form mixed myeloid colonies in soft agar; BFU-E, burst-forming unit—erythroid, a primitive erythroid progenitor cell assayed *in vitro*; GM-CFC, granulocyte/macrophage colony-forming cell which has an ability to form G (granulocytes), M (macrophages), or mixed colonies *in vitro*; Eos-CFC, eosinophil colony-forming cell; Meg-CFC, megakaryocyte colony-forming cell. BFU-E, GM-CFC, Eos-CFC and Meg-CFC form part of the so-called 'committed' progenitor-cell compartments.

Data analysis

The maximum entropy method

from John Skilling

MAXIMUM entropy is a remarkably powerful and general technique of data analysis. It can be used to sharpen up out-of-focus photographs (as in Fig. 1), to make maps of the radio sky, to generate images from medical scanners, to calculate spectra, to reconstruct electryn densities in a crystal and even to determine the positions of fuel rods in a nuclear reactor cooled with liquid sodium. It claims to be applicable whenever one needs to estimate a single vector of proportions $p = (p_1, p_2, \ldots, p_M)$ from seriously incomplete data, which could be fitted equally well by many different vectors. It claims to ignore what the proportions represent, which is why it can be applied to so many different inference problems. Maximum entropy always selects the simplest possible result, containing the bare minimum of structure needed to fit the data. Spurious detail is reduced as far as possible, which doubtless accounts for the practical success of the method.

The principle is always the same: one maximizes the entropy $S = -\Sigma_i p_i \log p_i$ subject to whatever constraints are imposed by the data. The theoretical basis of the method has often been less clear than the practical results however. Now papers by Shore and Johnson (*IEEE Trans. Inform. Theory* **IT-26,** 26; 1980 and **IT-29,** 942; 1983) and by Tikochinsky, Tishby and Levine (*Phys. Rev. Lett.* **52,** 1357; 1984) are making the justification for the maximum entropy method both clear and compelling.

Historically, the use of maximum entropy in data analysis has often been justified by supposing that the proportions were quantized, so that $p_i = n_i/N$. If N quanta were placed 'at random' into M available locations, the relative frequency of sets of occupation numbers n would be degeneracy $N!/\Pi n_i!$, which is equivalent to $\exp(NS)$, at least if N is large. Thus maximum entropy would be the same as maximum degeneracy, which could in turn be identified with maximum probability. Partly because of the dubious status of N and the quantization, this derivation has never been entirely convincing to scientists at large. An alternative justification has been to eschew quantization and identify S directly with (minus) the Shannon information content of p, considered as a vector of probabilities. One can then talk about minimizing the configurational information of p; but once again the rationale has not proved universally convincing.

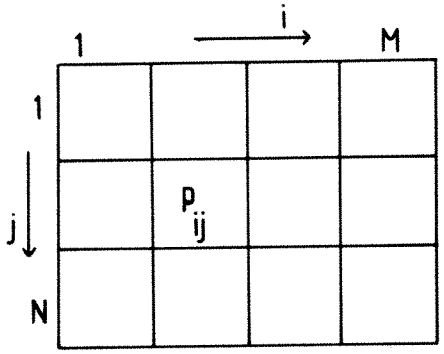

Fig. 2 For definition of i, j, M, N and p_{ij}, see text.

The new analyses reach a deeper level that bypasses the earlier derivations, and show that maximum entropy is the only consistent selection procedure. Let us start with Tikochinsky *et al.*, and with a diagram (Fig. 2), in which p_{ij} represents the probability of outcome i when performing experiment j. Tikochinsky *et al.* consider 'reproducible' experiments in which p_{ij} is independent of j, and in which incomplete data are acquired in the form of linear combinations $\langle A \rangle = \Sigma_i A_i p_i$. Because the data are incomplete (fewer than M combinations), the values of $\langle A \rangle$ do not fully determine the values of p. But if we must select just one single result, how should we go about it? Suppose the experiment is repeated N times. We are at liberty to treat each experiment independently. In this case, our selection algorithm (whatever it might be) will choose the same proportions p_i for each experiment j, and these could be combined to give an overall distribution P_i for the outcomes i after the N repetitions. We are also at liberty to treat the whole as one large experiment, in which case our selection algorithm will immediately produce an overall distribution Q_i. Tikochinsky *et al.* point out that we must surely require $P_i \equiv Q_i$ if data from reproducible experiments are to be combined consistently.

Repeating or averaging an experiment does not change its outcome, and it should not change the selected result either. In ten short equations, Tikochinsky *et al.* proceed to prove that the consistency requirements is satisfied if, and only if, the selection algorithm is maximum entropy. In a brilliantly simple way, entropy emerges as an elementary consequence of consistent reasoning.

The consistency approach can be taken even further. Tikochinsky *et al.* couch their analysis in terms of probability distributions, but it often seems a little artificial to have to identify a set of physical proportions with a set of probabilities of outcomes of a random experiment. Proportions and probabilities are, of course, isomorphic, but why should we need to introduce the idea of randomness at all? And why should we need to restrict ourselves to linear data? The answer to both questions is that we need not.

Let us return to Fig. 2, but let p_{ij} now represent the proportion of the total observed quantity assigned to cell i, j of the $M \times N$ array ($\Sigma_{ij} p_{ij} = 1$): we could be considering a two-dimensional digitized picture. Suppose that the data are some arbitrary functions $U(u)$ and $V(v)$ of the marginals $u_i = \Sigma_j p_{ij}$ and $v_j = \Sigma_i p_{ij}$. We are at liberty to ignore the 'north–south' v-structure, and use our selection algorithm to choose an 'east–west' distribution u_i which fits the data U. Similarly, we can select a north–south distribution v_j which fits the data V, without reference to U. Finally, we are at liberty to use all the data, U and V together, to produce immediately an overall distribution p_{ij}. We must surely require $p_{ij} = u_i v_j$ if data from independent experiments are to be combined consistently. North–south data must not interfere with east–west structure, and vice versa. This will be the case if, and only if, the selection algorithm is maximum entropy. Again, entropy emerges as an elementary consequence of consistent reasoning.

This is the derivation of entropy which we at Cambridge now prefer (see our rigorously informal presentation in *Indirect Imaging* ed. Roberts, J.A., Cambridge University Press; 1984, a more mathematical account of which has been

Fig. 1 What maximum entropy techniques can do for car-spotters, including the police.

submitted to *Acta crystallogr.* A). We obtained our derivation from Shore and Johnson's papers, in which the notion of independent dimensions is refined to a requirement of system independence, and the whole treatment is given a proper axiomatic foundation. Shore and Johnson give four axioms — uniqueness, invariance, system independence and subset independence — which must be satisfied by any consistent selection algorithm. In careful and formal work that is remarkably similar to an axiomatic derivation of Shannon information, Shore and Johnson derive the entropy formula, generalized to $S = -\Sigma_i p_i \log(p_i/m_i)$ to allow for a possible prior model m. Although they describe p as a probability distribution, this is unnecessary; their work applies equally well to any distribution of proportions, and the technical words 'probability' and 'information' need never appear.

These ideas justify the fundamental claims made for maximum entropy in data analysis, and it is clear that we need not quantify our preference for the maximum entropy selection by anything other than the numerical value of S. It is sufficient to know that we must use maximum entropy — or lay ourselves open to the charge of inconsistency. Let's get on with it. □

Palaeobotany

Early evolution of leaves

from J.B. Richardson

THE origin and evolution of leaves was a major event in land plant evolution and must have affected all other life on land. Much remains to be learnt, however, of when they first appeared and how they evolved. Fossils described on page 785 of this issue by Gensel[1] confirm what had already been suspected from compression fossils from the Gaspé Peninsula: by the end of the Lower Devonian, vascular plant evolution was quite advanced with complex forms present. The presence of divided non-laminate leaves at the end of the Lower Devonian is already documented[2] but Gensel[1] describes changes in anatomy in a lateral branch system suggestive of the early evolution of a megaphyll — a laminated leaf with a complex pattern of venation.

Did leaves arise as Zimmermann suggests in his telome theory[3], through evolutionary overtopping, planation and webbing? A telome is the most distal dichotomy of a plant. Overtopping describes what occurs if one branch of the dichotomy develops more than the other. The overtopped branches would diminish in size, eventually tranforming the equal dichotomies into a main stem with lateral branches. Planation describes the change from a three-dimensional arrangement into a single plane of neighbouring telomes. Webbing, the joining of tissues between the lateral branches of the planar telomes, would result in the familiar lamina (leaf-like structure) with dichotomous venation.

This is what Zimmerman proposed but how is the theory testable? One of the restraints on evolutionary hypothesis is the geological record. Do these morphological features appear in the geological succession in the order demanded by the theory? The answer is both yes and no. Simple dichotomously-branched axes have been recorded in the mid-Silurian (Wenlock)[4], while by the late Silurian, rhyniopsids, with a similar appearance, were common but not diverse. Overtopping was present in the early Devonian (Lower Gedinnian)[5]. At that time there was considerable diversity of the rhyniopsids, and zosterophylls, distinguishable from the rhyniopsids on the basis of lateral sporangia, were present[6]. Later, during the Siegenian, the zosterophylls diversified[7] and the trimerophytes, such as *Dawsonites*, appeared. Later still, in the Lower Emsian of Belgium, a similar flora along with several *Psilophyton* spp. was present[8] and work by Andrews indicates a high diversity of plants at that time (see *inter alia* ref.9). Trimerophytes in the Emsian exemplify overtopping and reduction of laterals; as Stewart[10] states "Trimerophytopsida exhibits almost every branching pattern to be found in megaphyllous vascular plants". Thus, as re-emphasized by Gensel's paper, Zimmermann's leaf-forming processes, apart from planation and possibly webbing, had happened by the late Lower Devonian and much of the geological record supports the telome theory on the origin of megaphylls.

Zimmermann derived a great variety of leaves and leaf-like structures, including microphyllous 'leaves' of the lycopsida, from a rhyniopsid-like ancestor. Bower's enation theory[11] is an alternative proposal for deriving microphylls — small leaves with a single central vein. In the telome theory, the microphylls arise by reduction of bunches (trusses) of telomes. Bower's theory is that bumps (enations) emerged from the surface of the stems. As these enations extended (in the evolutionary sense) they developed vascular tissue, first at the base of the enation (as in *Asteroxylon*) and then throughout the enation, as in *Baragwanathia*, which thus became a true microphyll. According to the telome theory this series would be reversed: reduced vascularized microphylls would precede unvascularized outgrowths. Which

100 years ago

SOME forty years ago Dr. Joule raised the question whether a body that is magnetised undergoes any changes in its temperature; but the question has not yet received a definite solution, the rise of temperature which accompanies magnetisation being ascribed by some to induction currents, and not directly to magnetism. While recognising the influence of the former, Mr. Borgman has tried to show that there is also a change of temperature due to the magnetism and demagnetisation, and that the amount of heat thus disengaged is proportionate to the squares of the temporary magnetism. M. Bachmetieff, having made, at the University of Zurich, an extensive series of experiments, the first part of which is now published in the *Journal of the Russian Chemical Society* (vol. xvi. fasc. 3), arrives at the conclusion that magnetism, *by itself*, produces variations of temperature in magnetised bodies, and that this "magnetic heat" is equal to the product of the magnetic moment by the magnetising force multiplied by a constant; it increases also, within a certain limit, with the frequency of the interruptions of the magnetising current, and increases still more when the direction of the current is alternately changed. Its amount is not equal throughout the length of an iron cylinder, reaching its maximum about its middle and decreasing towards its ends. Its cause must be searched for in purely mechanical forces.

RATHER a strange occurence came recently before my notice, and thinking perhaps you might care to insert it in your columns, I send you the facts of the circumstance. A few days since, towards evening, I killed a snake just close behind my house; it measured about a yard and a half in length, was one of the most deadly of the numerous kinds of snakes found in Java, and bears the name of "Oelar belang." On examining it later I found what I thought to be the tail of another small snake protruding from its mouth, but on pulling it out I was greatly surprised to discover that it was really a snake of the same species, and of almost the same length. There was certainly not more than three inches' difference in the length of the two snakes, and at the time I killed the outside snake only about an inch and a half or two inches of the tail of the one he had swallowed protruded from his mouth. The natives here say that the two snakes must have been fighting, the victor afterwards swallowing his opponent. I should be pleased to know whether such an instance has ever before been brought before your notice, or whether it is really an uncommon case.
Soemedang, Java.

M. MONTGIGNY has recently published a pamphlet on the influence of the atmosphere in the apparition of colours seen in the scintillation of stars. He has previously noticed that there is a great predominance of blue in the scintillating colour when rain is approaching, and he is now so convinced of the accuracy of this forecast that it is included among others in the *Bulletin Météorologique* published by the Observatory of Brussels.

From *Nature* **30**, 3 July 1884.

theory is correct may seem simple to resolve by accurate age determination of plants whose anatomy is well known. But Stewart[10] proposed at least two lines of lycopsid evolution in the Lower Devonian, one evolving by the enation 'process' and the other according to the telome theory. Earlier, Schweitzer[12] suggested several lines. A great deal of controversy revolves around plants with 'microphylls'. In the Northern Hemisphere the earliest 'microphylls' are on the Gedinnian *Drepanophycus*[13] and 'microphylls' (with no trace of a vein) are known in *Asteroxylon*. Unfortunately many of the main morphological features of these plants, such as sporangia and spores, are unknown or poorly described. In the Southern Hemisphere much controversy surrounds *Baragwanathia* which occurs in Australia in rocks recently re-dated as Upper Silurian (Ludlow). If *Baragwanathia* is now correctly dated and is a true lycopsid then its presence in the Silurian may cast doubts on the origin of the lycopsids from the rhyniophytes.

With the expectation of continued discoveries by those who have already contributed to our knowledge of the early land floras and careful documentation of the geological age of their finds, the next few years promise to be as exciting as, but probably no less controversial than, the recent past. □

Immunology

The T-cell receptor completed

from Guil Winchester

T LYMPHOCYTES occupy a central position in the immune response. Like B lymphocytes they are capable of responding to an enormous variety of foreign antigens but they also control and coordinate the activity of other cells in the immune system. It was therefore a source of frustration and embarrassment to immunologists that the surface structure by which T cells recognize antigen remained obstinately invisible for many years. Over the past eighteen months, however, a number of consistent results have gradually been building up into a picture of the T-cell receptor. The publication of the complete sequence of the cDNAs for both subunits of a T-cell receptor on page 757 of this issue[1] completes the task.

The first glimpse of the receptor came last year when monoclonal antibodies, specific for individual T-cell clones, were found to precipitate protein dimers that seemed to be essential for the activation of T cells by antigens[2,3]. The polypeptide subunits of the dimers have slightly different molecular weights; each polypeptide contains constant regions, which are common to several clones, and variable regions which are clone-specific[4-6]. The protein chemists were then overtaken by the molecular biologists. In March of this year, two groups simultaneously published the sequence of cDNA clones from both mouse[7,8] and man[9] which now seem certain to code for the β-subunit of the receptor (Reinherz cited in ref.1). Since then, a genomic sequence for the β-subunit from mouse has been published[10]. The data show that, like the immunoglobulin gene, the β-subunit gene is split into segments in the germ line and the segments are brought together in differentiated cells to form a functional gene. Since each segment is present in a number of forms, which can be randomly assorted, the genes can encode an enormous number of receptors.

The α-subunit has, however, remained obscure. Now Susumu Tonegawa and his colleagues have isolated and sequenced two distinct cDNA clones from mouse, both of which are expressed and rearranged specifically in T cells[1]. Their sequence identifies one as the β-subunit and the other has all the properties predicted for the α-subunit.

The overall structure of the receptor presented by Saito *et al.* looks remarkably like two immunoglobulin light chains, both anchored in the membrane by a stretch of hydrophobic amino acids. Each chain has two domains on the external surface of the membrane, one constant and one variable, with the variable region at the amino-terminal end of the molecule. Between the constant domain and the cell membrane there is a short sequence which contains the cysteine that is thought to bind the two subunits together; this is followed by a sequence that spans the membrane and a short tail found in the cytoplasm. The α-subunit (which is the larger) has a slightly longer tail which contains an extra cysteine. Saito *et al.* suggest that this cysteine may form 'dynamic interactions' with other molecules. One candidate would be the T3 protein which is found in all mature human T cells and which seems to be involved in the triggering of T cells by antigen (for a review see ref.11). Removal of T3 from the surface (induced by anti-T3 antibodies) is accompanied by loss of the T-cell antigen receptor, implying that they are physically associated.

The new data provide Saito *et al.* with the first opportunity to compare receptor molecules from different T-cell subsets. The earlier clones encoding the β-subunit were isolated from T-helper cells, which activate the various effector cells in the immune system, while the cDNA clones described by Saito *et al.* come from cytotoxic T cells whose primary role is the direct killing of virally infected cells.

Although only the β-subunits from different subsets can be compared, the authors draw two tentative conclusions. One is that the variable-region genes used by cytotoxic and helper cells may well come from different gene pools; the two variable-region genes compared so far are only 20 per cent similar, which is comparable to the degree of similarity between the constant-region genes of the β-subunit of the T-cell receptor and those of the immunoglobulin light chains. Since helper-T cells usually recognize antigen in association with class II major histocompatibility complex (MHC) products, while cytotoxic cells recognize antigen in association with class I MHC products, dissimilarity between the variable regions of helper cells and cytotoxic cells is not unexpected. Moreover, it is compatible with the observation that helper cells and cytotoxic cells have different antigen repertoires.

More surprising is the fact that the β-subunit gene from cytotoxic cells shares a constant-region sequence with one of the helper-cell genes, the identity extending over the entire 3′-untranslated region. Differences between the constant regions of different T-cell subsets might have been expected; in an immunoglobulin molecule the constant region of the heavy chain determines its functional class. Two possibilities that might account for this anomaly are discussed by Saito *et al.* One is simply that functional differences between the two cell types lie on the constant region of the α-chain. The other is that the T-cell receptor is purely a recognition molecule and has a non-specific role in triggering effector functions. This question should be answered as soon as the α-subunit from a T-helper cell has been sequenced. At the rate events are moving in the field that should not be long delayed. □

Astronomy

Humps and superhumps

from Andrew King

CATACLYSMIC variables are close binary systems with orbital periods of a few hours, in which a white dwarf accretes matter from a faint low-mass companion star. They have shown themselves to be ideal systems for studying accretion processes, allowing frequent and stringent tests of theoretical ideas. An important new test is reported by Whitehurst, Bath and Charles on page 768 of this issue.

Cataclysmics show convincing evidence of possessing accretion discs; the accreting matter spirals slowly in to the white dwarf through a sequence of Kepler orbits (centrifugal force balancing gravity) under the action of dissipative forces, gradually giving up its gravitational potential energy to radiation. The stability of such a disc is a matter of great importance and under active debate, with dwarf novae providing the test ground. These are a class of cataclysmics which at irregular intervals (weeks to months) brighten dramatically (factors of about 10) in a day or less, remaining at this 'outburst' level for anything up to about 10 days (occasionally longer) before decaying back to their 'quiescent' level in 1 to 3 days. Two types of model have been proposed to explain this behaviour. In one, put forward by G.T. Bath and co-workers (University of Oxford), the 'donor' star (or secondary) is slightly unstable, and at intervals feeds bursts of mass transfer into the accretion disc. In the other, the outburst is a consequence of instabilities purely within the disc, without any change in the state of the secondary: work on these lines is being pursued by groups in Munich, Texas and Santa Cruz (see *Nature* **302**, 12; 1983). In their paper on page 768, Whitehurst *et al.* attempt to broaden the debate to include the phenomenon of 'superhumps'.

Superhumps are periodic increases in brightness (of up to 40 per cent) that are observed during the occasional 'superoutbursts', lasting about 12 days, that are additional to the 'normal' outbursts of one subclass of dwarf novae (the SU Ursae Majoris systems). Fascinatingly, the superhumps repeat on a period, P', that is a few per cent longer than the orbital period, and so cannot be due to some feature locked to the orbital rotation, such as an eclipse, for example. (It is an intriguing question whether the SU Ursae Majoris phenomenon is restricted to short-period dwarf novae, or whether observational selection effects prevent us recognizing it in longer-period systems. See Warner, B. in *Interacting Binaries*, eds Pringle, J.E.P. & Wade, R., Cambridge University Press; in the press, and van Paradijs, J. *Astr. Astrophys.* **125**, L16; 1983, for a discussion).

Whitehurst *et al.* focus on two systems which have orbital inclinations high enough that the secondary star periodically crosses our line of sight to the accretion disc, causing a deep eclipse, repeating at the orbital period, P. Painstaking efforts by B. Warner (Cape Town University) and W. Krzeminski (now Las Campanas) have yielded optical light curves through superoutbursts of these systems. The deep orbital eclipses are still there, indicating that most of the extra superoutburst light comes from the accretion disc. The interesting question which Whitehurst *et al.* address is whether the superhump light is eclipsed. Since the superhumps 'march' slowly through the orbital light curve on the beat period $(1/P - 1/P')^{-1}$ of about 2–3 days, there are phases when the orbital eclipse falls right on top of the superhump. If the superhump light were totally eclipsed at these phases, the residual light at the bottom of the eclipse should be exactly the same as that at phases where eclipse and superhump do not coincide. If, on the contrary, the superhump light were entirely uneclipsed, this residual light should vary in the same manner as the superhump itself. Using data from several eclipses, Whitehurst *et al.* conclude that the latter is the case. This virtually forces the site of the superhump phenomenon to be on the secondary star, as only a rather contrived model could restrict it to the small part of the accretion disc which is never eclipsed.

Activity on the secondary star is, of course, exactly what is invoked by the Bath model for dwarf nova outbursts; in the disc instability picture such activity would require a separate explanation. Moreover, most models place the superhump site on the accretion disc, where it would be partially eclipsed (see Warner, *op. cit.*). Whitehurst *et al.* suggest that the superhump is due to a bright spot on the secondary where part of the stellar envelope is lost to the white dwarf to cause the superoutburst: the spot is larger than usual since superoutbursts last longer than normal outbursts. The superhump period P' then represents the rotation period of the secondary; that is indeed expected to be just slightly longer than the orbital period P because of the synchronizing effect of tidal torques in a close binary.

All this presupposes that one accepts Whitehurst *et al.*'s conclusion that the superhumps are entirely uneclipsed. Because the superhump does not repeat precisely on each appearance, an escape hatch from this conclusion is still ajar, in that partially eclipsed superhumps may be allowable (see Whitehurst *et al.*'s Fig. 2). Whether they occur is a question that can be settled observationally, and should soon be, with the powerful stimulus of the new paper. But even when this question is disposed of, others will remain, such as why the superhump radiation pattern has such a highly structured and repeating nature. Superhumps and superoutbursts look set to challenge theoreticians and observers for some time to come. □

Molecular biology

Transposable elements and suppressor genes

from Ian J. Jackson

MOLECULAR biologists like mutations. Determination of the molecular basis of genetic mutations has already revealed unsuspected means by which gene expression can be disrupted. Now a class of mutant genes in species as diverse as yeast, *Drosophila* and mouse is providing more surprises as to mechanisms of mutagenesis, and may well yield information about the regulation of normal development. The mutations are caused by the insertion of transposable genetic elements in or near a gene and are suppressed by recessive genes which map elsewhere in the genome. Recently published work together with data discussed at a meeting in Colorado* reveals a remarkably unified theme among the mutations at the structural level, although the modes of action of the suppressor genes are proving to be somewhat enigmatic.

The transposable elements that cause the mutations include four classes: Ty of yeast, *copia* and *gypsy* of *Drosophila* and the ecotropic endogenous retroviruses of mouse. Each consists of a few kilobases of DNA flanked at either end by a duplicated sequence of several hundred base pairs, the long terminal repeat (LTR). In all cases where they cause a suppressible mutation, the transposable elements are inserted not into coding DNA but into an intervening or flanking sequence. After insertion, homologous recombination between the two LTRs can result in excision of the internal sequences, leaving a single LTR behind, and often resulting in total or partial reversion of the mutation. In all three species this occurs at a frequency of about 10^{-5}–10^{-6} per generation. Suppression of these

* UCLA Symposium, 'Genome rearrangement', held at Steamboat Springs, Colorado, 8–12 April 1984.

mutations, however, is not caused by an increase in the excision rate of the element. Instead, in some cases at least, it seems that the mutant phenotype is a result of transcription of the inserted element, and it is on this transcription that the suppressor genes act. All four classes of element have a promoter of transcription in one LTR and a terminator in the other, and thus will produce, under the right circumstances and where there has been no internal excision, a RNA molecule running the full length of the element. Whether, in all cases, this transcription causes the mutant phenotype remains to be seen, but the nature of the suppression and the wild-type function of the suppressor genes should prove revealing.

One good example of the phenomenon is the production of the auxotrophic mutations *his4-912* and *his4-917* in yeast by insertion of a Ty element upstream of the *HIS4* gene[1]. The *spt3-* mutation (formerly *spm3-*) of yeast suppresses *his4-917*, in which transcription of the Ty is away from the *HIS4* gene, but it does not suppress *his4-912*, in which transcription is towards *HIS4*. However, excision of most of Ty leaving behind a solo δ-sequence (the LTR of Ty) results in a cold-sensitive mutant phenotype which is then suppressible by *spt3-*. This arrangement has allowed Gerry Fink (Whitehead Institute/MIT) to examine the expression of the gene. At low temperatures, transcription of the *HIS4* gene initiates from the δ-sequence, 5′ of the gene, instead of the correct site. The resultant RNA is inactive. In the presence of *spt3-*, transcription starts from the correct position at all temperatures and all transcription from the normal origin in all δ-sequences of the cell is inhibited. Thus the simplest explanation for the mechanism of suppression is that transcription from the δ-sequences of the Ty elements placed in critical regions 5′ of a gene will prevent normal gene expression, and that *spt3-* mutants lack the ability to transcribe some or all of the Tys, so relieving the mutation. In this model the wild-type *SPT3* gene encodes a transcription factor required for initiation of transcription from δ-sequences. Perhaps the Ty mutations that are not suppressed by the *spt3-* mutation are transcribed by a different mode.

Inevitably, the genetics of the *Drosophila* suppressors is much more complex and the molecular biology less clearcut. The *suppressor of hairy wing* gene, *su(Hw)*, not only suppresses *hairy wing*, but a number of alleles at other loci, including *cut*, *scute*, *lozenge*, *forked*, *rudimentary* and several alleles of the homoeotic complex, *bithorax*. In work published last year, Modolell, Bender and Meselson reported the cloning of DNA from five suppressible alleles of *bithorax*[2]. Each of them contained the same transposable element, *gypsy*; indeed, all the genes affected by *su(Hw)*, except *rudimentary*, contained *gypsy* elements. Modolell *et al.* suggested that the product of the wild-type *su(Hw)* gene somehow interacts with *gypsy* to cause the mutations; a mutation at *su(Hw)* prevents this interaction and so suppresses the mutagenic effect of *gypsy*. At the Colorado meeting, Welcome Bender (Harvard University) presented data from *bithorax* which indicate that it may be transcription of the *gypsy* element which is causing the mutant phenotype. It cannot simply be the effect of insertion of *gypsy* into *bithorax* because other insertions at the same locations have a less pronounced effect. Similarly, chromosomal breaks have a different effect from *gypsy* insertion, suggesting that premature termination in the element is not to blame. Bender has gone on to show that in the presence of homozygous *su(Hw)*, transcription of the total population of *gypsy* elements is reduced fivefold. Whether the reduction of transcription is more from certain elements than from others is not known, but an effect on gene expression via transcription of the element is certainly strongly suggested. The problem remains of why *su(Hw)* suppresses two alleles of *rudimentary* which do not contain *gypsy* sequences.

The precise mode of action of the *su(Hw)* suppressor gene and the function of the product of its wild type have not emerged, but the observations of Paul Bingham (SUNY, Stonybrook) in relation to the *white-apricot* gene of *Drosophila* may be enlightening. The *white-apricot* (w^a) phenotype is caused by insertion of the transposable element, *copia*, into an intervening sequence of the *white* eye-colour gene (refs 3, 4 and K. O'Hare, personal communication). The effect of the w^a gene is suppressed by *suppressor of white-apricot*, *su*(w^a), which results in a darker eye colour, but can also be enhanced to produce a paler eye-colour by *suppressor of forked*, *su(f)*. Somewhat enigmatically, *su(f)* also suppresses the same alleles of *forked* and *lozenge* that are suppressed by *su(Hw)* and contain *gypsy* insertions. Bingham reported that a partial revertant of w^a, containing a single LTR insertion in place of the whole *copia*, was not affected by either *su*(w^a) or *su(f)*. This again suggests some effect of transcription of the element on the gene into which it has been inserted. This is further supported by evidence that the very low level of normal *white* transcript produced from the w^a gene was reduced still further in the presence of *su(f)*, but increased several fold when *su*(w^a) was present (Gerry Rubin, University of California, Berkeley).

To investigate the nature of suppression and the normal function of the suppressor genes further, Bingham has made several new mutations at *su*(w^a), almost all of which are recessive lethals. The exception, when homozygous, produces a fly that lacks wings and halteres, in a manner which suggests that specific cells of the imaginal discs die or fail to develop. The normal function of *su*(w^a), suggests Bingham, is to provide developmental signals within *Drosophila*. How the *copia* element in the w^a gene responds to these signals in such a way as to restore a normal white phenotype is a mystery. A guess would be that in certain cells the element is dependent for transcription upon these developmental signals, and that some mutations of the signal prevent the expression of this particular *copia*, and thus suppress w^a, whilst still allowing normal development of the organism.

Hope Sweet, of the Jackson Laboratories, reported last year the identification of the first recessive suppressor mutation in the mouse[5]. The gene, *dilute suppressor* (*dsu*), suppresses the *dilute* mutation (*d*) *Dilute* produces a pale coat colour. Jenkins *et al.* have shown it to be due to the insertion of an endogenous retrovirus into the mouse genome[6,7]. Revertants that are left with only one of the two LTRs have normal coat colour. Jenkins (University of Cincinnati) reported that the retrovirus seems to be inserted into a noncoding segment of DNA, so the means by which the retrovirus disrupts expression of the *dilute* gene are not evident. Perhaps the presence of the intact viral DNA prevents initiation, or causes premature termination or incorrect splicing of the *dilute* transcript. Although mice bearing the retrovirus do not become viraemic, the viral promoter might be active in melanocytes in a way that prevents correct *dilute* expression and, so, coat colour.

The effect of *dsu* on other genes may help explain how it suppresses *d* and, in turn, the cause of the *d* mutation. An allele of *d*, *dilute-lethal* (d^l), causes both a pale coat and a fatal neurological disorder. The coat coloration effect but not the lethality of d^l is suppressed by *dsu*. Hope Sweet (personal communication) has also shown that *dsu* suppresses *ashen*, a mutation which mimics the phenotype of *dilute*. Neither d^l nor *ashen* is associated with a retrovirus of the same type that causes *dilute*, although the presence of another virus or solo LTR has not been excluded. It seems, however, that the action of *dsu* is involved more directly in affecting the melanocyte morphology which gives rise to the dilute or ashen phenotype than in the expression of the genes themselves. How a recessive suppressor could act in this way, and the function of the wild-type *dsu*, are of considerable interest; experiments in progress at Cincinatti and the Jackson Laboratories should illuminate these points. □

A large-scale isotope anomaly in the Southern Hemisphere mantle

Stanley R. Hart

Center for Geoalchemy, Department of Earth, Atmospheric and Planetary Sciences, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

Basalts from many Southern Hemisphere regions have anomalous Sr and Pb isotopic characteristics. This article shows that the isotopic mantle anomaly is globe-encircling in extent, centred on latitude 30° S. Arguments suggesting that this mantle anomaly has been in existence for billions of years place severe constraints on mantle convection models.

RECENTLY, Dupré and Allègre[1] made an important observation concerning the existence of a large domain (10^8 km^2), centred in the Indian Ocean, which is delineated by oceanic island and oceanic crust basalts having anomalous Sr, Nd and Pb isotopic signatures. The existing isotopic data for young basalts show that this isotopic mantle domain, here termed the Dupal[1] anomaly, can be traced nearly continuously around the Southern Hemisphere between the Equator and 60° S. Part of this anomaly was previously delineated in the central Pacific[2]. This is the largest mantle geochemical domain yet delineated; I argue that this isotope domain was produced early in Earth history by core–mantle–crust differentiation processes. Survival of this anomaly strongly constrains models of mantle convection.

Isotope criteria

Three criteria are used to quantify the Dupal anomaly: (1) $^{207}Pb/^{204}Pb$ and (2) $^{208}Pb/^{204}Pb$ deviation from a Northern Hemisphere reference line (NHRL), (3) absolute value of $^{87}Sr/^{86}Sr$. Choice of a Northern Hemisphere Pb reference line is arbitrary, but convenient because of the abundance of data and essential colinearity of mid-oceanic ridge basalt (MORB) and oceanic island basalt (OIB) data on Pb–Pb plots. The reference lines were drawn to include MORB (both N-type and E-type), the islands of Hawaii, Iceland, Azores, Canaries and Cape Verde[3], and the north-east Pacific seamounts[4]. The equations of the adopted reference lines (NHRL) are:

$$^{207}Pb/^{204}Pb = 0.1084(^{206}Pb/^{204}Pb) + 13.491$$

$$^{208}Pb/^{204}Pb = 1.209(^{206}Pb/^{204}Pb) + 15.627$$

The magnitude of the isotopic anomaly of any given data set (DS) is then expressed as the vertical deviation in $^{207}Pb/^{204}Pb$ or $^{208}Pb/^{204}Pb$ from these reference lines:

$$\Delta 7/4 = [(^{207}Pb/^{204}Pb)_{DS} - (^{207}Pb/^{204}Pb)_{NHRL}]100$$

$$\Delta 8/4 = [(^{208}Pb/^{204}Pb)_{DS} - (^{208}Pb/^{204}Pb)_{NHRL}]100$$

For $^{87}Sr/^{86}Sr$, I use the absolute magnitude of the ratio, expressed as:

$$\Delta Sr = [(^{87}Sr/^{86}Sr)_{DS} - 0.7]10^4$$

The coherence between these three anomaly criteria is fairly good. Figure 1 shows the correlation between $\Delta 7/4$, $\Delta 8/4$ and ΔSr. The limiting precision of these criteria is that derived from the isotopic measurements themselves, and is largest for $\Delta 7/4$ because mass spectrometer fractionation effects are large relative to the total variation of $\Delta 7/4$ (measurement precision of ±2 units is 10% of total $\Delta 7/4$ variation of 20 units) and the fractionation vector is steeply inclined to the reference line. The $\Delta 8/4$ criterion is more robust because the fractionation vector is semi-parallel to the reference line and the total spread in $\Delta 8/4$ is large (measurement precision of ±5 units is only 3% of the total $\Delta 8/4$ variation of 190 units). Likewise, the measurement precision of ΔSr is small with respect to the observed spread. There are, of course, significant and unconstrained sources of uncertainty due to 'geological scatter'—the fact that averaged island data sets are used which may show large isotopic variations internally. For data sets involving many samples (Iceland, Hawaii, Galapagos), this scatter may be effectively averaged out; for some data sets, however, only one or two analyses are available and the problem of representativeness may be very serious. Note, however, that the variations of Pb isotopic ratios within a given island basalt suite are commonly sub-parallel to the reference lines, so that the calculated Δ values are insensitive to this kind of intra-island isotopic heterogeneity.

Data

The basic data set used is that compiled by Zindler *et al.*[3]; these data have been augmented with data from other studies, including some basalts from continental environments. The basic criterion has been to restrict the data sets to basaltic rocks and, for the continental environments, I have used only basalts for which Pb data exists, and which carry ultramafic mantle xenoliths (as a precaution against crustal contamination). These continental basalts are included because they seem to fit the picture, and fill in several important geographical gaps. Several of the basalt suites may be related to subduction zones (Pribilof's and Fiji); in the case of Fiji, only the young alkali basalt suite was used, as this is claimed to postdate subduction involvement[4]. Several suites range up to 85 Myr in age (Walvis Ridge, Rio Grande Rise, Ninety-East Ridge, New England seamounts); while the age correction will not significantly affect the anomaly criterion, it does affect the geographical position of these suites. (When formed, the Ninety-East Ridge samples were located some 40°–50° south of their present position.) Inclusion of these older suites shows that the Dupal anomaly has been a persistent feature of the mantle for at least 10^8 yr. Table 1 summarizes the data suites used, not including the Pacific ocean Sr data of Hedge[2] and Duncan and Compston[5].

World maps of these data, contoured for the three anomaly criteria, are shown in Fig. 2. While the configuration of the Dupal anomaly varies between the three different anomaly criteria, it is, nevertheless, a striking feature on all three maps, occupying a band of some 60° of latitude centred on 30°–40° S. The strongest maximum in the anomaly for all three criteria stretches from the southern mid-Atlantic Ridge to the central Indian ocean; a second maximum shows up on the ΔSr and $\Delta 8/4$ plots in the central Pacific. Very few Pb data have yet been published for this region. Based on available isotopic data (both Pb and Sr)[2,5–9], it appears that a configuration similar to the steep gradient between the islands of Tristan, Gough and St Helena in the Atlantic may exist, with Samoa, Raratonga and the Marquesas Islands reflecting a Dupal signature and the Tubuai Islands and southern Tuamoto Islands showing low anomaly values, similar to St Helena. Note that these two regions are almost antipodal to each other, with a near-equatorial two-fold axis of symmetry located at ~100° E.

Aside from the central Pacific, the other areas where there is little data coverage are the high latitudes; these regions are

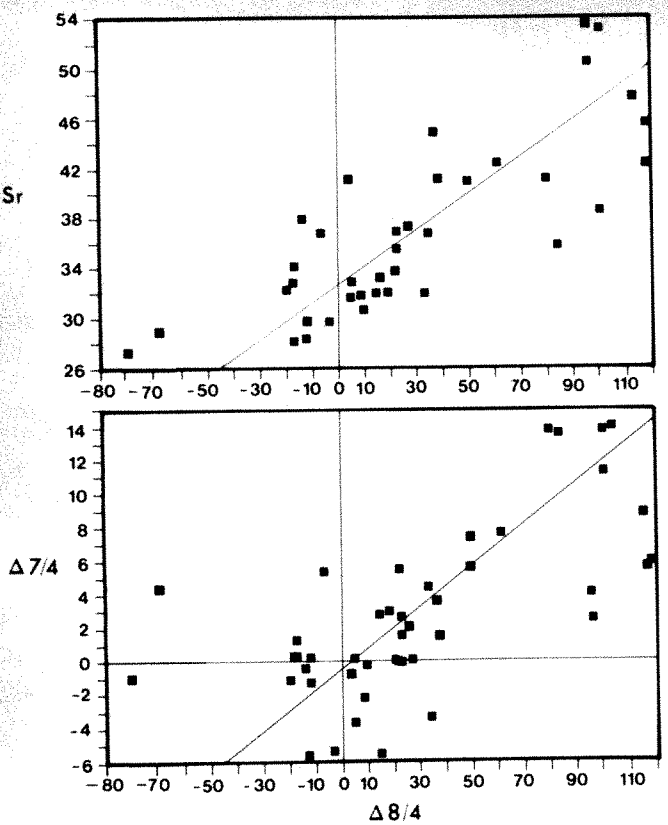

Fig. 1 Anomaly criteria ΔSr and Δ7/4 plotted against Δ8/4; data from Table 1. See text for definition of anomaly criteria. Best fit regression lines are: $\Delta Sr = 32.4 + 0.146(\Delta 8/4)$, $r = 0.85$; and $\Delta 7/4 = -0.86 + 0.127(\Delta 8/4)$, $r = 0.69$.

apparently characterized by unusually low ΔSr and negative values of Δ7/4 and Δ8/4. There is a good correlation between the features of the isotopic anomaly patterns of Fig. 2 and the degree-2 features of the Earth's geoid[10]. The geoid shows negative 'caps' in the polar regions and a nearly continuous belt of positive values centred on the Equator. The degree-2 geoid has been related by Busse[11] to a quadrupolar convection regime in the mantle, with lower mantle upwelling centred on an equatorial axis of symmetry. The isotopic anomaly data also suggest a simple quadrupolar pattern, but one which is more nearly axisymmetric with the Earth's spin axis. Higher-degree features of the isotopic anomaly pattern, such as the antipodal St Helena-type lows, have no obvious counterpart in the geoid.

Note that some complexities exist in the isotopic data for Hawaii and the Azores which have been obscured here by using averaged data. The Koolau series, Oahu[12] and the eastern end of Sao Miguel, Azores[6,13,14], show rather prominent Dupal signatures, with ΔSr = 41 and 53, and Δ8/4 = 51 and 44, respectively.

Implications

In evaluating models for the origin of this anomaly, several features need to be considered: (1) the fact that the anomaly is present in both OIB and MORB data (at least in the Indian Ocean); (2) the approximate coherence of the three anomaly criteria; and (3) positive values of the anomaly criteria require high time-integrated values for the parent/daughter ratios in the source (in the case of Δ7/4, the required high U/Pb value must, in addition, date back to early in Earth history), and (4) evidence for the Dupal signature in the past geological record. These points will be considered individually.

(1) Dupré and Allègre[1] proposed that the MORB reservoir (upper mantle) is polluted by material from the OIB reservoir (lower mantle), thereby transferring the anomaly signature from the lower to the upper mantle without creating complete isotopic identity between the two reservoirs. One can also conceive of a non-layered mantle scenario, where the OIB reservoirs are blobs distributed through the MORB reservoir and where partial cross-pollution takes place during partial melting and subsequent high-level magmatic processes[3,15].

Another explanation would relate these two reservoirs through a common parentage. If the depleted MORB reservoir is created by extraction of continental crust[16–19], and if the Dupal anomaly signature predates the formation of the MORB reservoir, then the existence of the anomaly signature in the MORB reservoir could simply be inherited from its mantle precursor. To be viable, this mechanism would require that the various MORB and OIB reservoirs have maintained their relative lateral positions over long periods of geological time, which seems unlikely in view of the rapid convective motions of the upper MORB reservoir. I prefer the 'pollution' explanation advanced by Dupré and Allègre[1].

(2) As shown in Fig. 1, the three anomaly criteria are reasonably, though not perfectly, coherent (r ranges from 0.69 to 0.85). Each anomaly criterion depends essentially on the time-integrated parent/daughter ratio in the reservoir; their coherence therefore suggests that the Dupal reservoir has higher time-integrated values of Rb/Sr (ΔSr), Th/Pb (Δ8/4) and $^{235}U/Pb$ (Δ7/4) than the reference reservoir. Because of the coupling of U/Pb and Th/Pb in the $^{208}Pb/^{204}Pb$–$^{206}Pb/^{204}Pb$ plot, the high Δ8/4 also requires high Th/U ratios. In other words, the Dupal source is characterized by high relative Rb/Sr, $^{235}U/Pb$ and Th/U; in most petrogenetic processes, the numerator element in these ratios is observed to behave more incompatibly than the denominator element, so that the approximate coherence of the three anomaly criteria is not surprising.

(3) The Dupal reservoir is characterized by relatively high time-integrated values of Rb/Sr, $^{235}U/Pb$ and Th/U. What does this imply for development of the Dupal reservoir? One obvious source for high Rb/Sr, U/Pb and Th/U material is the continental crust, and in fact, Dupré and Allègre[1] favoured the subduction of sediments into the mantle to explain the anomalous isotopic characteristics of the Indian ocean Dupal island suite. Other authors[3,20–22] have argued for reinjection of oceanic crust or sediment to provide a component in many or all OIBs.

Recent (<500 Myr) injection of crustal material is not a satisfactory mechanism for production of the Dupal isotopic signature, as this would produce high angle Pb isotope arrays, with an apparent origin somewhere along the Northern Hemisphere reference array. With the exception of Tristan, intra-suite Dupal trends appear instead to be subparallel to the reference array (for example, Gough, Walvis, Bouvet, Kerguelen). Furthermore, the suites showing the most marked Dupal signature define an inter-suite Pb–Pb array which is parallel to the reference array, but shifted to higher $^{207}Pb/^{204}Pb$ and $^{208}Pb/^{204}Pb$ values. This array, which is defined by 90° E-ridge—Discovery Seamount, Gough, St Paul, Crozet and Amsterdam—covers a large range in $^{206}Pb/^{204}Pb$ (17.9–19.2), and cannot be generated by contamination of reservoirs lying along the reference array with crustal material, even if that were heterogeneous. Inclusion of Sr isotope data only enhances the implausibility of this mechanism, as $^{87}Sr/^{86}Sr$ shows no significant correlation with position along this 'upper bound' array.

This problem can be circumvented if the crustal contaminant was reinjected into the mantle a long time ago, before the processes which have subsequently produced the 'lineation' of the reference suite along an apparent 1,700-Myr isochron, and which are also responsible for the subparallel lineation of the Dupal suites. Several reinjection models[3,21,22], in fact, propose that ancient oceanic lithosphere is responsible for the isotopic signature of many OIB suites, though it has yet to be demonstrated that such material will have the requisite high U/Pb and Th/U ratios. Furthermore, enhanced U/Pb ratios in altered oceanic crust should be accompanied by enhanced $U/^{3}He$ ratios, which would lead in several billion years to markedly enhanced $^{4}He/^{3}He$ ratios; there is no obvious difference in He isotope ratios between Dupal and non-Dupal islands[23].

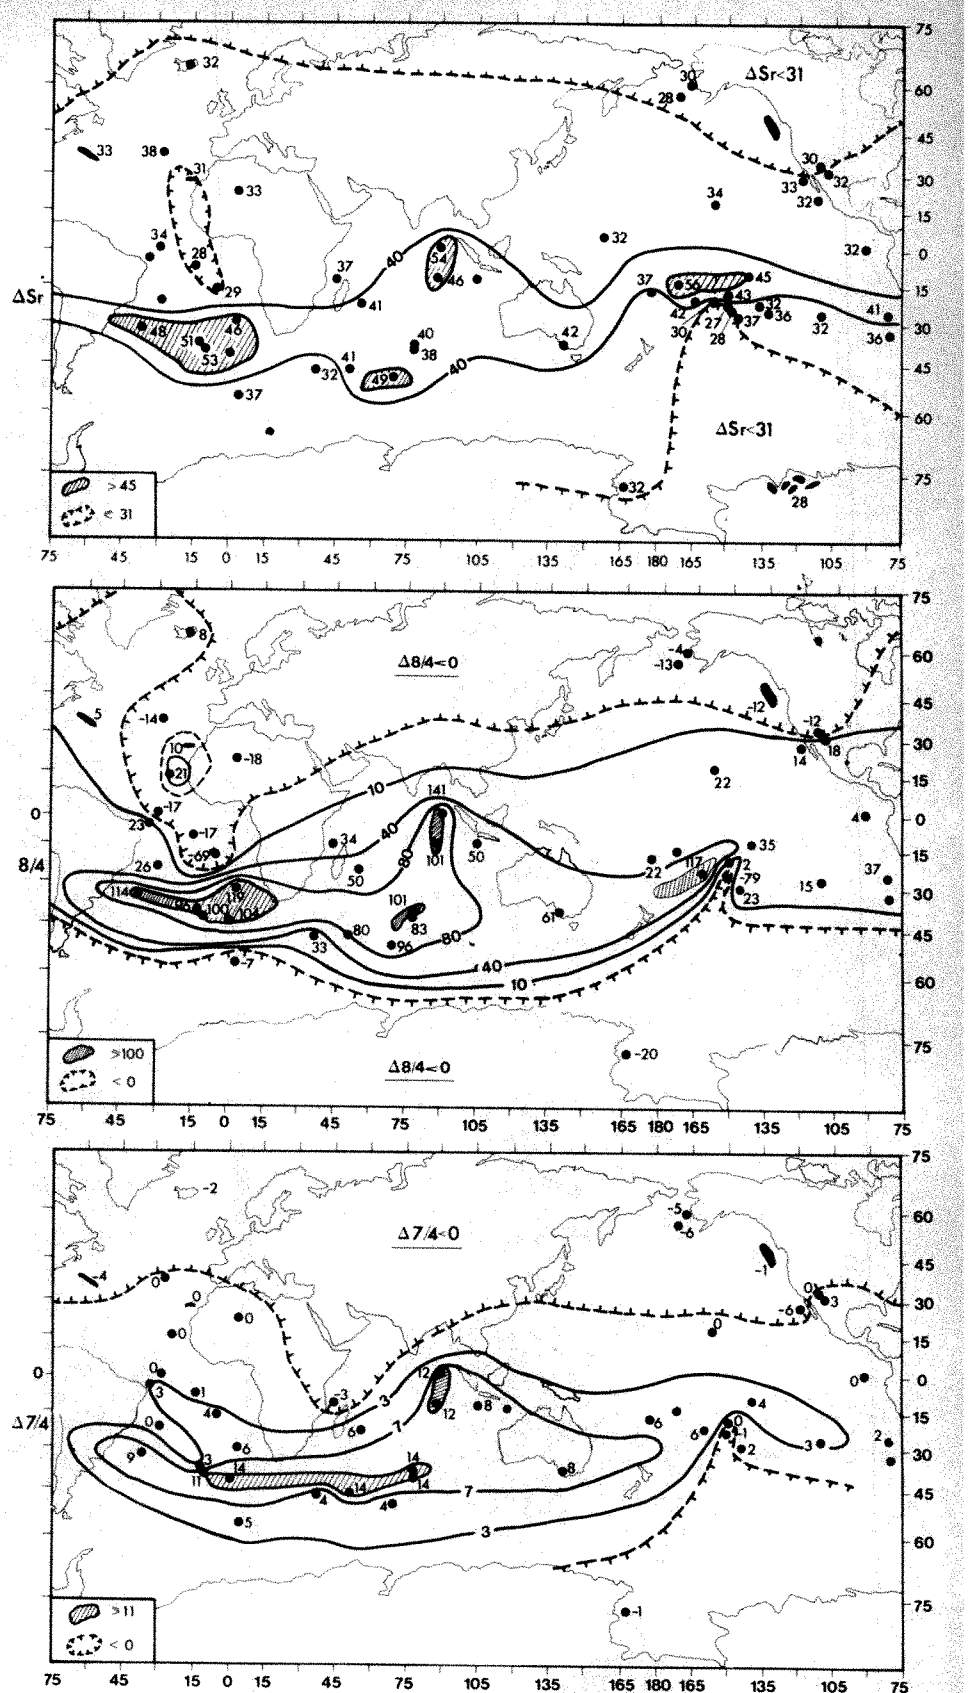

Fig. 2 World maps (Miller cylindrical projection) showing distribution of the ΔSr (upper), Δ8/4 (middle) and Δ7/4 (lower) anomaly criteria; contours are fitted by eye and are subjective in many areas of non-existent data. Anomaly data are from Table 1, augmented, in the case of ΔSr, by data from the Pacific Ocean[2,5] and Antarctica[46]. Also shown on all three maps are data for the Ninety-East Ridge[1], although these are samples of older age and should be plotted at a more southerly position consistent with their location of origin.

It has also been suggested that ancient sub-continental lithosphere may delaminate and provide the necessary 'enriched' reservoir[24]. This mixing would have to have occurred early in Earth history for the reasons discussed above. In any event, these reinjection models will need to address the fact that the Dupal anomaly is a coherent geographical domain, and is not randomly dispersed amongst the various OIB locations.

I present the following alternative hypothesis to the reinjection model of the Dupal anomaly, as a stimulus for further investigation. First, the anomaly is related to very early (>3,000 Myr) development of U/Pb, Rb/Sr and Th/U enrichments in the Dupal source mantle relative to the reference mantle. Second, this relative enrichment either derives directly from constructional heterogeneties in the initial Earth, or is related to heterogeneties developed during early stages of continental crust extraction. (More crust was extracted from the reference mantle reservoir, causing it to be more depleted than the Dupal mantle reservoir.) Third, in common with most other oceanic Pb models,

Also utilized are Sr isotope data on Gough, St Paul, Kerguelen, Amsterdam (S.R.H. and C. Brooks, unpublished data), and Kerguelen, Easter, Guadalupe, Gough, Tristan and St Helena[6]. Numbers in parentheses after locality are the least numbers of analyses involved in cases for which $n < 4$. Pb data from ref. 9 has been normalized to absolute values using California Institute of Technology Pb standard data of ref. 45.

* Unpublished data from S.R.H. and † J. Morris, ‡ A. J. Erlank, § H. Staudigel, ‖ D. Gerlach.

some means is required to produce the apparent secondary isochron Pb–Pb arrays observed in intra-island basalt suites, and in the reference reservoir suites as a whole. This requires a process, with a mean age of ~2,000 Myr, that will increase the U + Th/Pb ratio of all oceanic mantle sources. Core-pumping of Pb has been advocated for this[16], as has concentration of Pb into the lower crust[19]. Mixing with ancient high U/Pb oceanic crust (with present $^{206}Pb/^{204}Pb \geq$ that of St Helena) has also been advocated[3]. I have little to add to the problem of the Pb paradox, other than my prejudice that the Dupal anomaly predates, and is perhaps not even related to, the events which have created the oceanic Pb paradox.

(4) As outlined, the Dupal anomaly is globe-encircling and restricted to the Southern Hemisphere. I have argued above that this anomaly has probably existed as a mantle entity for billions of years.

Support for the antiquity of this anomaly comes from Sinha[25] who compiled existing Pb isotope data for continental rock and ore leads of all ages, and showed that samples from the Southern Hemisphere fall along a higher μ growth curve than did those from the Northern Hemisphere (closed system μs of 9.3 and 8.9 respectively). This distinction was present even in the oldest rocks considered (>3,000 Myr). This hemispheric distinction is not apparent in Pb data from conformable ore deposits[26,27] but many of these leads appear to be generated in an arc setting and may involve rather extensive mixing in sedimentary environments. Sinha did not compile $^{208}Pb/^{204}Pb$ data, so the existence of a Δ8/4 anomaly in this continental data set is not verifiable at present.

Note that the rock Pb isotopic data sets compiled by Manhes *et al.*[28], also show the Sinha divergence. The eight Southern Hemisphere data sets have a higher average $^{207}Pb/^{204}Pb$ intercept value than do the 12 Northern Hemisphere data sets. These sets consist of data of variable analytical quality, and represent a diversity of rock types with both crustal and mantle affinities. If the Sinha hemispheric Pb divergence withstands further scrutiny, two important conclusions are implied: (1) if this divergence is genetically related to the Dupal anomaly, then the Dupal anomaly is indeed of ancient constitution and; (2) the existence of a Dupal-type anomaly in continental rocks suggests a genetic link between oceanic island mantle and continental crust. Because the continental crust is presumed to derived from the mantle, it could carry the Dupal signature with it; on the other hand, if the Dupal anomaly originated by the ancient reinjection of continental material, the signature may have been originally bred in the Gondwana crustal entity and have been inoculated into the subjacent mantle during later crustal reinjection.

Future directions

The Dupal anomaly is defined on the basis of the present position of the oceanic islands and continents. If the anomaly is of ancient parentage where were these continental blocks and oceanic reservoirs in the past? Have they been anchored to the Southern Hemisphere? Could there be a mantle convection regime which would not, in billions of years, destroy the isotopic signature of the Dupal mantle, and which would not decouple the geographical positions of the Dupal continents and mantle reservoirs?

The next step is to define the Dupal anomaly more clearly by analysis of basaltic rocks from both oceanic and continental regimes in the Southern Hemisphere. It will also be useful to search for Dupal signatures in Southern Hemisphere volcanic arcs.

Complete primary structure of a heterodimeric T-cell receptor deduced from cDNA sequences

Haruo Saito, David M. Kranz, Yohtaroh Takagaki, Adrian C. Hayday, Herman N. Eisen & Susumu Tonegawa

Center for Cancer Research and Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

Two related, but distinct, cDNA clones have been isolated and sequenced from a functional murine cytotoxic T-lymphocyte clone. The genes corresponding to these cDNA are expressed and rearranged specifically in T cells and both have similarities to immunoglobulin variable and constant region genes. It is concluded that these genes code for the two subunits of the heterodimeric antigen receptor on the surface of the T cell; its complete deduced primary structure is presented.

THE most characteristic feature of the vertebrate immune system is its capacity to respond to an enormously diverse set of antigenic determinants. At the molecular level this capacity has been traced to an equally diverse set of glycoproteins that are synthesized in B and T lymphocytes. The glycoproteins produced by B cells, called antibodies or immunoglobulins, recognize and bind free antigens and are responsible for humoral immunity, while the T-cell molecules, commonly called T-cell receptors, recognize cell-bound antigens in the specific molecular context of self major histocompatibility complex (MHC) products[1–3] and are responsible for cellular immunity. The MHC-restriction is an acquired phenomenon[4,5] determined not by the genotype of the T cells but by that of the host thymus in which the T cells differentiate.

During the past several years extensive studies on the biology and chemistry of immunoglobulin molecules and their genes have illuminated structural and functional properties of these physiologically critical molecules and the genetic origins of their enormous diversity[6]. However, in spite of the equally central position they occupy in immunological phenomena, the chemical nature of the T-cell receptors has been elusive[7]. Only recently has the first glimpse of these molecules been obtained through the development of effective antisera and monoclonal antibodies that recognize and precipitate clone-specific proteins on the surface of functional T-cell clones, hybridomas or T-cell tumours[8–10]. These studies suggested that the portion of the receptor determining specificity is a heterodimeric glycoprotein corresponding to a molecular weight (M_r) of about 90,000 (90K) consisting of a 40–45K α-subunit and a 42–44K β-subunit. Moreover, peptide fingerprint analysis suggests that both the α- and β-subunits, like immunoglobulin heavy and light chains, are composed of variable (V) and constant (C) regions[11–13]. These studies, however, have not provided a primary structure because of the difficulty in preparing a sufficient amount of purified receptor protein.

More recently two groups of workers, using an entirely different approach, succeeded in isolating T-cell-specific cDNA clones of mouse or human origin which show significant

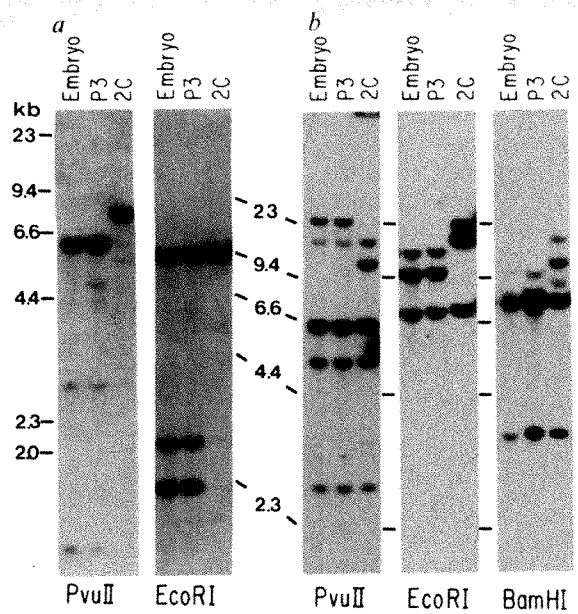

Fig. 1 Southern blot analysis of DNA from BALB/c embryos, myeloma P3 (BALB/c derived), and CTL 2C (BALB.B). DNA was digested with the indicated restriction enzymes, electrophoresed through 0.8% agarose, blotted onto nitrocellulose, and hybridized with ^{32}P-labelled, nick-translated inserts from clone pHDS11 (*a*) or clone pHDS4 (*b*). Hybridization was carried out at 42 °C in 50% formamide and 4×SSC. The filters were washed at 65 °C in 0.25% SSC. Separate experiments showed that BALB/c and BALB.B embryo patterns are indistinguishable.

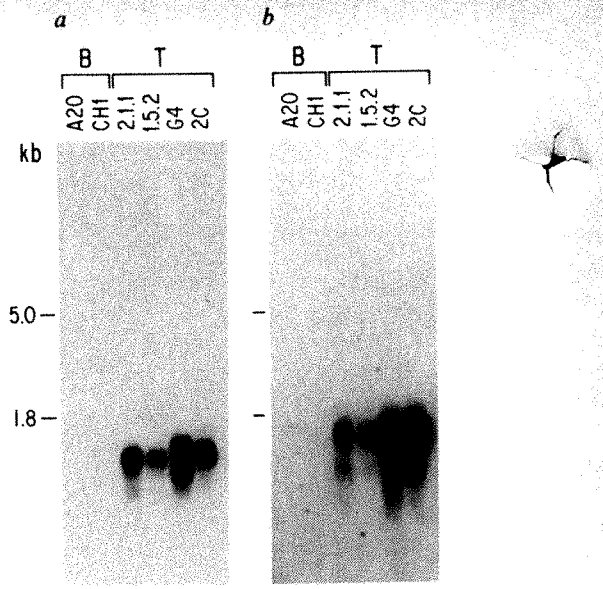

Fig. 2 RNA blot analysis of poly(A)$^+$ RNA from various B- and T-cell lines. RNA was extracted from B-cell lymphomas A20-2J and CH1 and alloreactive (H-2^b anti-H-2^d), cytotoxic T-lymphocyte clones 2.1.1, 1.5.2, G4 and 2C. Approximately 1.5 μg of poly(A)$^+$ RNA were denatured with glyoxal and electrophoresed through 1% agarose in 10 mM sodium phosphate buffer, *p*H 6.5. RNA was transferred to nitrocellulose and hybridized to ^{32}P-labelled, nick-translated inserts from clone pHDS11 (*a*) or clone pHDS4 (*b*). Positions of rRNA markers (5.0 and 1.8 kb) are as indicated.

homology to immunoglobulin genes[14–16]. Consistent with their interpretation that these cDNA clones represent one of the two subunits of the receptor, one group has shown that the cDNA encodes a protein composed of an amino-terminal V and a carboxy-terminal C region[16]. They also showed that the corresponding genomic DNA sequences have undergone clone-specific somatic rearrangements in various T-cell lines[15,16]. As the predicted amino acid sequences encoded by the mouse and human cDNA clones isolated by Hedrick *et al.*[16] and Yanagi *et al.*[14], respectively, are highly similar in the C regions, it is very likely that they represent only one of the two subunits of the T-cell receptor.

We have applied the subtraction-cloning method of Davis and his co-workers[15] to a clone of murine alloreactive, cytotoxic T lymphocytes (CTL) and have identified two clearly distinct, mutually non-cross-hybridizing T-cell-specific cDNA clones. Both of these clones show significant sequence homology to immunoglobulin light and heavy chains as well as to the putative receptor genes of Hedrick *et al.*[16] and Yanagi *et al.*[14]. In fact, one of our cDNA clones and those of Hedrick *et al.* have a virtually identical nucleotide sequence in the entire constant and 3′ untranslated regions. In addition, the genes corresponding to both types of our cDNA have undergone rearrangements in this as well as other cytotoxic T-cell clones.

On the basis of these findings we believe that we have identified and sequenced the genes coding for both subunits of the heterodimeric T-cell receptor of a functional CTL clone. We report here the predicted complete primary structure of this T-cell receptor.

Isolation of T-cell-specific cDNA clones

The alloreactive CTL clone 2C, of BALB.B origin and specific for products of the *D* end of the BALB/c *H-2* complex (*d* haplotype), has been described previously[17]. The cDNA synthesized on the poly(A)$^+$ RNA from 2C was subtracted twice with poly(A)$^+$ RNA from a mouse B-cell lymphoma, A20-2J (ref. 18), according to Hedrick *et al.*[15] and a library was constructed from the subtracted cDNA using the vector pBR322 and a standard G·C tailing method. A quarter of this library, containing about 20,000 independent cDNA clones, was subjected to differential screening using two hybridization probes. The first was the 2C cDNA prepared from the poly(A)$^+$ RNA of membrane-bound polysomes by subtraction with poly(A)$^+$ RNA from another B-cell lymphoma, CH-1 (ref. 19). The second was the cDNA prepared from the total poly(A)$^+$ RNA from A20-2J. One hundred and forty 2C-specific cDNA clones were identified and their plasmid DNA was used as hybridization probes in a series of RNA blotting experiments in order to confirm the T-cell-specific expression of the corresponding genes. This permitted us to group the T-cell-specific cDNA clones into at least 10 sets according to the sizes of the corresponding mRNA present in 2C. One was judged to be for the T-cell-specific surface marker Thy-1 on the basis of its hybridization to a previously identified Thy-1 cDNA clone (a gift of Mark Davis).

Two distinct cDNA classes

As was the case in the work of Hedrick *et al.*[15,16], one of our assumptions was that the receptor genes in question are rearranged in CTL. Thus we used representative cDNA clones of each set as hybridization probes and compared *Eco*RI-digested genomic DNA from 2C and BALB.B embryos by Southern blot analysis (data not shown). This screening led to the identification of two distinct classes of cDNA, one represented by clone pHDS11 and the other by clones pHDS4 and pHDS203, the genes of which are rearranged in 2C. The other classes of cDNA did not give any indication of DNA rearrangement.

Figure 1*a*, *b* shows the results of more extensive Southern blot analysis carried out using clone pHDS11 and pHDS4 as hybridization probes, respectively. The results can be summarized as follows. First, the hybridization patterns obtained by the

two probes are clearly distinct, confirming that the two classes of cDNA clones represent two different sets of genes that do not cross-hybridize to a detectable level in the conditions used. Second, with either probe the hybridization patterns obtained with 2C DNA are different from the patterns obtained with BALB embryo DNA. Third, the myeloma P3 DNA patterns are the same as the embryo DNA patterns. In addition, DNA from five different CTL clones was analysed and each gave patterns different from those of embryo DNA with at least one enzyme (data not shown). Considering the multiplicity and specificity of the pattern differences, these results strongly suggest that genes corresponding to both cDNAs have undergone gross sequence rearrangement in 2C.

The T-cell-specific expression of these genes has been confirmed by analysing poly(A)$^+$ RNA from 2C and three other independently derived alloreactive CTL as well as two B-cell lymphomas, A20-2J and CH1. As shown in Fig. 2*a*, *b*, each of the two cDNA probes detected RNA of distinct sizes in all four CTL but not in either of the B-cell lymphomas, although the relative content, and in some cases the size, of the RNA varied somewhat between CTL. When analysed with the clone pHDS11 probe, CTL 2C, 1.5.2 and 2.1.1 all gave a major RNA component of about 1.3 kilobases (kb) while CTL G4 contained two major components of 1.4 and 1.2 kb. On the other hand, all four CTL gave a 1.5 kb RNA component with the clone pHDS4 probe.

Nucleotide sequence analysis

The restriction maps of the three cDNA clones, pHDS11, pHDS4 and pHDS203, were constructed by standard procedures (Fig. 3), and the DNA sequences were determined by the method of Maxam and Gilbert[20] according to the strategy shown in Fig. 3. As both the restriction maps and DNA sequences (see below) confirm that pHDS4 and pHDS203 are derived from the same gene while pHDS11 represents a distinct one, we will describe the sequence features of the two genes separately.

The entire nucleotide sequence of the 1,054 base pair (bp) insert of clone pHDS11 is shown in Fig. 4*a*. The longest open reading frame is composed of 879 nucleotides whose corresponding amino acid sequence of 293 residues is also shown in Fig. 4*a*. For reasons given below, the codons are numbered starting with the triplet GAC at nucleotide positions 36–38. Between codons 110 (Glu) and 236 (Cys) the pHDS11 sequence is identical to the sequence of the corresponding region of Hedrick *et al.*'s thymocyte cDNA clone, 86T1 (ref. 16), except for one base pair difference in codon 159 (Arg). According to these authors this region defines the major body of the C region: codons 109 (Leu) and 110 (Glu) define the joining (J) and C region boundary while codon 236 (Cys) precedes the N-terminus of the transmembrane segment. The sequence identity is even more striking between pHDS11 and 2B4.71, the latter being a cDNA clone isolated from a T-helper cell hybridoma specific for pigeon cytochrome *c* (ref. 21). From codon 109 (Leu) the two sequences are virtually identical throughout the C regions and the entire 3′ untranslated regions. The exceptions are two base pair differences, one in codon 159 (Arg) and the other at nucleotide position 992.

Between codons 97 and 109 the pHDS11 sequence is similar to but distinct from the corresponding sequence of 86T1 or 2B4.71. As pointed out by Hedrick *et al.*[16], this region is strikingly homologous to the *J* segments of immunoglobulin genes. In fact the pHDS11 *J* sequence corresponds exactly to the sequence of the J_T7 genomic segment recently identified and characterized by Chien *et al.*[21].

Between codons 1 and 97 the pHDS11 sequence is quite different from the sequence of the corresponding region of either 86T1 or 2B4.71 (Fig. 5*a*). However, patches of conserved residues clearly exist throughout the three sequences and also between these sequences and those encoding immunoglobulin V regions of both light and heavy chains (the latter not shown). Particularly noteworthy conservations are the two Cys residues that are involved in intra-domain disulphide linkages in immunoglobulin V regions (residues 23 and 91 in Figs 4*a* and 5*a*). The Trp residue that is universally conserved in immunoglobulin V regions is also present in the corresponding position of the T-cell proteins (residue 34).

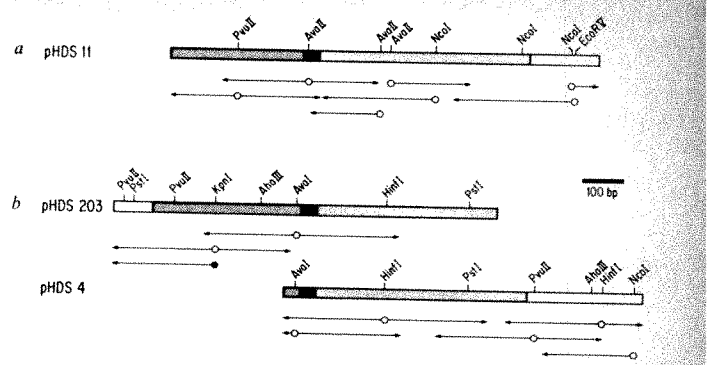

Fig. 3 Restriction maps of the inserts of cDNA clones isolated from CTL 2C. The maps were constructed by the standard single, double or triple digestions of the plasmid DNA. The *V*, *J*, *C* and 5′- or 3′-untranslated regions are shown by ▩, ■, ▨ and □, respectively. Also shown are the sequencing strategies used to produce the nucleotide sequences shown in Fig. 4. The 5′- and 3′-end labellings are indicated by ○ and ●, respectively.

At the 5′ end of the open reading frame (see Fig. 4*a*) there is a stretch of 11 highly hydrophobic residues that probably comprise part of a signal peptide[22]. The position of the N-terminal residue of the mature protein is ambiguous. However, homology between the pHDS11 protein and immunoglobulin V regions, particularly V_κ regions[23], suggests that Asp at position 1 is the N-terminal residue.

As already pointed out by Hedrick *et al.*[16], another stretch of a highly hydrophobic region of about 22 residues, evidently constituting a transmembrane peptide, occurs immediately before the C-terminal 5 hydrophilic residues; the latter are thought to extend into the cytoplasm. Overall, the gene defined by pHDS11 can encode a processed protein of 282 residues with a molecular weight of 32K.

The composite nucleotide sequence of 1,286 bp defined by the two overlapping cDNA clones pHDS4 and pHDS203 is shown in Fig. 4*b*. The longest open reading frame begins with the Met codon at nucleotide positions 88–90, extends over a stretch of 912 bp, and ends at nucleotide position 999. The predicted amino acid sequence is also shown in Fig. 4*b*. This sequence is significantly homologous to those of pHDS11, 86T1, 93G7 immunoglobulin heavy chain, MOPC603 immunoglobulin κ light chain, and MOPC104E immunoglobulin λ1 light chain. This is shown in Figs 5*b* and 6 where the pHDS4/203 protein sequence is compared with the V (or V+D), J and C region sequences of the other five proteins. Homology is evident in all three regions. The relatedness of the pHDS4/203 protein to the other five proteins in each of the three regions ranges over 18–23% for the V or V+D region, 21–50% for the J region and 16–22% for the C region. The similarity occurs in patches and in the case of the V (or V+D) region these patches tend to correspond to the framework regions (FR) of immunoglobulin V regions. In addition, many of the residues shared by the five non-pHDS4/203 proteins are also shared by the pHDS4/203 protein. These residues (indicated in Fig. 5*b* by *) include the Cys residues involved in the intra-domain disulphide linkages as well as the Trp residue which is universally present at the boundary of the first hypervariable (HV-I) and FR-2 segments of all immunoglobulin V regions studied to date[23].

As in the pHDS11 protein, the peptide at the amino-terminal end of the pHDS4/203 protein is highly hydrophobic and most probably constitutes a signal peptide. Accordingly the N-terminal residue of the processed protein cannot be unambiguously determined from the cDNA sequence. However, we believe that the N-terminal residue is the Gln at position 1 in Figs 4*b* and 5*b*. This is because the N-terminal residue of the α-subunit of the T-cell receptor is blocked, probably by a pyrollidone carboxylic acid residue (S. Schlossman, personal

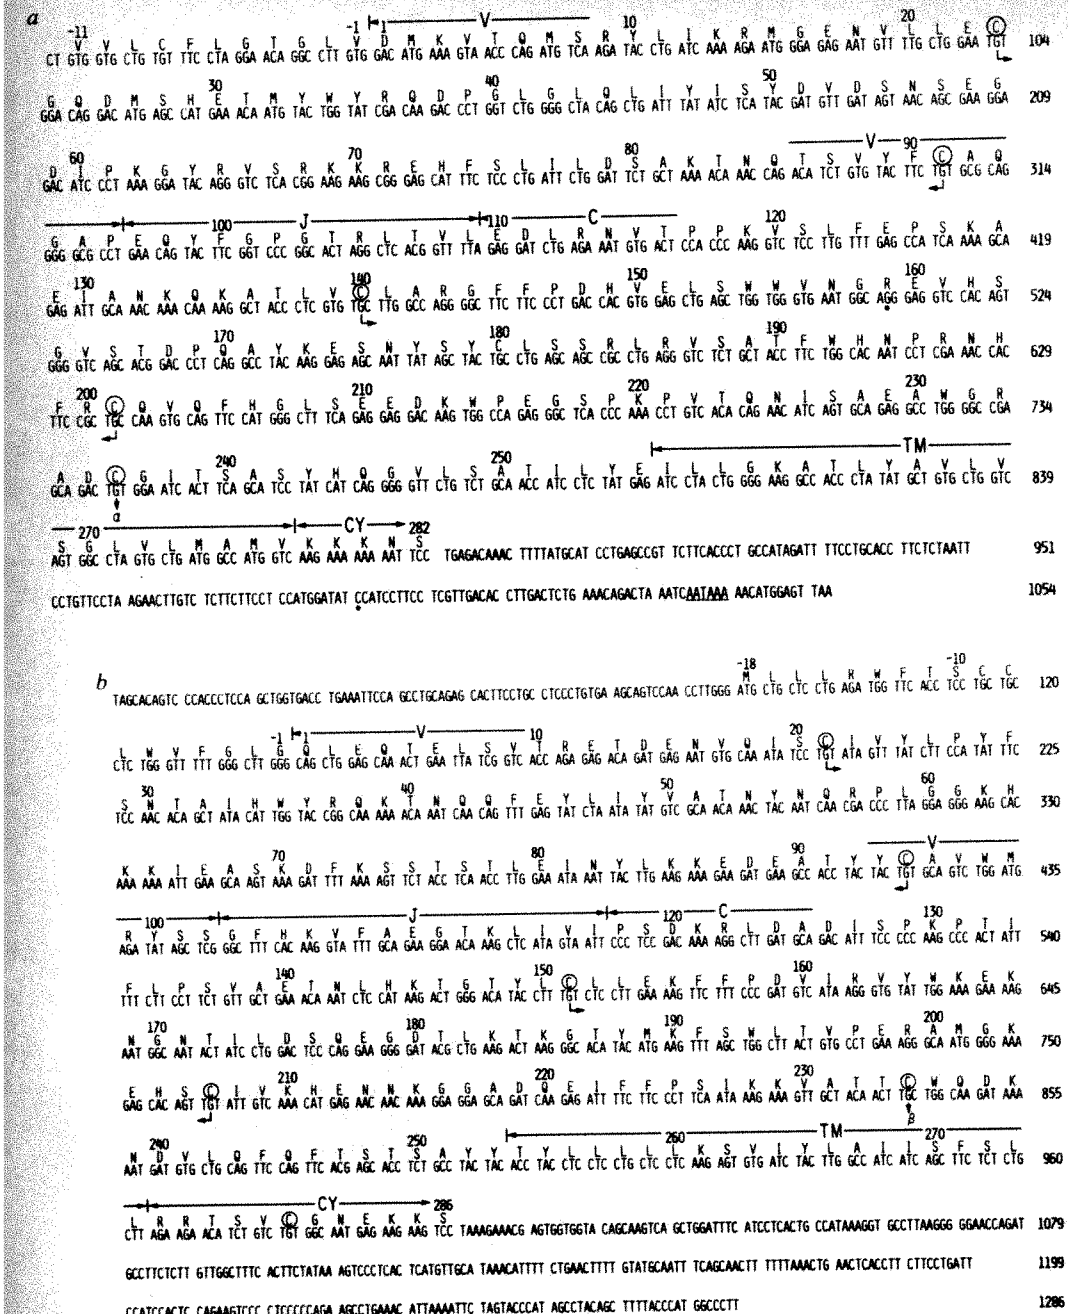

Fig. 4 The determined nucleotide and predicted amino acid sequences of cDNA clones pHDS11 (*a*) and pHDS4/pHDS203 (*b*). The numbers given above the amino acid sequences designate the residue positions. The numbers on the right show nucleotide positions. The negative numbers are for predicted signal peptides. The V, J, C, TM (transmembrane) and CY (cytoplasmic) regions are indicated although the exact boundaries are somewhat ambiguous. The cysteines thought to be involved in intra-domain or inter-chain disulphide linkages are indicated. The two nucleotides that are different in the C or 3′-untranslated regions of pHDS11 and 2B4·71 (ref. 21) are indicated by *. The oligonucleotide thought to be a signal for the poly(A) attachment site is underlined in *a*.

communication). In addition, this residue number assignment places the first conserved Cys residue at position 21, which is similar to the position (22 or 23) of the corresponding Cys residues in immunoglobulin regions[23].

Near its carboxy-terminus the pHDS3/203 protein also contains the second highly hydrophobic peptide of about 20 residues reminiscent of a transmembrane peptide. This region is followed by a hydrophilic C-terminal segment of 12 residues which probably comprises an intracytoplasmic peptide. The processed protein is 286 residues long and the calculated molecular weight is 33K.

The α- and β-chain

On the basis of T-cell-specific expression, T-cell-specific rearrangement and sequence similarity to immunoglobulin chains, the cDNA clones reported by Hedrick *et al.*[16], Yanagi *et al.*[14] and Chien *et al.*[20] have been thought to code for one subunit of the murine and human T-cell receptor. That this subunit is the β-chain has recently been shown by E. L. Reinherz and his co-workers (personal communication). They have purified the β-subunit of the receptor from a human T-cell tumour REX and determined the amino acid sequence of the N-terminal region. This sequence matches well with the N-terminal amino acid sequence predicted from the nucleotide sequence of the human cDNA clone of Yanagi *et al.*[14]. We have shown that pHDS11 gene is expressed and rearranged in CTL, but not in B-lymphoma cells, and that the C-terminal half of the protein encoded by this gene is similar or identical to the corresponding regions of the proteins encoded by the clones reported by Yanagi *et al.*[14], Hedrick *et al.*[16] and Chein *et al.*[21]. Thus we can conclude that clone pHDS11 encodes the β-subunit of CTL 2C.

The gene defined by cDNA clones pHDS4 and pHDS203 is also expressed and rearranged specifically in T cells. This gene and the β-chain gene are clearly distinct and do not cross-hybridize in standard conditions, although they are related. At the protein level the pHDS4/203 sequence is approximately as closely related (16–23%) to immunoglobulin light and heavy chains as is the β-chain. About the same level (20%) of sequence identity exists between the pHDS4/203 protein and the β-chain. This relatively low overall sequence similarity, however, is somewhat misleading in that it overlooks the striking organizational similarity between the two proteins: each of them contains two

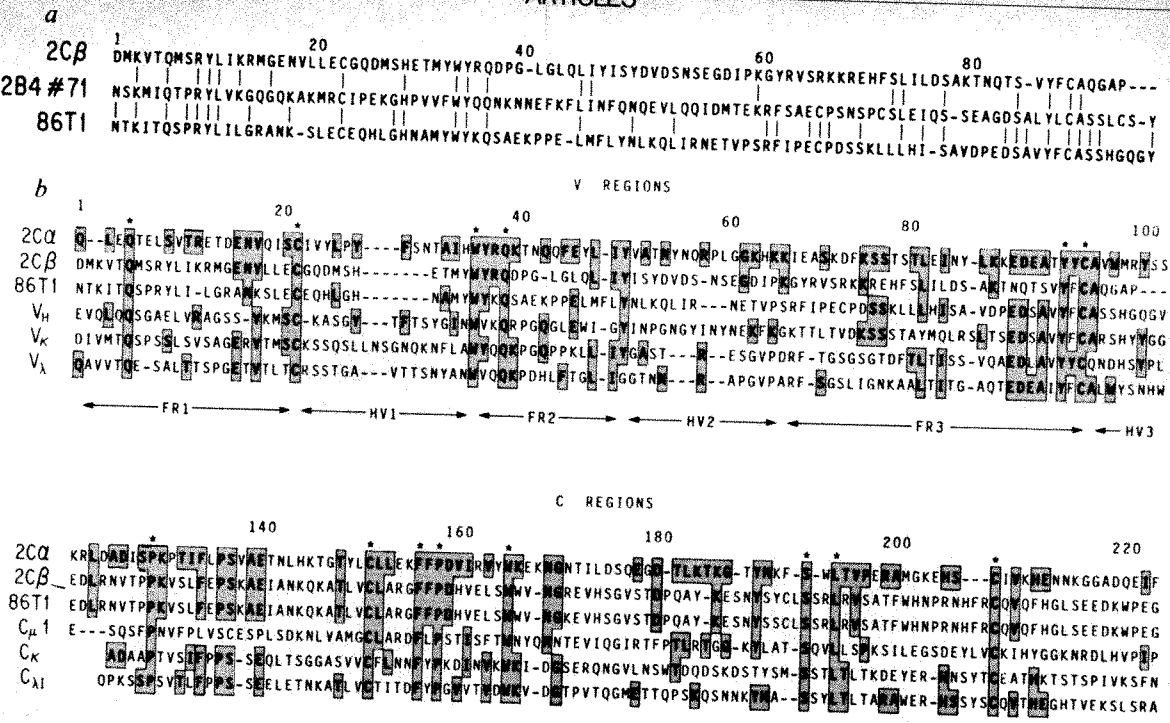

Fig. 5 *a*, Comparisons of the predicted amino acid sequences of three V_β regions, 2C β (pHSD11), 2B4.71 (ref. 21) and 86T1 (ref. 16). Those residues common between 2C β and 2B4.71, or 2B4.71 and 86T1 are indicated by vertical lines. *b*, Comparisons of the predicted amino acid sequence of pHDS4/203 (2C α) and predicted or determined amino acid sequences of five other proteins, the β-chain encoded by pHDS11, the β-chain encoded by cDNA clone 86T1 (ref. 16), the V regions of the 93G7 γ1 heavy chain[23], the C_H1 region of the μ heavy chain, the V and C regions of the MOPC603 κ chain[23] and the MOPC104E λ1 chain[23]. Those residues common between the 2C α polypeptide chain and any of the other five chains are shaded. The residues common among all six chains are indicated by *. Approximate boundaries of framework and hypervariable regions as they appear in immunoglobulin V regions are indicated by arrows.

immunoglobulin-like domains, a transmembrane peptide and a cytoplasmic peptide of similar sizes in the two chains. Earlier studies at the protein level indicated that the mouse receptor is composed of two different subunits of similar size held together by one or more disulphide linkage(s)[8–10]. In agreement with these findings, the predicted molecular weight (33K) of the pHDS4/203 protein is very similar to that (32K) of the β-chain encoded by pHDS11. Also, the pHDS4/203 protein and the pHDS11 β-chain each contain one Cys residue in corresponding positions (234 and 236, respectively) that lie outside the immunoglobulin-like domains. These residues can provide the postulated inter-chain disulphide linkage. Thus, while direct evidence is yet to be produced it is very likely that pHDS4/203 codes for the α-subunit of the CTL receptor.

Proposed structure of the T-cell receptor

The amino acid sequences deduced for the two subunits suggest the overall structure for the T-cell receptor shown in Fig. 7. In this model each receptor molecule is made up of two chains, each with two extracellular immunoglobulin-like domains, an amino-terminal variable and a carboxy-terminal constant domain. Each of these domains is stabilized by an S–S bond between cysteine residues that are separated in the linear sequence by 60–70 residues. Amino acid sequence similarity with immunoglobulin V regions (Fig. 5*b*) point to V (or V+D), D and J segments in the N-terminal domain of the α-subunit (Vα), as previously proposed for the corresponding domain of the β-subunit (Vβ)[16,21].

Cysteine residues at positions 234 and 236 of the α- and β-subunits, respectively, could well form a single inter-chain S–S bond located close to the cell outer membrane. This bond would link the two subunits in the intact molecule and account for the difference in apparent molecular weight between the unreduced and reduced receptor (90K compared with 40–45K) in SDS–polyacrylamide gel electrophoresis (PAGE). More important, a stable association between two different subunits may well be required to form an effective antigen-binding region, as is characteristic of immunoglobulins. The obligate participation of two different subunits in the formation of a single combining site means that combinatorial variability is likely to contribute to structural and functional diversity of these receptors.

The protein molecular weights of the α- and β-subunits are each about 10K less than the apparent molecular weight observed in SDS–PAGE. The difference suggests that the subunits are glycosylated. There are four potential sites for *N*-glycosylation of the β-subunit but none in the α-subunit. It is possible that the α-subunit is *O*-glycosylated on serine and threonine residues.

After the constant domain, each subunit has at its carboxyl end a hydrophobic stretch of 21–22 amino acids followed by a short stretch of 5(β) or 12(α) amino acid residues in which cationic residues abound. As these segments correspond, respectively, to the transmembrane and cytoplasmic domains that are characteristically found in transmembrane proteins, they support the proposed membrane location and receptor function of the gene products.

The presence of a cysteine residue in the cytoplasmic domain of the α-subunit might provide an SH group for dynamic

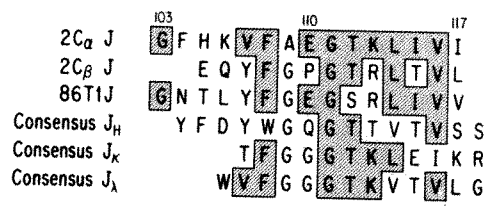

Fig. 6 Comparisons of the J region sequence of 2C α (predicted from pHDS4/203) and those of 2C β (predicted from pHDS11). 86T1 (ref. 16), and immunoglobulin J_H, J_κ, and J_λ (ref. 23) consensus sequences. Those residues common between 2C α J and any one of the other five J segments are boxed in and shaded.

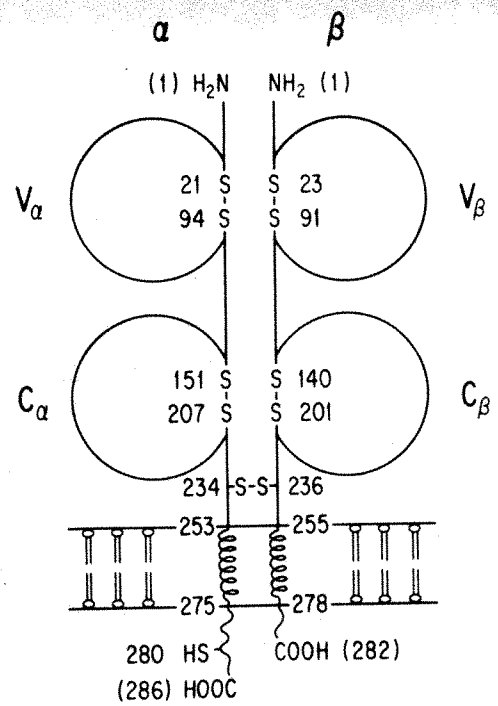

Fig. 7 Proposed overall structure of the 2C receptor. Each receptor molecule is made up of two chains, α and β, each with two extracellular immunoglobulin-like domains, an amino-terminal variable and a carboxy-terminal constant domain. Each of these domains is stabilized by an S–S bond between cysteine residues. Two chains are held by a single inter-chain S–S bond located close to the cell's outer membrane. The protein is anchored on the membrane by two (one for each chain) hydrophobic transmembrane peptides. A short carboxy-terminal peptide rich in cationic residues extends into cytoplasm in each chain. The SH group of the cystein residue present in the cytoplasmic peptide of the α-subunit may interact dynamically with a membrane or cytoplasmic protein and thereby may be important for the cell's effector function. Both α- and β-chains are glycosylated, although the exact site(s) and extent of glycosylation are unknown.

interactions between the receptor and other molecules of the cell membrane (such as T3 (ref. 9) in human CTL) or perhaps the cytoskeleton. The need for a functional association with such accessory structures is suggested by the overall resemblance of the proposed model to Fab fragments of immunoglobulin molecules: as is well known, these fragments have ligand-binding activity but lack effector functions.

These data throw light on the question of whether CTL and T-helper cell receptors are encoded by the same or separate sets of genes. We will consider the V and C regions separately because the two regions are encoded by distinct gene segments (ref. 21 and our unpublished observations). In immunoglobulin molecules the primary function of the V_H and V_L regions is, of course, to determine antigen specificity. Each of the multiple C_H regions defines an immunoglobulin class and carries a distinct effector function. The primary function of the C_L region is unclear. It is not required for antigen specificity but may be necessary to enhance L–H gene interactions or to facilitate some unknown function. In T-cell receptors the very presence of the V regions strongly suggests that these regions have a primary role in determining antigen and MHC specificity. An interesting question is whether the CTL and T-helper cell receptors carry distinct C regions each of which has a unique role in the activation or execution of the cell's effector function. An alternative view is that the receptors of the two types of T cells have the same C regions and that while the $\alpha\beta$ heterodimer is specific with regard to ligand binding it has only a nonspecific role in triggering the cell's effector functions.

Comparison of the β cDNA (clone pHDS11) from CTL clone 2C and the β cDNA (clone 2B4.71) from T-helper cell clone 2B4 indicates that at least these CTL and T-helper cells use the same C_β gene segment (clone 2C and clone 2B4 are from the BALB.B and B10.A strains, respectively, and the single base pair differences between their cDNAs may be due to a strain difference.) This conclusion is supported by two observations. First, the near identity of the two cDNA sequences occur not only in the C regions but also in the 3′ untranslated regions. Second, the J segments in the two cDNAs are different but belong to the same cluster linked to a single C gene segment[21]. While sequencing of more β genes is required before a firm conclusion can be drawn, these results already suggest strongly that the same C gene segments are used for β chains of CTL and T-helper cells.

Concerning the V regions, several earlier observations suggested that CTL and T-helper cell receptors use non-overlapping sets of gene segments that have evolved separately under different selective pressure: first, the antigen repertoires seem to be quite different; second, different classes of MHC gene products restrict CTL and T-helper cell responses; third, no clearly demonstrated case of T-cell reactivity that crosses the MHC class barrier has been reported (D. Raulet, personal communication). An alternative view is that CTL and T-helper cell receptors share a common pool of germ-line gene segments for V regions and that the distinction between function arises by somatic selection.

The amino acid sequences predicted by the 2C β cDNA (clone pHDS11) and 2B4 β cDNA (clone 2B4.71) are only similar at 21% of residues in the V (or $V+D$) segment-encoded regions (Fig. 5a). This is substantially lower than the similarity observed between any pair of immunoglobulin V_k segments (40–98%)[23] and is even less than that observed between the C_β region and the immunoglobulin C_k or $C_{\lambda 1}$ domain (22% and 31%, respectively)[16]. While characterization of more V_β regions is required before a firm conclusion can be drawn, the weakness of the similarity between the CTL V_β and T-helper cell V_β regions is striking and may reflect independent pools of V and/or D gene segments.

Finally, it will be extremely interesting to compare in similar fashion the V_α and C_α regions of CTL and T-helper cells. It is possible that, as in immunoglobulin molecules, the C region of only one of the two types of chains in these antigen-recognition molecules is involved in effector function.

We thank John McMaster, Ingrid E. Ehrmann and Howard Siegel for technical assistance, and Mrs Eleanor Basel for secretarial assistance. Molecular cloning of cDNA encoding a murine haematopoietic growth regulator, granulocyte–macrophage colony stimulating factor

Nicholas M. Gough*, Jill Gough*, Donald Metcalf†, Anne Kelso†, Dianne Grail*, Nicos A. Nicola†, Antony W. Burgess* & Ashley R. Dunn*

* Melbourne Tumour Biology Branch, Ludwig Institute for Cancer Research and † The Walter and Eliza Hall Institute of Medical Research, Post Office, Royal Melbourne Hospital, Victoria 3050, Australia

cDNA clones specifying the murine granulocyte–macrophage colony stimulating factor have been isolated. This haematopoietic growth factor is encoded by a unique gene specifying a messenger RNA of 1,200 nucleotides and a polypeptide of 118 amino acids. It bears no structural similarity to the functionally related factor, interleukin-3, described recently.

INDIVIDUAL multipotential stem cells can give rise to all of the different cell types of the haematopoietic and lymphoid systems[1]. Although this process is poorly understood, it has become apparent from *in vitro* studies that the proliferation, differentiation and functional activation of the various blood cells are controlled by a group of glycoprotein regulator factors including erythropoietin, T-cell growth factor (IL2) and the colony stimulating factors (CSFs)[2]. The colony stimulating factors which regulate the formation of neutrophilic granulocytes and macrophages have distinctive biological activities (M-CSF is a selective proliferative stimulus for macrophages[3]; G-CSF for granulocytes[4]; GM-CSF for both granulocytes and macrophages[5]), while multi-CSF—also known as interleukin-3 (ref. 6), burst-promoting activity[7], P-cell stimulating factor[8], mast cell growth factor[9] and haematopoietic cell growth factor[10]—stimulates the proliferation of not only neutrophilic granulocytes and macrophages, but also eosinophils, megakaryocytes, erythroid and mast cells[11]. Although it has been possible to purify all four colony stimulating factors, detailed analysis of many aspects of their biology and biochemistry has been hampered by the limited quantities available. This problem can be largely circumvented by molecular cloning of the corresponding gene sequences.

The present report describes molecular clones corresponding to GM-CSF. GM-CSF synthesized by mouse lung tissue is a glycoprotein of molecular weight 23,000 (ref. 5) which is active at low concentrations (10^{-11}–10^{-12} M) and is required continuously for the *in vitro* proliferation of progenitor cells of granulocytes and macrophages[2]. It also controls the irreversible commitment of these progenitors to the formation of granulocytes and macrophages[12] and can regulate the functional activity of the mature end cells[2]. A partial NH_2-terminal amino acid sequence has recently been determined for GM-CSF isolated from mouse lung-conditioned medium (L. Sparrow, D.M., T. Hunkapillar, L. Hood and A.W.B., manuscript in preparation). Using this partial amino acid sequence, oligonucleotides complementary to the putative GM-CSF mRNA were synthesized and used as probes to identify cDNA clones corresponding to the GM-CSF messenger RNA in a mouse lung cDNA library. From the nucleotide sequence of the cDNA clones, we deduced the amino acid sequence of GM-CSF and compared it with that recently reported for a functionally related growth factor, multi-CSF (interleukin-3)[13,14].

Isolation of GM-CSF clones

All mouse tissues contain and synthesize detectable amounts of GM-CSF, although the levels are extremely low[15]. To isolate a GM-CSF complementary DNA clone, we constructed a cDNA library using mRNA from the most active tissue available: lungs from mice injected with bacterial endotoxin[16]. The library was searched for GM-CSF clones by hybridization with synthetic oligonucleotides complementary to two short regions of the putative GM-CSF mRNA sequence, predicted from the partial NH_2-terminal amino acid sequence of the protein. We used oligonucleotide probes complementary to two different regions of the mRNA to help rule out irrelevant clones: whilst some clones may contain sequences fortuitously complementary to one of the oligonucleotide probes, a clone containing the GM-CSF sequence would be expected to hybridize to both. Figure 1 shows the GM-CSF amino acid sequence between residues 7 and 16, the possible combinations of nucleotide sequences that could encode this peptide and the oligonucleotides that were used as hybridization probes. As the assignment of amino acid 9 was equivocal (being either histidine or cysteine), two different sets of oligonucleotides encompassing this region were synthesized; probe 1 assumes a histidine and probe 2 a cysteine residue. The second region chosen within the amino acid sequence required an extremely degenerate set of oligonucleotides which were synthesized as two 48-fold degenerate sets (probes 3 and 4).

In the initial screening, all four sets of oligonucleotide probes were used as a mixture (see legend to Fig. 1); screening of ~100,000 cDNA clones yielded 22 positives, of which two (pGM37 and pGM38) hybridized separately with probe 1 and with a mixture of 3 plus 4 and were therefore strong candidates to contain sequences coding for GM-CSF. In order to confirm their identity, we asked whether transcripts complementary to these cloned sequences were present in cells that synthesize GM-CSF; whether DNA from these clones could specifically select, by hybridization, biologically active GM-CSF mRNA; and whether the nucleotide sequence of the clones could encode the known GM-CSF protein sequence.

Detection of GM-CSF mRNA

Initially we determined whether the abundance of transcripts corresponding to pGM38 in various cell types paralleled the ability of those cells to synthesize GM-CSF. Messenger RNA from mouse lung (which synthesizes GM-CSF) and from various cells which do not synthesize GM-CSF was fractionated on formaldehyde–agarose gels, transferred to nitrocellulose and hybridized with a probe derived from pGM38. Figure 2 shows that this probe detected a low abundance transcript of about 1.2 kilobases (kb) in mRNA from mouse lung (lane 3), but not in mRNA from several randomly selected cell lines which do not synthesize GM-CSF, including the thymoma-derived cell line TIKAUT (lane 1) and the plasmacytoma P3 (lane 2). Furthermore, this probe failed to detect any transcript in mRNA from WEHI-3B D^- (lane 6), RIII (lane 7) and L cells (lane 8), which synthesize multi-CSF[6], G-CSF (N.A.N., G. R. Johnson and R. H. Whitehead, unpublished results) and M-CSF[3] respectively. The very low abundance of the transcript corresponding

to pGM38 in lung mRNA was not surprising given the low frequency of pGM38-related cDNA clones in the lung cDNA library (~1 in 50,000).

As a more critical test of whether transcripts complementary to pGM83 correlated with GM-CSF production, we used a cloned T lymphocyte cell line (LB3)[17] in which the synthesis of both GM-CSF and multi-CSF is induced by concanavalin A (A.K., D.M. and A.W.B., unpublished results). Figure 2 shows that the pGM38-derived probe detected an abundant mRNA in LB3 cells that had been stimulated with concanavalin A (lane 5) but failed to detect any transcript in mRNA from unstimulated LB3 cells (lane 4). As the probe used does not hybridize to the multi-CSF mRNA in WEHI-3B D⁻ (lane 6), it is likely that pGM38 hybridized to the GM-CSF mRNA in LB3 cells.

Synthesis of GM-CSF in *Xenopus* oocytes

As a direct test of the identity of pGM38, we sought to establish whether this cDNA could specifically select, by hybridization, biologically active GM-CSF mRNA. GM-CSF mRNA was identified by translation in *Xenopus* oocytes and the culture medium assayed for ability to stimulate granulocyte/macrophage proliferation in three microculture systems: (1) liquid cultures containing purified fetal liver haematopoietic progenitor cells, which respond directly to all four colony stimulating factors[18,19]; (2) micro-agar cultures containing bone marrow cells, in which the formation of morphologically identifiable granulocyte and macrophage colonies can be stimulated by all four colony stimulating factors; and (3) liquid cultures containing the factor-dependent mast cell line, 32D C13 (ref. 20), which responds to multi-CSF but not GM-CSF[21]. From this set of assays, GM-CSF and multi-CSF can be unambiguously distinguished.

Initially we tested whether pGM38 DNA could select GM-CSF mRNA from mouse lung RNA. After injection of unfractionated lung mRNA or mRNA selected by hybridization to pGM38 DNA into *Xenopus* oocytes, very low levels of CSF activity could be detected in the culture media, a finding that was anticipated from the very low abundance of mRNA corresponding to pGM38 in mouse lung (Fig. 2). By contrast, mRNA from concanavalin A-stimulated LB3 cells (which synthesize both GM- and multi-CSF) is rich in mRNA corresponding to pGM38 (Fig. 2) and, on injection into *Xenopus* oocytes, reproducibly directed the synthesis of high levels of material stimulating the proliferation of fetal liver and 32D C13 cells (Fig. 3). Triplicate filters containing either pGM38 or vector DNAs were therefore challenged with concanavalin A-stimulated LB3 mRNA in a hybrid-selection experiment (see legend to Fig. 3). Figure 3*a* shows that medium from oocytes injected with mRNA selected by pGM38 DNA strongly stimulated fetal progenitor cell proliferation with the development of maturing granulocytes and macrophages (Fig. 4). These oocyte-conditioned media also stimulated typical[22] granulocyte–macrophage colony formation in micro-agar cultures (18% granulocyte, 53% mixed granulocyte–macrophage and 29% macrophage colonies). In neither assay was there evidence that these oocyte-conditioned media stimulated the proliferation of erythroid, megakaryocytic or eosinophilic cells, hence the active factor appeared to be GM-CSF rather than multi-CSF. In confirmation of this conclusion, these oocyte-conditioned media were found to be incapable of stimulating proliferation of 32D C13 cells (Fig. 3*b*). Vector DNA alone failed to select mRNA corresponding to GM-CSF or multi-CSF (Fig. 3*a*, *b*).

Taken together, these data indicate that pGM38 DNA can specifically select a mRNA encoding a factor with the unique biological characteristics of GM-CSF from a mixture containing both GM-CSF and multi-CSF mRNAs.

Nucleotide sequence of GM-CSF mRNA

Nucleotide sequence analysis of the cDNA portion of pGM37 and pGM38 revealed that these two clones, which contain sequences complementary to overlapping portions of the same mRNA, contain the putative GM-CSF mRNA sequence. The relationship between the cDNA portion of the two clones and

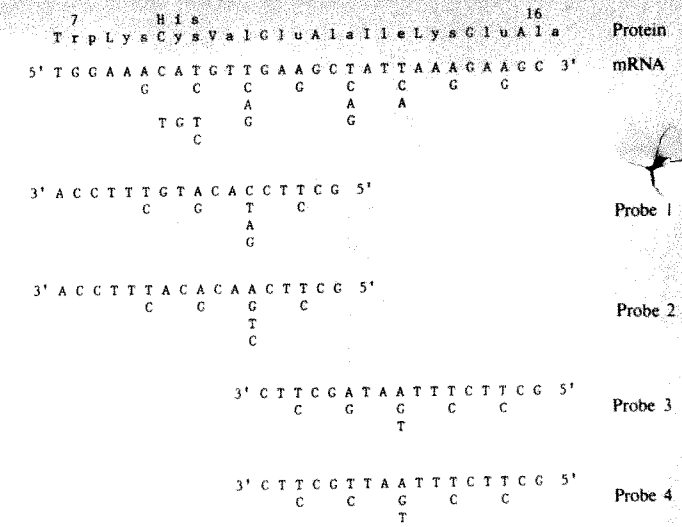

Fig. 1 Synthetic oligonucleotides used for identifying GM-CSF clones. A portion of the amino acid sequence of murine GM-CSF (residues 7–16) is shown on the top line, the possible combinations of nucleotide (mRNA) sequences that could encode this peptide segment in the middle, and the four different sets of oligonucleotide probes complementary to regions of this mRNA sequence below. **Methods:** The methods used for the construction and screening of the lung cDNA library were as follows. Ninety C57BL/6 mice were injected intravenously with bacterial endotoxin (5 μg per mouse) and after 3 h the lungs were removed and cultured *in vitro* in serum-free Dulbecco's modified Eagle's medium[16]. Total cellular RNA was extracted, essentially as described in ref. 42, from batches of 30 pairs of lungs after 0, 5 and 15 h of culture, pooled and then poly(A)-containing RNA prepared by oligo(dT)–cellulose chromatography. A duplex DNA copy of the pooled lung mRNA was synthesized using avian myeloblastosis virus reverse transcriptase for synthesis of the first-strand and *Escherichia coli* DNA polymerase I (Klenow fragment) for synthesis of the second strand, using standard techniques[43,44]. After cleavage of the hairpin loop with S_1 nuclease, oligo(dC) tails (approximately 20–30 residues per end) were added using terminal deoxynucleotidyltransferase[45]. The tailed cDNA was fractionated by electrophoresis on a 1.5% agarose gel and molecules greater than 500 bases in length recovered and annealed to dG-tailed plasmid DNA. The plasmid used (pJL3) is an SV40-based expression vector (J.G., N.M.G and A.R.D., manuscript in preparation) that contains the β-lactamase gene and origin of DNA replication from pAT153, the SV40 origin of DNA replication and T-antigen coding sequences and a multi-cloning site adjacent to the SV40 late promoter. *E. coli* MC1061 (ref. 46) was transformed with the annealed cDNA–plasmid mixture using a high efficiency transformation procedure (J.G., unpublished) that yields $>10^8$ transformants per μg of vector DNA. Pools containing approximately 2,000–3,000 ampicillin-resistant clones were stored in 10% glycerol at −70 °C. For screening by colony hybridization, approximately 4,000 bacterial colonies from each pool were grown on agar plates (containing 40 μg ml^{-1} ampicillin), transferred to nitrocellulose filter disks and plasmid DNA amplified by incubation of the filter on agar plates containing 200 μg ml^{-1} chloramphenicol[47]. After regrowth of colonies on the original plate, a second nitrocellulose filter was prepared. The master plate was regrown a second time and then stored at 4 °C. Plasmid DNA was released from the bacterial colonies and fixed to the nitrocellulose filters[19]. Before hybridization, filters were incubated for several hours at 37 °C in 6×SSC (SSC = 0.15 M NaCl, 0.015 M sodium citrate), 0.2% Ficoll, 0.2% polyvinyl-pyrrollidone (PVP), 0.2% bovine serum albumin (BSA) containing 50 μg ml^{-1} of denatured salmon sperm DNA and 10 μg ml^{-1} of denatured *E. coli* DNA. Hybridization was in the same solution, containing 0.1% NP40, at 37 °C for about 18 h. The synthetic oligonucleotides (kindly supplied by S. Horvath and L. Hood) were radioactively labelled using [γ-^{32}P]ATP and polynucleotide kinase and each was present in the hybridization reaction at 1.5 ng ml^{-1}. After hybridization, filters were extensively washed in 6×SSC, 0.1% SDS at 42 °C and then autoradiographed. Colonies positive on duplicate filters were picked and rescreened at low density as before.

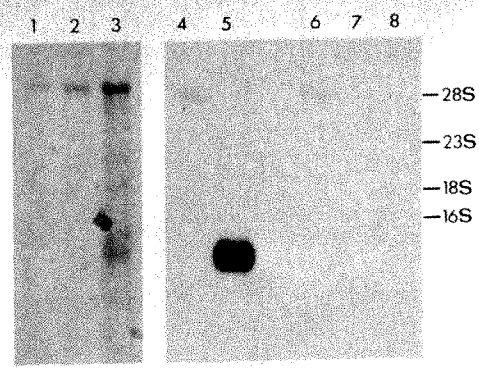

Fig. 2 Detection of GM–CSF mRNA in various cells. 5 μg of poly(A) RNA from TIKAUT (lane 1), P3 (lane 2), mouse lung (lane 3), unstimulated LB3 (lane 4), concanavalin A-stimulated LB3 (lane 5), WEHI3B D⁻ (lane 6), RIII (lane 7) and L cells (lane 8) were electrophoresed on 1% formaldehyde/agarose gels, transferred to nitrocellulose and hybridized with a fragment of DNA spanning the entire insert of pGM38 ^{32}P-labelled by nick-translation[48]. Hybridization was at 65 °C for 16 h in 2×SSC, 0.1% SDS, 0.2% Ficoll, 0.2% PVP, 0.2% BSA containing 50 μg ml^{-1} of denatured salmon sperm DNA. LB3 (formerly B3)[24] is a cloned Thy-1$^+$, Lyt-2$^-$, MT4$^+$ T lymphocyte line derived from BALB/c anti-DBA/2 mixed leukocyte culture, and maintained by weekly passage with irradiated DBA/2 spleen cells (1,500 R) in the presence of interleukin-2. Concanavalin A-stimulated LB3 cells were prepared by culturing cells at 10^6 per ml with 5 μg ml^{-1} concanavalin A in tissue culture medium with 5% fetal calf serum for 5 h. The molecular weight markers used and their presumed molecular weights were: mammalian 28 and 18S rRNA (4,700 and 1,800 nucleotides) and *E. coli* 23 and 16S rRNA (2,904 and 1,541 nucleotides). A low level of hybridization to residual 28S rRNA is evident after long autoradiographic exposure (tracks 1–3).

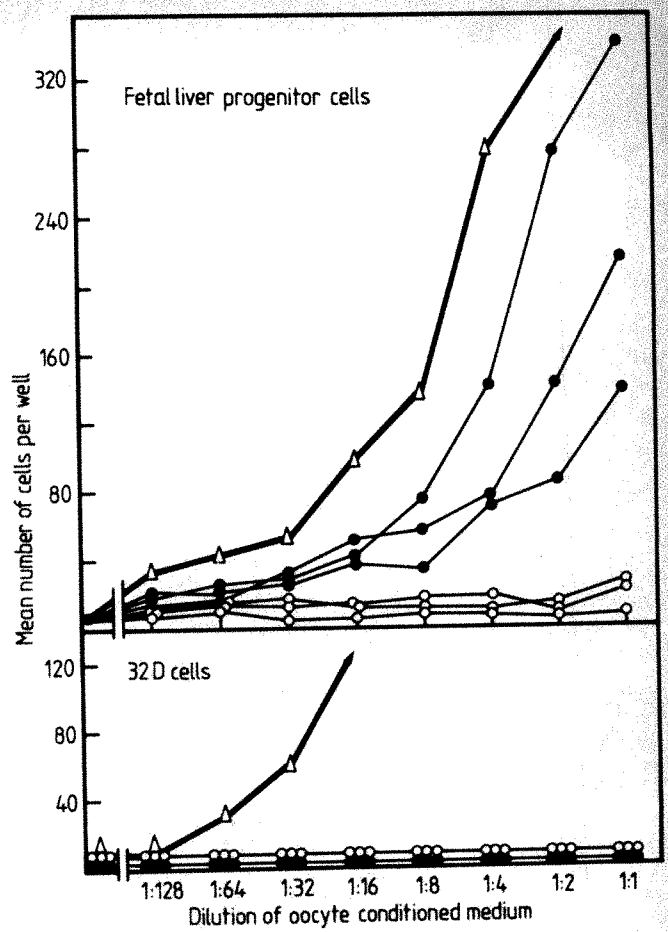

Fig. 3 Stimulation of cellular proliferation in suspension cultures of haematopoietic progenitor cells from fetal liver (upper panel) and multi-CSF-dependent 32D C13 cells (lower panel) by medium from mRNA-injected *Xenopus* oocytes. Unfractionated LB3 mRNA is indicated by heavy lines. ●—●, mRNA selected by hybridization to pGM38 DNA; ○—○, that selected by vector DNA alone; the three separate curves represent triplicate experiments. **Methods:** Hybrid selection was performed essentially as described elsewhere[49]. pGM38 or vector (pJL3) DNA (5-μg aliquots) were bound to small squares of nitrocellulose and incubated with 1–2 μg aliquots of concanavalin A-stimulated LB3 mRNA in 50% formamide, 0.5 M Tris-HCl *p*H 7.5, 0.75 M NaCl, 0.002 M EDTA, 0.4% SDS, 10 μg ml^{-1} *E. coli* tRNA in a reaction volume of 30 μl at 37 °C for 16 h. After incubation, filters were exhaustively washed in hybridization buffer at 37 °C and then in 10 mM Tris-HCl *p*H 7.5, 2 mM EDTA at 52 °C. Bound RNA was eluted by boiling for 1 min in 300 μl 10 mM Tris–HCl *p*H 7.5, 2 mM EDTA containing 1.5 μg of *E. coli* tRNA. RNA was precipitated by addition of sodium acetate and ethanol and chilling at −20 °C for 16 h. After centrifugation, precipitated RNA was washed with cold 70% ethanol, dried and redissolved in 1.5 μl 1 mM Tris–HCl *p*H 7.5, 0.1 mM EDTA. For each RNA sample, groups of 30 *Xenopus* oocytes were injected with 50 nl of RNA per egg. Unfractionated LB3 mRNA was at 1 μg ml^{-1} for injection and 50 nl was injected per egg. After incubation of injected oocytes for 4 days, oocyte culture medium was diluted 1:2 in medium containing 5% fetal calf serum, filtered and 5-μl volumes assayed in serial dilutions in 15-μl cultures containing 200 fluorescence-activated cell sorter fractionated 14 day CBA fetal liver progenitor cells[18] or 200 32D C13 cells[20]. Each point is the mean cell count from duplicate cultures after 2 days of incubation.

the mRNA is shown in Fig. 5*a*. The nucleotide sequence given in Fig. 5*b* is a composite derived from both clones. A stretch of 20 adenosine residues, corresponding to the poly(A) tail of the mRNA, preceded by the hexanucleotide AATAAA (found toward the 3′ terminus of most eukaryotic mRNAs[23]) is present at one end of pGM38. This allowed us to orient the sequences of the cDNA clones with that of the mRNA.

The sequence presented in Fig. 5*b* contains a single large open reading frame of 354 nucleotides; the amino acid sequence predicted by this region is presented from the first residue of the mature protein and is given above the nucleotide sequence. From residues 2 to 29, the amino acid sequence is identical (but for four residues) with the partial NH_2-terminal amino acid sequence for GM-CSF (L. Sparrow *et al.*, manuscript in preparation), which is shown above that predicted by the cDNA. Of the four discrepancies, two of the residues (20 and 24) had been only tentatively assigned in the sequence of the protein. The first residue of the mature peptide, which could not be determined in the protein sequence, is predicted by the nucleotide sequence to be isoleucine. The primary structure of the protein deduced from the nucleotide sequence has a molecular weight of 13,500, which is in good agreement with the apparent molecular weight of 16,800 for GM-CSF extensively deglycosylated with endoglycosidase F (A.W.B., unpublished results). Two potential *N*-glycosylation sites (Asn–X–Thr)[24] which occur within the predicted amino acid sequence, are indicated in Fig. 5*b* by asterisks.

pGM37 extends 20 nucleotides 5′ to the first position presented in Fig. 5*b* and does not contain an initiation codon; several hydrophobic amino acids are contained within this region (not shown), a characteristic of signal peptides of secreted proteins[25]. The size of the GM-CSF mRNA is ~1,200 nucleotides (Fig. 2), of which ~150 nucleotides are probably contributed by the poly(A) tail[26]. The 3′ untranslated region is 319 nucleotides and the region encoding the mature protein 354 nucleotides (Fig. 5*b*). Thus some 350 nucleotides remain for the putative NH_2-terminal signal peptide and the 5′ untranslated region.

There are three discrepancies between the nucleotide sequences derived from the two cDNA clones (positions 237, 346 and 507), one of which (position 346) causes an amino acid sequence ambiguity (Gly or Ser at amino acid residue 116). As the mice (C57BL/6) from which the cDNA clones were isolated are highly inbred and hence should be homozygous at the GM-CSF locus, and as there appears to be only one gene encoding GM-CSF in the mouse germ line (see below), it is

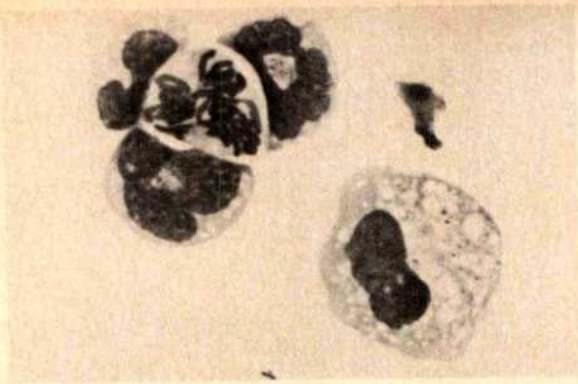

Fig. 4 Four-day suspension culture of purified fetal liver haematopoietic progenitor cells after stimulation by medium from oocytes injected with pGM38-selected mRNA from LB3 cells. Note mitotic activity and the production of maturing granulocytes and macrophages.

likely that these three sequence ambiguities reflect artefacts created during cDNA synthesis[27], and indeed reverse transcriptase has an error frequency on synthetic polynucleotides of approximately one in 600 nucleotides (ref. 28).

GM-CSF is encoded by a unique gene

As there are known to be multiple molecular forms of GM-CSF isolated from various mouse organs[29], we tested how many genes the GM-CSF cDNA could detect in the murine genome. BALB/c embryo or C57BL/6 liver DNA digested with various restriction endonucleases was fractionated on agarose gels, transferred to nitrocellulose[30] and hybridized with a fragment containing the entire cDNA insert in pGM38. In both mouse strains, a single *Eco*RI fragment (Fig. 6, lanes 1, 2), a single *Pst*I fragment (lanes 3, 4) and a single *Bam*HI fragment (not shown) were detected. Since the *Pst*I fragment is only 2.5 kb in length it is unlikely that this fragment could accommodate more than one gene. We therefore conclude that there is only one gene encoding the lung-type GM-CSF in the mouse germ line, barring the unlikely possibility that two (or more) genes are flanked by identically positioned *Eco*RI, *Pst*I and *Bam*HI restriction sites.

Figure 6 also reveals that the GM-CSF gene is contained within the same *Eco*RI fragment in DNA from concanavalin A-stimulated LB3 cells (lane 6) as in embryo DNA (lane 5). No additional bands were evident in LB3 DNA nor was the intensity of hybridization different from that of embryo DNA, from which we infer that there are no alterations in the copy number or gross changes in the context of the GM-CSF gene in cells which synthesize large quantities of GM-CSF.

In order to determine the chromosome on which the GM-CSF gene resides, we examined DNA from seven mouse–Chinese hamster hybrid cell lines which retain various mouse chromosomes (see Table 1 in ref. 31). Southern analysis of the cell lines (not shown) indicated that the 22 kb *Eco*RI fragment present in the murine genome was absent from every hybrid cell line. As chromosome 11 is the only mouse chromosome not retained in any of these lines[31] (a characteristic of mouse–Chinese hamster hybrids[32]), we conclude that the GM-CSF gene is likely to be located on this chromosome. The GM-CSF gene is therefore unlikely to be linked to the four loci in the mouse, *Sl*, *W*, *an* (ref. 33) and *op* (ref. 34), which are involved in the control of haematopoietic stem cell development and which are located on chromosomes 10, 5, 4 (ref. 33) and 12 (ref. 35) respectively.

Comparison with other growth factors

Four distinct colony stimulating factors with distinguishable biochemical and biological properties have been found to act within the granulocyte–macrophage pathway. Furthermore, multiple molecular forms of each of these factors have been observed[16,35–37]: the GM-CSF extracted from various mouse organs have different physical properties[16]; indeed, it has been

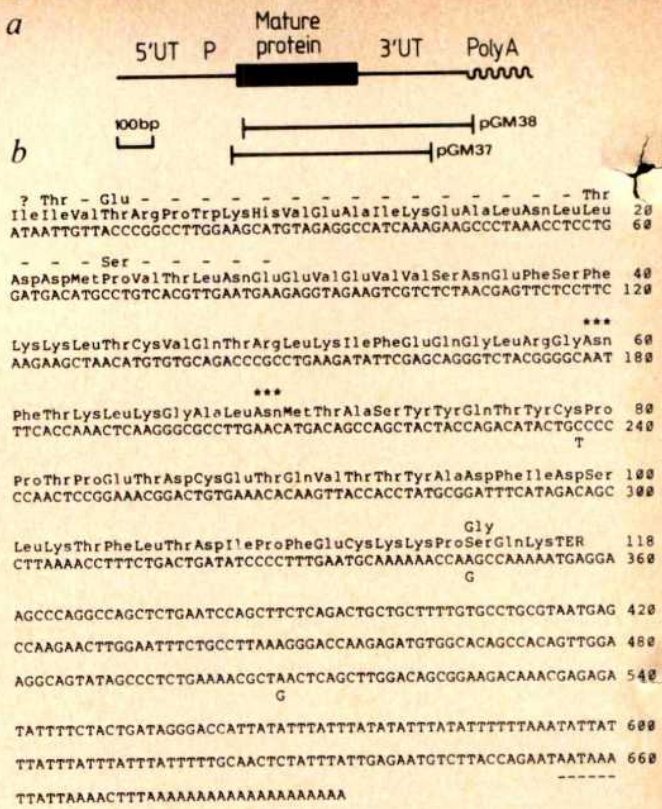

Fig. 5 *a*, Map of the GM-CSF mRNA and of clones pGM37 and pGM38. The mRNA is taken to be 1,200 nucleotides in length. The region of the mRNA encoding the mature protein is shown as a thick line. The untranslated regions are designated by UT and a putative precursor peptide by P. The regions contained within clones pGM37 and pGM38 are indicated with bars. pGM38 extends from nucleotide 14 in the sequence presented in *b* to the poly(A) tail, whereas pGM37 extends from 20 nucleotides 5′ to the sequence presented to position 574. *b*, Nucleotide sequence of GM-CSF mRNA. DNA fragments subcloned in M13 vectors[50] were sequenced by the chain-termination method using dideoxynucleoside trisphosphates[51]. Sequencing reactions were electrophoresed on thermostatically-controlled, 0.2 mm thick, 8% (w:v) polyacrylamide gels[52]. The nucleotide sequence given is a composite of sequence derived from clones pGM37 and pGM38; at three positions where the pGM37 nucleotide sequence differs from that of pGM38 the pGM37 alternatives are given below the line. The sequence of the mRNA-synonymous strand is listed 5′ to 3′, with the predicted amino acid sequence of GM-CSF given above; numbers at the ends of lines indicate the position of the final residue (amino acid or nucleotide) on that line. The partial amino acid sequence determined by L. Sparrow *et al.* (manuscript in preparation) for GM-CSF is indicated above the sequence derived from the clones; at positions where there is no discordance between the two, dashes are given. The first amino acid residue, determined by analysis of the protein, could not be assigned, and is indicated by a question mark. Potential *N*–glycosylation sites[24] are indicated with asterisks, and the putative polyadenylation signal[23] is underlined.

suggested that the GM-CSF produced by T lymphocytes may also represent a distinct form[38]. However, after appropriate treatment to reduce carbohydrate and charge heterogeneity, the GM-CSF from different organs have been shown to have nearly identical biological and biophysical properties[15]. Nonetheless, it is still unclear whether they represent products of multiple related genes or a single gene product with post-translational modifications. However, as we have shown here that there is only one gene in the mouse germ line corresponding to the lung-type GM-CSF, it is highly likely that the differences in the GM-CSF produced by different adult organs reflect post-translational modifications of a single product. Moreover, since the lung-derived GM-CSF cDNA can hybridize to the GM-CSF mRNA in the T-cell line LB3, this T-cell derived GM-CSF must be

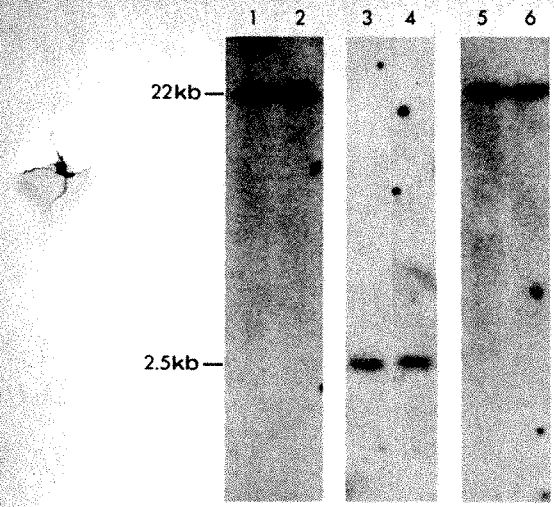

Fig. 6 Detection of the GM-CSF gene. DNA (20 μg) was digested with *Eco*RI (lanes 1, 2, 5, 6) or *Pst*1 (lanes 3, 4) and electrophoresed on 0.8% agarose gels. After transfer to nitrocellulose[29], the filters were hybridized with a fragment spanning the entire cDNA insert of pGM38, ^{32}P-labelled by nick-translation[23]. Hybridization was at 65 °C for 16 h in 2×SSC, 0.1% SDS, 0.2% Ficoll, 0.2% PVP, 0.2% BSA containing 50 μg ml^{-1} of denatured salmon sperm DNA. The DNA used in lanes 1, 3 and 5 was from 10 day old BALB/c mouse embryos, that in lanes 2 and 4 from C57BL/6 livers and that in track 6 from concanavalin A-stimulated LB3 cells (see legend to Fig. 2). Fragment sizes are given in kilobases and were determined[53] by reference to a *Hin*dIII digest of bacteriophage λ DNA.

encoded by the same gene as the lung-type GM-CSF. Variants with different amino acid sequences from that of the lung-type GM-CSF, and whose genes do not cross-hybridize with the lung-type GM-CSF, may of course exist.

It is intriguing to compare the sequence of GM-CSF with that of multi-CSF which, in addition to its other activities, has similar actions to GM-CSF in stimulating the growth of granulocyte and macrophage colonies from committed progenitor cells[11,35]. It might not have been surprising if these two factors had shown primary amino acid sequence similarity, reflecting a common receptor binding site or similar modes of action within the cell. This is, however, not the case. When we compared the amino acid sequence of GM-CSF (Fig. 5*b*) with that for murine multi-CSF[13,14] using the ALIGN computer program[39], we found only one cluster of three consecutive amino acids in common between GM-CSF and multi-CSF: Thr-Leu-Asn at position 26–28 of GM-CSF and 40–42 of multi-CSF. The dissimilarity of these two regulators is emphasized further by the differences in the predicted secondary[40] and tertiary[41] structures. Whereas GM-CSF is predicted to contain two long α-helical segments towards the NH_2-terminus of the molecule (from residues 7–22 and 25–40), the only notable α-helix predicted in multi-CSF is towards the C-terminus (residues 123–132). Furthermore, the hydrophilicity profiles for the two molecules are quite different, suggesting that their surface structures bear little resemblance to one another. Thus it would appear that GM-CSF and multi-CSF represent an example where similar biological activities have arisen by convergent evolution.

The apparent structural dissimilarity of GM-CSF and multi-CSF suggests that they may have different receptor binding sites; indeed, the simplest model would be that these binding sites represent two independent receptors. In this model, a cell responsive to both GM-CSF and multi-CSF would have both receptors, either of which when triggered would stimulate proliferation and differentiation, whereas a cell responsive only to multi-CSF would have a receptor only for this factor. However, this model is complicated by the observation that multi-CSF can compete efficiently with GM-CSF for binding to its receptor on bone marrow cells (F. Walker and A.W.B., unpublished results), suggesting that GM-CSF and multi-CSF may in fact interact with the same receptor.

As the molecular cloning of the murine GM-CSF mRNA sequence should facilitate the production of larger quantities of this regulator molecule than previously available, it should be possible to study in detail the interaction of GM-CSF with its receptor(s) and the signals thus generated. Moreover, by *in vitro* mutagenesis it should be possible to dissect the active site(s) of the molecule and to ask whether the different activities of GM-CSF—survival, proliferation and differentiation of progenitor cells—are determined by the same or different active sites.

We thank Felicity Drouet for her contributions to the early stages of this project; Suzanna Horvath, Lee Hood, Suzanne Cory, Uta Francke and Tom Gonda for providing certain materials; Tom Gonda and Joe Sambrook for useful discussions, Sue Blackford for preparation of the manuscript and Cathy Quilici for technical assistance. This work was supported in part by grants (to D.M., N.A.N. and A.K.) from the Carden Fellowship Fund of the Anti-Cancer Council of Victoria, the NH and MRC (Canberra) and the NIH (Bethesda) (grant CA22556), by a Queen Elizabeth II postdoctoral fellowship to A.K. and by an NH and MRC 'C. J. Martin' postdoctoral fellowship to N.M.G.

Red component activity in dwarf novae

R. Whitehurst, G. T. Bath & P. A. Charles

Department of Astrophysics, University of Oxford, South Parks Road, Oxford OX1 3RQ, UK

SU Ursae Majoris systems are short-period binary dwarf novae characterized by two distinct classes of outbursts: 'normal outbursts' of duration ~2 days and less frequent 'superoutbursts' which last ~12 days. Superoutbursts may be present in longer-period systems but could be classified as wide outbursts[1]. Superoutbursts require enhanced mass transfer rates for an extended period of ~10 days to explain their sustained activity[2,3]. During superoutbursts, 'superhumps' are observed[4–6] which modulate the visible light by ≲40% with a period 3–7% longer than the binary period. Measurement of eclipse depths in the two eclipsing SU UMa systems during superoutburst should show whether or not the superhump light is eclipsed and hence make it possible to infer its location either in the eclipsed disk or in the uneclipsed red component. Study of the available eclipse data reported here shows that the superhump light is not eclipsed, so that the red component is the location of the superhump.

Several models[4,7,8] locate the superhump in the vicinity of the accretion disk. Hence the superhump is at least partially eclipsed at the superhump maximum. Furthermore, models based on eccentric structure of the outer disk have significant difficulties on dynamical grounds[9,10]. The red-component superhump model due originally to Warner[5] and also suggested by Vogt[6] and Bath *et al.*[11] places the superhump on the red star and it would not be eclipsed (Fig. 1).

The eclipse acts as a 'stroboscope', revealing the brightness of the non-eclipsed material at various phases of the superhump light. In models where the superhump light is eclipsed the brightness at mid-eclipse will be unchanged by the passage through superhump maximum. A non-eclipsed superhump would cause the eclipsed light level to rise simultaneously with the out-of-eclipse superhump light[11]. The profile of the non-eclipsed light against superhump phase can be mapped using data from several eclipses.

The data analysed are those of Warner[4], and Krzeminski (see ref. 12). We have examined data for Z Chamaeleontis from three superoutbursts, January 1973, February 1980 and December 1982, all observed by Warner at the SAAO[4,5,13]. Plotting the excess light at mid-eclipse relative to the total light of the system (well away from both eclipses and superhumps), against the superhump phase we obtain Fig. 2*a* (see Table 1). Note that this has been corrected for the effect of the fading of the non-eclipsed material[4]. The feature remaining corresponds to both the shape and amplitude of the superhump in Z Cha, as is shown in the typical light curve in Fig. 2*b*. This result demonstrates conclusively that the superhump is uneclipsed in Z Cha at mid-eclipse.

The only other eclipsing SU UMa star, OY Carinae, was observed in superoutburst in January 1980 by Krzeminski. Vogt[12] measured the eclipse depths in magnitudes (relative to the light just out of eclipse) rather than intensities. The result of his method of analysis is that: (1) for eclipsed superhumps the relative eclipse depths will vary in phase with the total superhump light with a maximum at superhump maximum; (2) non-eclipsed superhumps will cause eclipse depths which will vary out of phase with the total superhump light and show a minimum at superhump maximum. The behaviour observed for OY Car[12] is compatible with case (2), and an uneclipsed origin for the superhump light.

Thus, in both observed eclipsing systems the superhump light is visible at mid-eclipse. This is most naturally accounted for as being due to an active, luminous region on the red component, rotating more slowly than the orbital period. The red component then contributes between 20 and 40% of the optical outburst light in an asymmetric 'superspot' region.

If the superhump light originates in the outer rim of the disk it can still be visible at mid-eclipse (except if located close to the line of centres). This light would still be eclipsed, however, and broaden the eclipse, or produce breaks in the eclipse profiles comparable to those visible in quiescent eclipse profiles[13] (produced in the quiescent case by the orbital hump visible in the light curve of these systems). Because such features are not evident in the superhump eclipse profiles we conclude that the superhump light is entirely uneclipsed.

The observations of Z Cha and OY Car made in superoutburst indicate that the eclipse minima vary from their expected times of minima in a manner dependent on the superhump phase at eclipse[4,12]. When presented as O–C (the difference between observed, O, and calculated, C, times of mid-eclipse) diagrams of phase of eclipse minimum versus superhump phase,

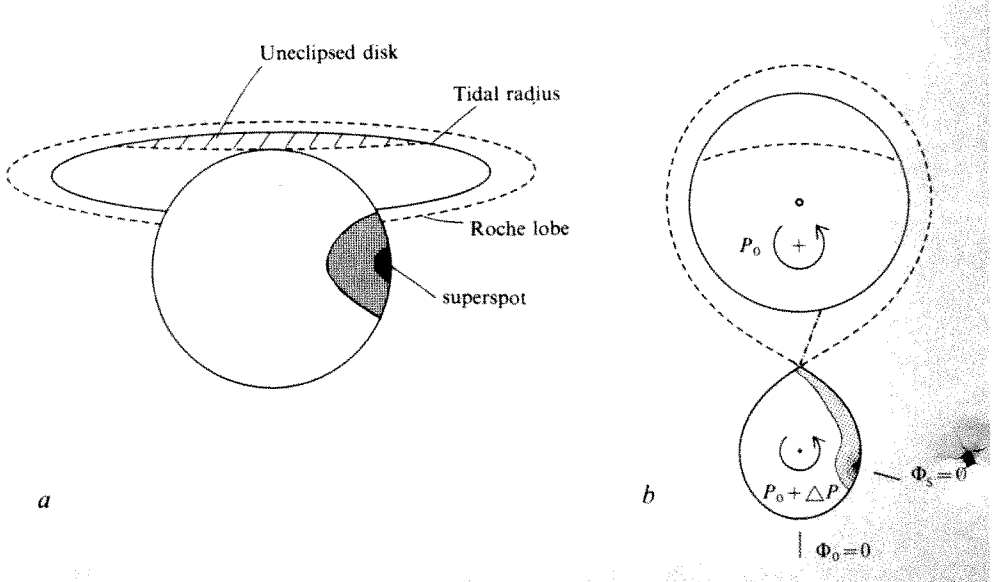

Fig. 1 Structure of the cataclysmic variable Z Chamaeleontis. Parameters used are those due to Vogt[12], and are the most probable for this sytem. *a*, An Earth-bound oberver's view at mid-eclipse, at superhump phase $\phi_s \simeq 0.35$. The extent of the uneclipsed disk surface is shown shaded above the dashed line. Any disk origin for superhumps must be located in this region at all times. A red-component superhump model has no such limitation. The Roche limit is indicated along with the best observational evidence for the disk tidal radius. *b*, The structure present during outburst. Superhump maximum at $\phi_s = 0$ migrates round in orbital phase through non-synchronism, and possibly additional changes in azimuthal structure. When superhump maximum coincides with mid-eclipse the superhump light remains visible.

Table 1 Data from Z Cha during three superoutbursts

Superoutburst	Date	Age of superoutburst (days)	Superhump phase	Relative excess light	Refs
January 1973	8	6.0	−0.32	−0.03	5,13
		6.05	−0.35	−0.02	
		6.1	−0.39	−0.02

		7.05	0.25	0.14	

the times of minima show two effects: an oscillation correlated with superhump phase, and a constant shift. In the data for OY Car, presented in five colours by Vogt[12], both of the above effects are present, and in the case of OY Car find a natural explanation with a red component origin for the superhump light.

A possible explanation of the constant shift has been suggested by Warner[4]. The constant displacement is most naturally due to an asymmetry in the luminosity of the disk due to stream impact and penetration. This displacement of the eclipse minima can be explained by allowing the following lune of the accretion disk to have a luminosity about 5% greater than the preceding lune[4]. If spread over a large region of the surface of the disk, this asymmetrical disk light distribution would not be apparent in the light curve except through its shift of mid-eclipse times.

The red-component model necessarily produces an oscillatory effect. The oscillation is due to the geometrical appearance of the red component. The amplitude of the oscillation is determined by the relative shapes and sizes of the eclipses and superhumps which, in turn are determined by the distribution of light over the red component. As the red component rotates within the binary frame, the 'centre of light' of the faintest region oscillates about the line of centres with the superhump period. A synthetic light curve based on appropriate eclipse and superhump parameters generates the theoretical O–C diagram shown in Fig. 3 which mimics very well the observed behaviour for OY Car[12]. The variation is caused physically by the changing aspect of the red component and its superhump: if the eclipse minimum ($\phi_0 = 0$) lies before superhump maximum ($\phi_5 = 0$) then the asymmetry of the red component advances the eclipse. When the eclipse lies after the superhump then the asymmetry delays the eclipse.

The observed O–C behaviour of Z Cha[4] does not follow the clean positive/negative oscillation seen for OY Car as the superhump passes through eclipse, but rather a positive shift only. No mechanism is apparent within any proposed model which behaves in this fashion. However, complex structure in both the superspot and disk will distort the behaviour shown in Fig. 3, and low superhump luminosity will reduce its amplitude.

In principle, the structure of the superspot region can be probed using the properties of secondary eclipses. Within the present data no secondary eclipse is apparent. This lack of evidence is not, however, inconsistent with a red-component origin for superhump light. In Z Cha the eclipsed area of the

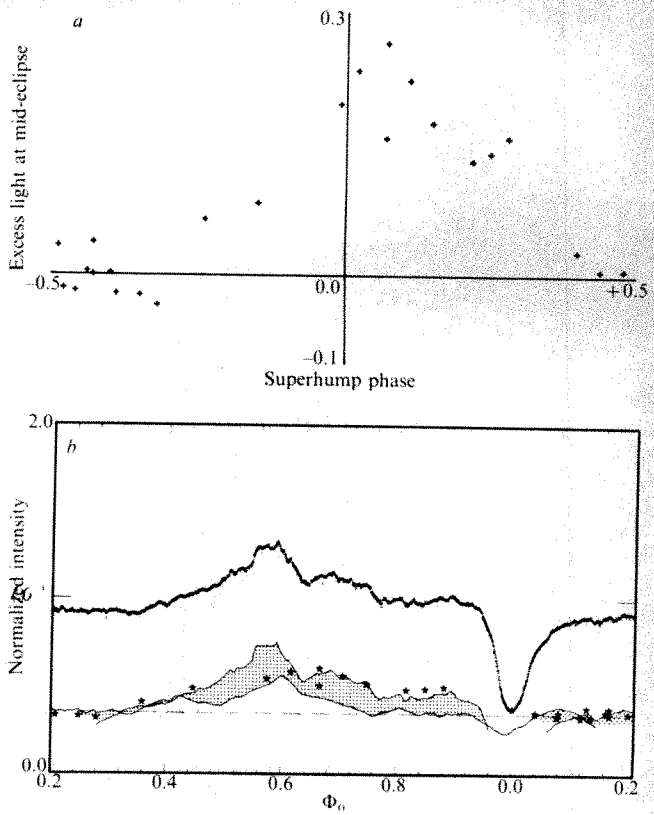

Fig. 2 *a*, The excess light at mid-eclipse in Z Cha as a function of superhump phase. At $\phi_s = 0$ this is typically 25% of the background. The additional light is accounted for by the superhumps, as can be seen in *b* where the points in *a* are replotted under a single cycle of the light curve. The dashed line shows the behaviour of eclipsed superhumps, whereas the shaded region indicates the behaviour of uneclipsed superhumps. The shaded area shows the region enveloped by a bright superhump (early outburst) and a faint superhump (late outburst) in which the eclipse minima will lie, in the case of uneclipsed superhumps. Variations in superhump structure lead to some scatter of the points. Clearly the data show that superhumps are not eclipsed at mid-eclipse.

red component is at most 22% (see Fig. 1). If the superspot is concentrated towards the equatorial belt then the depth of the secondary eclipse is as small as 0.06% of the total light for the case of no temperature change in the eclipsed polar region. Even if the superspot is uniformly distributed over one hemisphere the eclipse light is at most 9% of the total light for bright superhumps, and 5% for more typical cases. Similar constraints apply to OY Car. The present superhump light curves show intrinsic variations (due to superspot structure) at levels comparable to the maximum possible secondary eclipse depth. Such eclipses are therefore not readily visible without more data at times of conjunction of superhump maximum with binary phase = 0.5 to reduce the noise.

In both Z Cha and OY Car the red-component mass is estimated[14] as 0.1–0.2 $M_\odot$ (ref. 14). Such main sequence masses imply quiescent temperatures of ≈4,000 K. Initially the superhump luminosity is ≥90 times brighter than the quiescent luminosity of the red component. With a red-component origin the superhump must then be emitted from a region at a blackbody temperature of at least 12,000 K and probably, with confinement to the equatorial region, superspot temperatures are ≥ 15,000 K. Such a characteristic temperature for the superspot region is in agreement with the colour temperature deduced from UBV fluxes when the superhump is present in both OY Car[12] and the non-eclipsing system VW Hydri[15].

These temperatures are consistent with predicted responses to dynamical, ionization driven overflow instabilities[16,17]. As a result of such instabilities, upwelling of material continues until the ionization zones are brought, by adiabatic expansion, to the

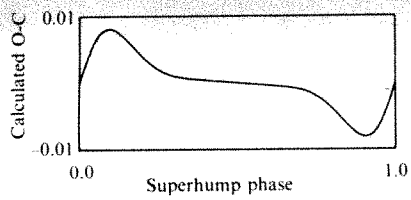

Fig. 3 Model O–C diagram: as the superhump passes through the eclipse, its light alternately shifts the time of minimum to positive, and then negative, phase. The shape and amplitude fit well the observed[12] results for OY Car.

surface. Typical surface temperatures are then 12,000–16,000 K. In normal outbursts these changes will be confined to a region local to the lagrangian point, with typical dimensions of less than a few scale heights ($\leq 0.03R$ in the region of L_1). However, if non-synchronism spreads the instability along the equatorial belt, a significant fraction of the stellar surface can be affected. The streamlines due to non-synchronous rotation will depend on latitude[18], and lead to further stretching of the superspot region along the longitudinal direction. Azimuthal spatial changes in brightness along the equatorial belt would explain the underlying variation in superhump light. The large opacity changes at the expected superhump temperature $>15{,}000$ K may explain the persistent superhump structure on shorter time scales.

The simplest interpretation of the eclipse observations, which has the attraction of being a simple physical structure, is a luminous rotating active region on the equator of the red component. Asynchronous rotation leads to the small period difference between the superhump feature and the binary orbit. Asynchronism may have been driven by the past history of mass and angular momentum exchange (and loss), and gravitational radiation[19]. We stress the close similarity between the marching behaviour of superhumps and the migrating wave in the light curve of RS CVn stars[20], and the geometrical similarity in their suggested structure[21].

The origin of the superspot region is consistent with dynamical instability of the red component at L_1. This powers the superoutburst as fresh unstable material is carried through the L_1 region by slippage of the red component relative to the orbital frame. It remains to be demonstrated that such instabilities will induce disturbances in regions of high latitude. However, pressure gradients will be created over the sub-photospheric equipotential surfaces and may be sufficient to account for the total superhump luminosity by spreading the disturbance to high enough latitudes.

We thank B. Warner, W. Krzeminski, N. Vogt and others for persistent observations of these systems and K. Horne and J. Pringle for discussions.

No IR burst during a type I X-ray burst from the rapid burster (MXB1730−335)

K. Kawara, A. R. Hyland & R. J. Wainscoat

Mount Stromlo and Siding Spring Observatories, Research School of Physical Sciences, Australian National University, Private Bag, Woden Post Office, ACT 2606, Australia

The rapid X-ray burster, MXB1730−335, discovered by Lewin *et al.*[1] and identified[2] with the compact globular cluster Liller 1, produces thousands of X-ray bursts a day when in an active phase. The X-ray bursts have thermal spectra and can be classified into two types by their spectral evolution during burst decay (see ref. 3 and refs therein). Type I bursts normally occur at intervals of hours or days, their spectra soften during decay and their behaviour can be accounted for well by a thermonuclear flash in accreted material on a neutron star. Type I bursts are produced by all other bursters. Type II bursts are unique to the rapid burster, occur at intervals from a few seconds up to 10 min and their spectra do not soften during burst decay. Type II bursts are probably caused by an instability of the accretion flow onto the neutron star. We report here the absence of an IR burst during a type I X-ray burst from MXB1730−335. The upper limit on the IR luminosity during the X-ray burst is 70 times smaller than those of reported IR bursts from this object. This seems to rule out a connection between type I X-ray bursts and the reported IR bursts.

MXB1730−335 became a controversial object when IR bursts were detected. A total of eight IR bursts have apparently been seen by Kulkarni *et al.*[4] (six bursts with a peak flux of ~5 Jy in the H-band) and Jones *et al.*[5] (two bursts with a peak flux of ~7 Jy in the K-band) observing at different times for a total of 8 h. None of these IR variations corresponds with X-ray bursts of the object as the IR bursts they detected were not accompanied by X-ray observations. On the other hand, on nine occasions, an absence of IR bursts during type II bursts was reported by Sato *et al.*[6] and Glass and Carter (reported by Lawrence *et al.*[3]). The upper limits placed on IR bursts by these authors are estimated to be more than one order of magnitude smaller than those of the reported IR bursts. Clearly, then, type II bursts are not normally accompanied by IR bursts. Kulkarni *et al.*[4] suggested that their IR bursts may be associated with type I bursts. During 1980, Lawrence *et al.*[3] conducted 180 h of IR observations and did not detect a single IR burst. The upper limit during the main part of these observations was <0.2 Jy in the K-band, which is more than one order of magnitude smaller than the reported IR bursts. Unfortunately, the rapid burster was in its quiescent state during these IR observations; the Hakucho satellite, which was looking at this source, detected no X-ray bursts[3].

On 5 August 1983, the X-ray satellite Tenma detected type I bursts almost every 72 min, showing that the rapid burster was in an active phase. On 20 August, type II burst activity was present, and the burster terminated its activity on 31 August[7].

We undertook IR observations on 17 August 1983 using K-band (2.2 μm) photometry on the 1.9-m telescope of Mount Stromlo Observatory. Sky chopping was used in an east–west direction with a beam throw of 96 arc s at 20 Hz. The diameter of the beam was 30 arc s. The time constant on the lock-in amplifier was set at 0.3 s. No IR burst was detected during the observation time of 90 min between 10 h 54 min and 12 h 23 min (UT) on 17 August 1983. During this period, a typical type I burst was detected by Tenma. This burst began at 12 h 13 min 31 s (UT), peaked 8 s after the onset and faded completely into the noise ~80 s after the peak. The peak bolometric X-ray flux was 8×10^{-9} erg s^{-1} cm^{-2}, assuming a black-body spectrum (H. Kunieda *et al.*, personal communication). Figure 1 shows the IR raw data recorded on the strip chart at the time corres-

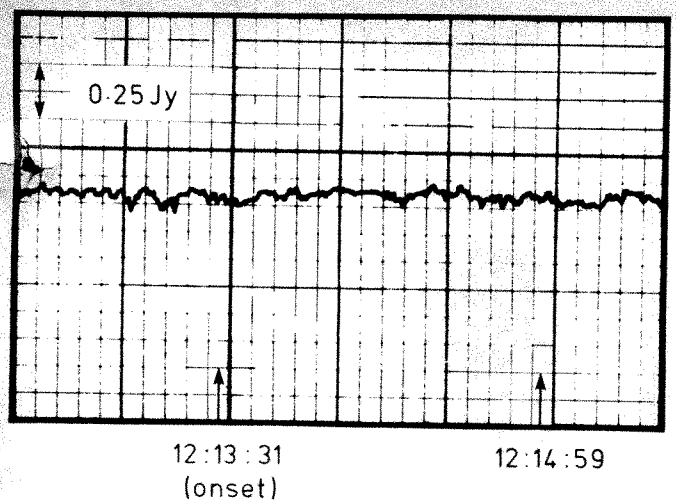

Fig. 1 IR raw data at the K-band corresponding to the time of the X-ray burst, which began at 12 h 13 min 31 s and faded completely into the noise around 12 h 14 min 59 s. The steady level corresponds to the flux from the globular cluster, which has a magnitude of $K = 5.56$ (3.76 Jy) in the 30 arc s aperture.

ponding to the X-ray burst. The steady level corresponds to the flux from the globular cluster. We obtained $K = 5.56$ for the magnitude of the cluster within the 30 arc s aperture, which is consistent with the relation between K-magnitude and aperture size reported by Kleinman *et al.*[8].

The upper limits on variability can be set by using the maximum fluctuations during the observation (times given as UT): $\Delta K < 0.10$ Jy 12 h 13 min 31 s–12 h 14 min 59 s (during the X-ray burst); $\Delta K < 0.25$ Jy 11 h 32 min–12 h 24 min; $\Delta K < 0.4$ Jy 10 h 54 min–11 h 32 min. where 1 Jy corresponds approximately to $K = 7$. Note that the large upper limit of 0.4 Jy in the early part of the observation was probably due to atmospheric conditions and not to luminosity variation of the source.

The upper limit of 0.1 Jy during the type I burst is 70 times smaller than those of reported IR bursts from MXB1730−335. It is unlikely that our time constant of 0.3 s is too long for the detection of IR bursts. Note that Kulkarni *et al.*[4] detected bursts using a time constant of 0.6 s at the H-band as did Jones *et al.*[5] with a time constant of 0.3 s at the K-band.

Our negative result seems to rule out the suggestion by Kulkarni *et al.*[4] that their IR bursts are connected with type I bursts. It is useful to compare our observation with those of other bursters. Coincident X-ray and optical bursts were detected from three type I burst sources, namely 4U/MXB1735−44 (refs 9, 10), MXB1837−05 (ref. 11), and 4U/MXB1636−53 (refs 12, 13). Ten simultaneous X-ray and optical bursts have been observed from 4U/MXB1636−53 by Pedersen *et al.*[12] and Lawrence *et al.*[13] who found that the optical bursts were delayed by a few seconds relative to the X-ray bursts and that the optical burst flux is too large to explain the optical emission as the tail of the black-body X-ray spectrum. It has been suggested[12] that the matter in the vicinity of the X-ray burster absorbs some fractions of the X rays, is heated to $T \sim 50{,}000$ K and re-emits the absorbed energy at optical wavelengths.

The 2.2-μm burst flux which accompanies a type I burst from the rapid burster can be estimated on the assumption that type I bursts from the rapid burster are caused by the same physical process as that suggested for 4U/MXB1636−53; the ratio of the optical peak flux at 3,350–5,250 Å to the bolometric X-ray peak flux is 10^{-3}, after correcting for an interstellar extinction of $A_v = 2.5$ (ref. 11) and assuming that the material heated by the X rays emits a black-body spectrum with $T = 50{,}000$ K at optical and IR wavelengths[13]. The bolometric X-ray burst peak flux of 8×10^{-9} erg s^{-1} cm^{-2} measured by Tenma predicts an apparent 2.2-μm peak flux of 3×10^{-14} erg s^{-1} μm^{-1} cm^{-2} corresponding to 5×10^{-5} Jy assuming an interstellar extinction of $A_K = 1.1$ (ref. 8). This is three orders of magnitude smaller than our upper limit of 0.1 Jy during the type I burst. Hence, if a fraction of type I bursts are accompanied by the reported IR bursts, the mechanism should be quite different from that suggested to explain the well known optical bursts of normal bursters. We note that Lewin *et al.*[14] have also reported the absence of an IR burst during a type I X-ray burst from Ser X-1.

Jones *et al.*[5] pointed out that neither type I nor type II bursts fit the reported IR bursts, whose pattern of occurrence differs from those of X-ray bursts. We conclude that type I bursts do not seem to be accompanied by the reported IR bursts. However, we cannot rule out the possibility that a fraction of type I bursts may be accompanied by the reported IR bursts, as we have only observed one type I burst which shows no IR counterpart.

We thank Dr H. Kunieda and his collaborators from Nagoya University and the Institute of Space and Astronautical Science for providing X-ray data before publication and for collaboration. We also thank Professor H. Okuda for useful suggestions and correspondence.

First optical detection of atomic deuterium in the upper atmosphere from Spacelab 1

J. L. Bertaux*, F. Goutail*, E. Dimarellis*, G. Kockarts† & E. Van Ransbeeck†

*Service d'Aéronomie du CNRS, BP 3, F-91370 Verrières-le-Buisson, France
† Institut d'Aéronomie Spatiale, 3 Avenue Circulaire, B-1180 Bruxelles, Belgium

Measurements of the deuterium-to-hydrogen ratios (D/H) in the fields of meteorology[1,2], tropospheric[3,4] and stratospheric chemistry[5,6], planetology[7,8] and cosmogony[8,9] have previously been performed on molecules in which one hydrogen atom is replaced by one deuterium atom. We report here the first detection of isolated deuterium atoms in the Earth's upper atmosphere through their resonantly scattered Lyman-α emission. An atmospheric deuterium emission of 330 R (1 R = 10^6 photons cm^{-2} s^{-1}) is observed for a tangent altitude of 110 km during Spacelab 1 mission launched on 28 November 1983. The (D/H) ratio of 3×10^{-4} is slightly enriched over the seawater value of 1.6×10^{-4}.

In the terrestrial upper atmosphere, hydrogen atoms are illuminated by the intense solar Lyα line at the resonance wavelength of 121.566 nm in the far UV. The solar Lyα is so wide that it can also illuminate deuterium atoms at the resonance wavelength of 121.533 nm. Through resonant scattering, hydrogen and deuterium can re-emit their Lyα line. Although hydrogen Lyα emission has been observed many times from space, deuterium Lyα has not been detected for two reasons. First, the (D/H) ratio in seawater is only 1.6×10^{-4}. Second, the spectral distance between the two Lyα lines is quite small.

However, the resonance lines of both isotopes are well separated, as their spectral distance of 0.033 nm is much larger than their thermal width of ~0.002 nm. Consequently, the spectral

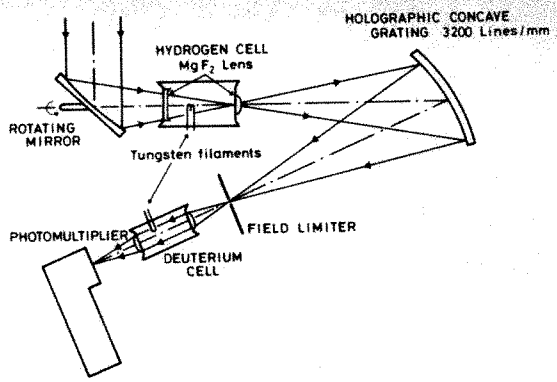

Fig. 1 Optical diagram of experiment 1ES017. The mass of the instrument is 12.5 kg. The dimensions are 685 × 300 × 320 mm and the average power required is 30 W.

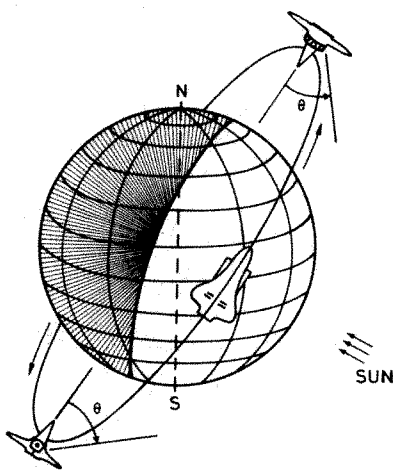

Fig. 2 Geometrical configuration for bright limb observations from an altitude of 250 km. The orbit altitude sketch is greatly exaggerated in respect to the Earth's radius.

resolution needed to distinguish them would have meant using a prohibitively large and heavy classical spectrometer on this first Spacelab mission. We have, therefore, designed and built a lightweight spectrophotometer (Fig. 1) equipped with molecular hydrogen and deuterium absorption cells to suppress selectively one or two of the natural emissions of both isotopes H and D recorded by the instrument. Atmospheric light is collected with a small parabolic off-axis mirror, rotating around one axis to provide a vertical scan of the emission around the limb. The light goes through the hydrogen cell, which is transparent to Lyα when it is not activated, and enters a spectrometer with a single concave holographic grating. A hole at the exit defines both the 2.5° circular field of view of the instrument and a spectral bandwidth of ~4.5 nm centred at Lyα. Thus, the strong atmospheric emission line of atomic oxygen at 130.4 nm is eliminated. The light is then focused on the photomultiplier window through the deuterium cell equipped with MgF_2 lenses. Photons are counted in two counters, sequentially opened in phase with a 5-Hz modulation of the deuterium cell: one counter C_1 is devoted to photons when the deuterium cell is off, the other counter C_2 is devoted to photons when the deuterium cell is activated, that is, when molecular deuterium is dissociated into atoms in the cell.

Fortunately, the atomic hydrogen Lyα emission is saturated, when looking towards the limb, because of the large H column density in the line-of-sight, whereas the optically thin emission I_D of D atoms is proportional to the D column density. As a result, the intensity ratio I_D/I_H is much larger than the (D/H) ratio.

The geometry of observations is illustrated in Fig. 2. The limb is observed from an altitude of 250 km at right angles to the

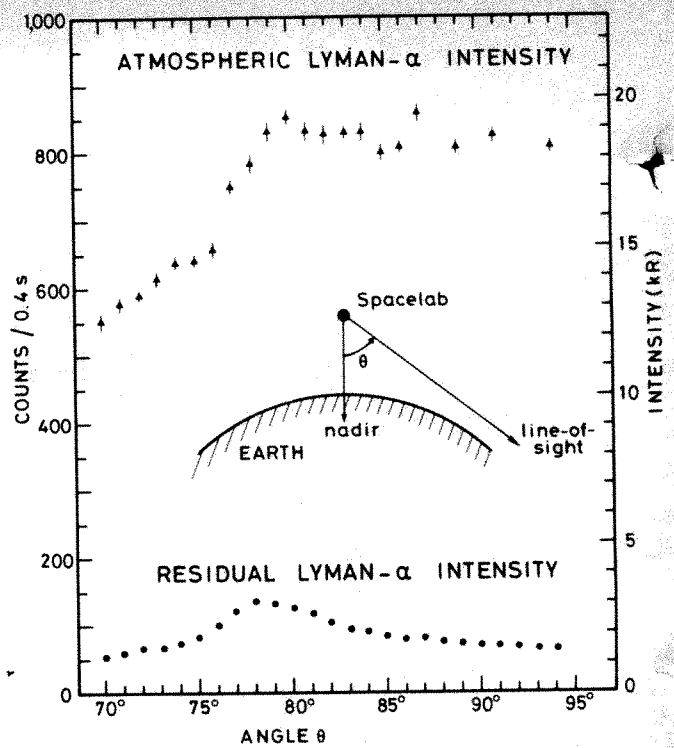

Fig. 3 Measured atmospheric Lyα intensity is shown in the upper part. The residual Lyα intensity indicated in the lower part corresponds to the intensity which is not absorbed when the hydrogen cell is turned on. The left-hand ordinate corresponds to the photomultiplier count rate which is converted into kR in the right-hand scale. The geometrical significance of the observational angle θ is shown in the centre.

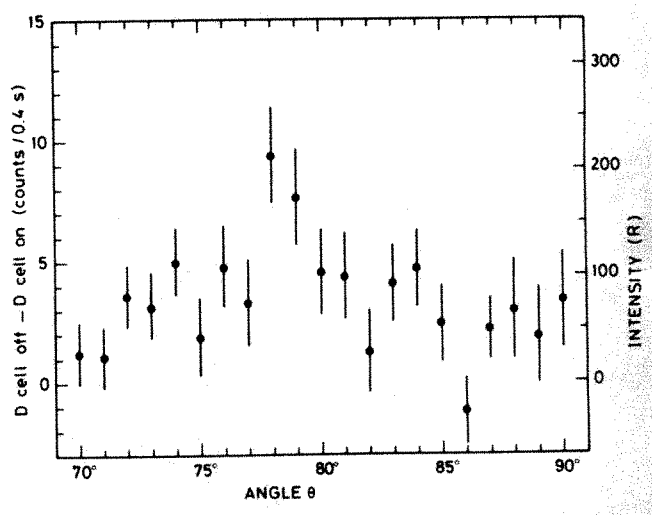

Fig. 4 Atmospheric deuterium Lyα intensity absorbed by the activated deuterium cell. During these measurements the hydrogen cell is permanently on whereas the deuterium cell is alternatively switched on and off. The measured points represent an average of 74 angle scans. Angle θ has the same significance as in Fig. 3.

orbital plane, in order to cancel the Doppler shift associated with the 8 km s^{-1} space shuttle velocity. Otherwise, the absorption cells would have had little or no effect on the atmospheric H and D emissions.

The measured intensity, which essentially results from H Lyα emission, is displayed in the upper part of Fig. 3 as a function of the angle θ with the local vertical. When approaching the limb from below, the H Lyα increases up to the point where the line-of-sight passes above 110 km altitude, corresponding to $\theta = 78°$. Above this height, absorption of Lyα emission by atmospheric molecular oxygen becomes negligible and the Lyα intensity reaches 20 kR.

When a tungsten ribbon is heated electrically in the H_2 cell, an optical thickness $\tau_H \cong 600$ of atomic H is created inside the cell, which absorbs a large fraction (80–90%) of the total signal. The H_2 cell acts as a 'negative' filter and lets through every photon with a wavelength lying outside the absorption profile, which has an equivalent width of 0.006 nm. The transmitted signal is recorded by counter C_1 and shown at the bottom of Fig. 3. It contains mainly H Lyα photons from the linewings, which extend slightly outside the negative filter because of saturation effects.

A small contribution of atmospheric deuterium Lyα emission can then be identified by using the deuterium cell, which creates an optical thickness $\tau_D \cong 1.5$, representing a negative filter selective for D Lyα emission. For $\tau_D = 1.5$, it can be shown that ~60% of the deuterium intensity I_D is absorbed in the cell, and the difference between the two counters $C_1 - C_2$ represents a measurement of $0.6 I_D$. This absorbed intensity is plotted both in counts per 0.4 s and in Rayleighs in Fig. 4.

Seventy-four scans around the limb were averaged and binned in steps of $\Delta\theta = 1°$ to obtain the curve in Fig. 4, representing ~100 min of measurements spread over three orbits and a large range of latitudes. The size of the error bar attached to $C_1 - C_2$ is 2.5 times the error bar attached to counts C_1, which is $(C_1/n)^{1/2}$. Without measurable deuterium emission I_D, the points would be equally positive or negative, which is not the case. Except for one value at $\theta = 86°$, all points are positive, which means that atmospheric deuterium Lyα emission has been unambiguously detected.

A narrow maximum of deuterium emission is found around $\theta = 78°$, at an altitude of ~110 km. This limb brightening effect is expected from the optically thin deuterium emission, when the line-of-sight passes just above the Lyα limb created by atmospheric O_2 absorption. As the field of view of the instrument is 2.5°, it means that the observable deuterium layer is even smaller than what is shown in Fig. 4. However, we can produce a preliminary estimate of the deuterium quantity corresponding to our observations. Because the emitted deuterium Lyα intensity I_D is 330 R, the column number density N_D and the intensity I_D are linked by:

$$I_D(\mathrm{R}) = 10^{-6}\sigma F_s N_D = 10^{-6}\, g\, N_D$$

where F_s is the solar flux[10] of 2.8×10^{12} photons cm^{-2} s^{-1} nm^{-1}. Because the integrated cross-section of D atoms is $\sigma = 5.43 \times 10^{-16}$ cm^2 nm, the excitation rate of D atoms by solar photons is $g = \sigma F_s = 1.52 \times 10^{-3}$ s^{-1}, and these photons are scattered isotropically.

For $I_D = 330$ R, $N_D = 2.2 \times 10^{11}$ atoms cm^{-2} along the line-of-sight tangent at 110-km altitude. We have compared this integrated density to a vertical distribution model depending mainly on one parameter, the eddy diffusion coefficient K, which indicates roughly the altitude of the homopause level, where the atmosphere goes from a well mixed regime to one in which all gases are distributed according to their own scale height and mass. It has been shown[11] that the (D/H) ratio is sensitive to this value of K and also to the exospheric temperature T. Our value of $N_D = 2.2 \times 10^{11}$ atoms cm^{-2} corresponds to a model with a thermopause temperature of 900 K in which the number density is 2.5×10^3 cm^{-3} at 110 km of altitude, and the (D/H) ratio is of the order of 3×10^{-4}. This modest enrichment by a factor of 2 corresponds to a height-independent eddy diffusion coefficient of 1.3×10^6 cm^2 s^{-1}.

Our deuterium observations were hampered during this Spacelab mission by two problems. First, the sensitivity of our first flight model was a factor of 4 below its nominal value, while a second unit unfortunately achieved nominal sensitivity too late to be accommodated in the Spacelab payload. Second, the orbit, because of date and time of launch, soon shifted towards a position near the terminator, where excitation of deuterium atoms by solar Lyα photons is decreased by a larger O_2 column density. As a result, we could observe deuterium emission only during the first 24 h, although the mission lasted for 10 days. A second mission could help to establish a variation of the homopause level with latitude, a major atmospheric objective.

Nevertheless, we have demonstrated that the natural Lyα emission of deuterium atoms can be used to evaluate their number density in the Earth's atmosphere by a remote-sensing technique.

Finally, this remote-sensing technique could be used with the Space Telescope or space probes for the other planets, in particular for Venus and Mars, where the (D/H) ratio is unknown. For Venus, a (D/H) ratio of 1.6×10^{-2} was found[7] in a cloud droplet sucked by a neutral mass spectrometer on board the large probe of Pioneer Venus mission. Such a high value can be explained only by a fantastic differential escape of both isotopes[12,13], the heavier D atoms being left behind in the atmosphere of Venus. The quantity of water at the origin of Venus was at least 100 times larger[7] than it is now.

Such an important clue about the history of water on Venus deserves further investigation. We have demonstrated the feasibility of the deuterium Lyα detection technique. It can now be applied to detailed terrestrial and planetary studies.

We acknowledge the financial support of the French Centre National d'Etudes Spatiales (CNES) and of the Belgian Administration de la Recherche Scientifique (Ministry of National Education). The technical support of ESA and NASA during integration and flight was greatly appreciated.

Crustal evolution in north-east and east Africa from model Nd ages

N. B. W. Harris, C. J. Hawkesworth & A. C. Ries

Department of Earth Sciences, The Open University, Milton Keynes MK7 6AA, UK

The relationships between the various crustal provinces that comprise north-east and east Africa are far from clear and reflect diverse tectonic and magmatic processes which took place during the Proterozoic. Here we present the results of an Nd isotope study on the major rock units of the Pan-African (1,100–500 Myr BP) terrane. Charnockites from Jabel Uweinat, a basement inlier at the junction of Egypt, Libya and the Sudan, yield middle Archaean model Nd ages, whilst model ages of <1,200 Myr have been obtained in a belt from the Eastern Desert of Egypt to north-west Kenya. This, therefore, represents a westward extension of the juvenile Pan-African crust of the Arabian Shield (Fig. 1). The shield itself is characterized by comparatively rapid crustal growth[1], probably in an accreting island arc environment[2]. Between the two areas, there is a marginal zone of Pan-African rocks with relatively low $\varepsilon_{Nd}(T)$ values (see Table 1) due to increased contributions from the pre-Pan African crust. Overall, the Pan-African rocks from north-east and east Africa and those from the Damara of Namibia[3] exhibit a wide range of $\varepsilon_{Nd}(T)$ from +7.5 to −18.0 which reflects regional changes in tectonic style and is not readily reconciled with simple models for the evolution of average continental crust.

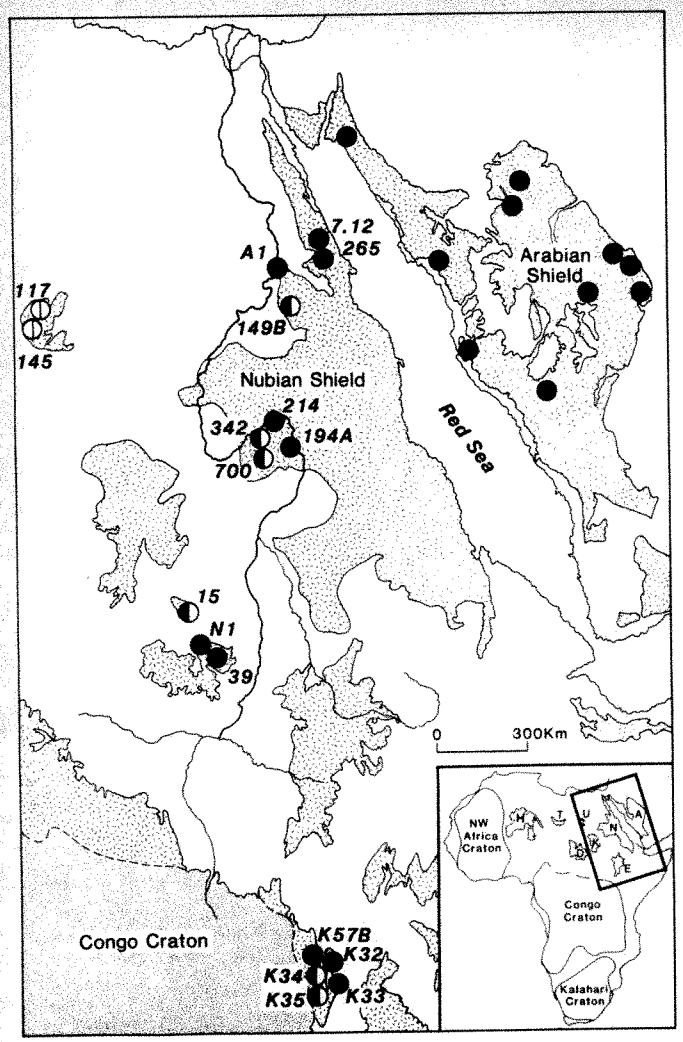

Fig. 1 Sample location map showing extent of basement outcrop and distribution of Nd model ages in north-east and east Africa and Arabia. ●, 800–1,300 Myr; ◐, 1,600–1,900 Myr; ⊙, 3,000–3,200 Myr. Inset shows the location of the study area relative to African cratons of Archaean age, and basement inliers at Hoggar (H), Tibesti (T), Jabel Uweinat (U), Darfur (D), Kordofan (K) and western Ethiopia (E); also shown are Nubian (N) and Arabian (A) shields.

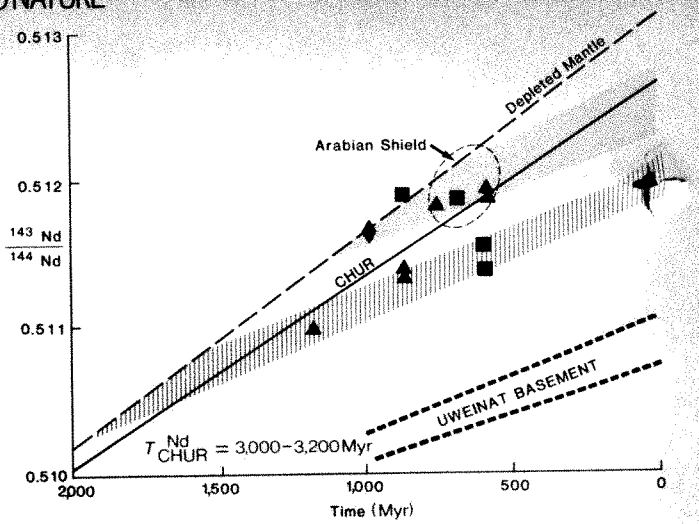

Fig. 2 Variations in initial $^{143}Nd/^{144}Nd$ ratios in samples from north-east and east Africa. The stippled region encloses the evolution lines for samples 265, 7.12, A1, 194A, 214, N1, 39, K32, K33 and K57B. The hatched region encloses the evolution lines for samples 342, 700, 15, 149B, K34 and K35. Evolution paths truncated by inferred light REE-depleted mantle[6]. ■, Granitic and meta-igneous samples; ▲, metasediments; ◆, amphibolites. Field of Arabian data taken from ref. 1.

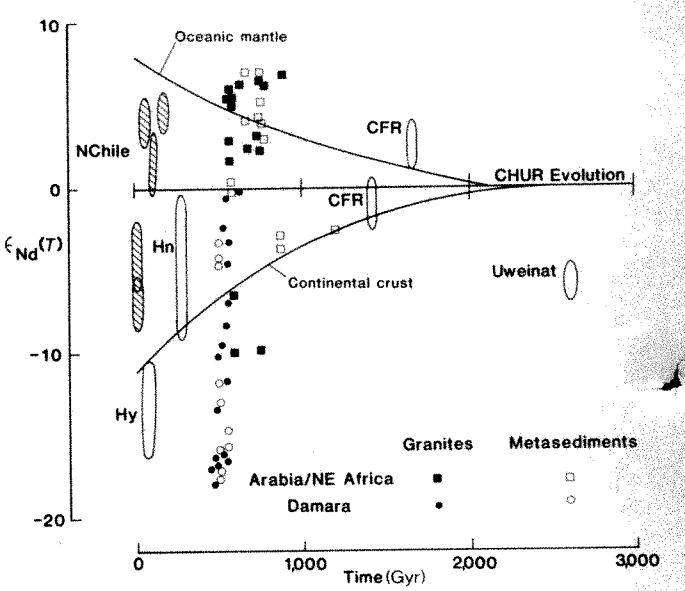

Fig. 3 Mixing model curves for evolution of oceanic mantle and continental crust assuming that the last two orogenies contributed to continental crust[27]. Pan-African data are taken from north-east Africa, Arabia[1] and Damara[3,30]. Also shown are data from northern Chile[29,31], Himalayas (Hy)[27], the Hercynian of south-west Europe (Hn)[27,28] and the Columbia Front Range (CFR)[6].

The Karkur Murr charnockites from Jabel Uweinat (Fig. 1) form the oldest known basement in north-east Africa[4,5] and two samples have model Nd ages, relative to depleted mantle[6], of 3,000 and 3,200 Myr (Fig. 2, Table 1). This confirms their Archaean age, while their low $\varepsilon_{Nd}(T)$ and high $\varepsilon_{Sr}(T)$ values indicate that the event dated at 2,617 ± 21 Myr by Rb/Sr whole rock analyses[5] involved considerable crustal reworking. Figure 2 also illustrates that none of the other samples from this study has a uniquely Archaean source. Most samples from Egypt and the Sudan have Nd model ages between 750 and 1,150 Myr. They are therefore isotopically indistinguishable from the juvenile Pan-African crust of the Arabian Shield[1,7]. The amphibolite from the Marich area (K57B) of north-west Kenya[8,9] and the foliated granodiorite from the Abu Harik complex (194A) of the Bayuda Desert of the western Nubian Shield[10] lie just above the evolution path for average depleted mantle, as do some of the Pan-African rocks from Arabia[1,7]. The metasediment (265) and the foliated granite (7.12) from the Hafafit region of Egypt represent the highest grade of metamorphism in the Eastern Desert[11] and lie well within this age group, indicating that, despite their strong deformation, they are Pan-African in age and were derived from juvenile crust. The Aswan granite (A1) has high initial $\varepsilon_{Nd}(T)$ (+2.3) and low initial $\varepsilon_{Sr}(T)$ (−8.5), values similar to those reported from other younger granites in the Eastern Desert[12] and to many recent mantle-derived rocks. However, this lack of evidence for at least a significant contribution from older crustal material is apparently at variance with published radiogenic lead isotope results[13,14]. This may simply reflect differences between the samples analysed; other Rb–Sr studies[15] have reported initial $\varepsilon_{Sr}(T)$ as high as +70, implying that the Aswan granite was isotopically heterogeneous at the time of emplacement. Alternatively, radiogenic lead could have been introduced by subduction processes, as has been recently demonstrated in the Lesser Antilles[16] where samples with $\varepsilon_{Nd}(T) = +2$ have $^{207}Pb/^{204}Pb =$

$\varepsilon_{Nd}(T)$ is the deviation from the value expected in a chondritic reservoir (CHUR) at time T, and is defined as $\varepsilon_{Nd}(T) = 10^4\left[\frac{^{143}Nd/^{144}Nd_{rock}(T)}{^{143}Nd/^{144}Nd_{CHUR}(T)} - 1\right]$ where $^{143}Nd/^{144}Nd_{CHUR}(T) = 0.51264 - 0.1967[(\exp \lambda_{Sm} T) - 1]$. T_{DM} calculated using values from ref. 6.
* Assuming age of 750 Myr. † A.C.R., unpublished data. ‡ Isochron initial $^{87}Sr/^{86}Sr$ ratio.

15.73. Farther south, the quartzite from the Abu Hamed series of the Bayuda Desert[10] (214), and the Rashad granite (N1) and the Abbasiya granodiorite (39) from the Nuba Mountains of southern Kordofan, central Sudan[17] are derived from the source regions of Pan-African age.

The third group of results provides Nd model ages between 1,500 and 2,000 Myr. Model ages in this range were not observed in a recent Nd isotopic study of the Arabian Shield[1] (Fig. 1). In general, such isotopic characteristics may be derived either from a source region of this age or from mixed sources including, presumably, both Archaean and Pan-African material. In the case of the Marich granite (K34, K35), which is exposed 20 km east of the margin of the Congo Craton in north-west Kenya[8,9], its high $\varepsilon_{Sr}(T)$ and low $\varepsilon_{Nd}(T)$ values confirm that it was derived from pre-existing continental crust, and its model age implies that the source included a pre-Pan-African component. The variation in model age between the two samples indicates that isotopic homogeneity was not reached during anatexis, consistent with the scatter of the Rb/Sr whole rock analyses (mean sum of weighted deviates = 51; A.C.R., unpublished data). The Sekerr metasediments (K32, K33) into which the Marich granite is intruded have model ages of 1,150–1,100 Myr, implying that little, if any, of the sediment was derived from the Archaean craton to the west. The muscovite granite (15) from the El Obeid area of Kordofan Province, Central Sudan, also has a low present day $^{143}Nd/^{144}Nd$ ratio relative to that of granite of known Pan-African age, but its model age cannot be calculated since its evolution path closely parallels CHUR. Its flat rare earth element (REE) profile is typical of peraluminous granites and indicates an increase in Sm/Nd during melting. In the simplest model, if it is assumed that melting occurred during the Pan-African from a single source with a Sm/Nd ratio similar to that of average crust, the model Nd age of the source would be at least 2,000 Myr. Thus both the El Obeid and the Marich peraluminous granites contain significant contributions from the pre-Pan-African crust. Similarly, some of the source regions for the Rahaba metasediments in the Bayuda Desert[10] (342, 700), initially mapped as grey gneisses and identified as the oldest Pan-African units in their area[18], and for the amphibolite facies metapelites in southern Egypt[19] (149B) must also predate the major Pan-African crust-forming episodes. These data support the existence of early Proterozoic crust, but argue against the presence of Archaean basement, in the western Nubian Shield and in the Kordofan inlier[20,21].

Nd-isotope studies have therefore identified important differences in the character of the Pan-African terrane across Arabia and north-east Africa. The samples analysed from Arabia all have positive $\varepsilon_{Nd}(T)$ values and none of them is likely to have crustal precursors older than 1,200 Myr (ref. 1) (Figs 1, 2). Similar results were obtained on samples along a belt from southern Egypt to north-west Kenya, but to the north-west there is a shift to lower ε_{Nd} and hence older model Nd ages, culminating in the Archaean ages from Jabel Uweinat. Thus an area of predominantly juvenile Pan-African crust is bounded by one in which rocks apparently formed during the Pan-African event nonetheless have model Nd ages of 1,500–2,000 Myr. However, these rocks are (1) metasediments, and (2) peraluminous granites chosen from areas of higher metamorphic grade as probable crustal melts. There is no evidence of a decrease in $\varepsilon_{Nd}(T)$ in subduction-related magmas (such as A1 and 194A) near the margins of the craton, suggesting that the $\varepsilon_{Nd}(T)$ values of these rocks have not been affected by contamination with upper crustal material. Furthermore, this study has failed to identify any Archaean crust to the east of Jabel Uweinat, and since the Egyptian and Sudanese samples are tightly grouped into two discrete suites, the data suggest that the Archaean basement exposed at Jabel Uweinat was rimmed by younger pre-Pan-African crust of 1,500–2,000 Myr. Two upper intercept U–Pb zircon ages from distinct metasediments in the Eastern Desert—a granite pebble from a conglomerate in Wadi Mobarak (1,960 ± 200 Myr)[22] and an arkosic metasediment from Wadi

Nugrus (1,700 ± 40 Myr)[23]—support such a view. Moreover, in the Hoggar region of north-west Africa a widespread 'Eburnean' event of granulite metamorphism at 2,000 ± 100 Myr has been identified[24]; in the Jabel Uweinat inlier crustal anatexis has been recorded at 1,800 ± 40 Myr (ref. 5); zircons from Phanerozoic sandstones in Tunisia indicate an age of 1,750 ± 100 Myr (ref. 25) and in the Iringa region on the edge of the Mozambique Belt in Tanzania isotopic ages of 1,850 ± 100 Myr are common[26]. Thus it is not unreasonable that crust of this age was sampled by sediments in the Eastern Desert and the Bayuda Desert, and by anatectic melts in central Sudan and north-west Kenya.

The Pan-African event represents a critical stage in the evolution of both large-scale tectonic processes and the continental crust. The volume of stable continental crust has increased, probably at varying rates, since ~4,000 Myr. Since the stabilization of such low Sm/Nd, high Rb/Sr crust is held to be primarily responsible for the high Sm/Nd, low Rb/Sr characteristics of most of the upper mantle, the Nd- and Sr-isotope ratios of the average crust and average upper mantle have also diverged with time[27] (see Fig. 3). Successively younger orogenic episodes, and particularly those over the last 1,000 Myr, should therefore have had more opportunity to remobilize crust which was old enough to have developed distinctive isotope ratios.

Figure 3 summarizes data on granitic rocks from Columbia Front Range[6], the Hercynian of Europe[27,28], the Himalayas[27], and on both extrusives and intrusives from a section across the northern Chilean Andes[29]. Igneous rocks older than 2,000 Myr tend to have initial Nd- and Sr-isotope ratios close to those of the bulk Earth[27] (although Jabel Uweinat offers an interesting exception) while the Phanerozoic examples have variable and often lower $\varepsilon_{Nd}(T)$ values. Thus the young granitoids contain a greater contribution from significantly older crust, either because little old crust survived early in Earth's history and/or younger granites were generated by different processes. Also shown in Fig. 3 are analyses of Pan-African granitoids and metasediments from Arabia[1], north-east Africa and the Damara Belt in Namibia[3,30] with calculated curves for the evolution of average continental crust and upper mantle[27]. Superficially the wide range of $\varepsilon_{Nd}(T)$ in the Pan-African is difficult to reconcile with the curve for the evolution of average crust, but that in part depends on the processes responsible for $\varepsilon_{Nd}(T)$ values in orogenic rocks.

The range of $\varepsilon_{Nd}(T)$ in the Pan-African samples reflects differences in the tectonic regime, and in the age of the pre-existing crust. Areas of significant crustal accretion have ε_{Nd} = +2 to +7, and it requires a marked change in thermal regime, with an increase in metamorphic grade usually associated with crustal thickening, to generate predominantly crustal-derived magmas with low $\varepsilon_{Nd}(T)$ (for example, the Damara[30]). In this case $\varepsilon_{Nd}(T)$ values primarily reflect the age of the pre-existing crust. But crustal thickening is typically a late and comparatively short-lived stage in an orogenic cycle, and thus the low $\varepsilon_{Nd}(T)$ granites are often trivial volumetrically. For example, a detailed section across the northern Chilean Andes[29] has shown that from the start of the present orogenic cycle at ~185 Myr until ~20 Myr the intrusive and extrusive rocks had $\varepsilon_{Nd}(T) = +6$ to 0, and it is only over the past 10–15 Myr, since the development of thick crust, that low $\varepsilon_{Nd}(T)$ rocks have been generated[31] (see also Fig. 3). Similarly, in the Himalayas subduction zone related magmatism associated with the closure of Tethys may have occurred since the Upper Triassic, but the low $\varepsilon_{Nd}(T)$ rocks on Fig. 3 are small-volume, post-collisional crustal melts again formed in response to crustal thickening.

Thus, while crust-forming processes tend to generate magmas with $\varepsilon_{Nd}(T) = +7$ to +2 (as in northern Chile and Arabia, Fig. 3), the Nd-isotope composition of low $\varepsilon_{Nd}(T)$ granites is, like that of sediments, primarily an indication of the age of the local pre-existing crust. As demonstrated here for the Pan-African, the $\varepsilon_{Nd}(T)$ values of magmatic rocks can vary dramatically even in broadly contemporaneous orogenic areas, depending on both the age of the basement and the tectonic environment.

We thank P. Bridges, W. R. Church, R. Greiling, J. Klerkx, D. O'Halloran and J. R. Vail for samples, and R. M. Shackleton and I. G. Gass for their constructive reviews.

Effects of acidification and complexation from radiolytic reactions on leach rates of SYNROC C and nuclear waste glass

Desmond M. Levins

Roger St C. Smart

School of Science, Griffith University, Nathan, Queensland 4111, Australia

Previous work[1] has shown that γ-radiation induced enhancement of leach rates from high-level radioactive waste (HLW) solids can be attributed to radiolytic acidification of the aqueous solution and to radiolytic formation of organic complexing species, for example, $(COOH)_2$, HCOOH. Barkatt *et al.*[1] compared the leach resistance of three HLW glasses and SYNROC D (specifically designed for incorporation of US defence wastes[2]) and found that, at low *p*H and with complexing agents, higher alumina contents in the waste form gave large enhancement of leach rates. Specifically, in acid solution, the elemental leach rates for SYNROC D were increased relative to the glasses by factors between 20 and 1,200. The formulation of SYNROC C, designed by Ringwood[2] for incorporation of reprocessed waste from commercial power reactors, was not tested in these conditions. We report here that SYNROC C is considerably more resistant than the standard HLW glass PNL 76–68 to acid attack and to possible complexation reactions between 90 and 150 °C, despite an alumina content in the formulation that is much higher than that for PNL 76–68. The Al content of SYNROC C is much lower than that of SYNROC D (Table 1) and it is largely present in the hollandite phase after hot pressing. No aluminosilicate phases are formed in SYNROC C and, for this reason, the *p*H dependence is much less marked. These results are significant in assessing the effects of changes induced by the ionizing radiation to which the HLW solid and solution will be exposed during geological isolation.

Table 1 Compositions (wt%) of SYNROC and waste glass PNL 76–68

	SYNROC C (batch 160)	SYNROC D (S21S18)	PNL 76–68
TiO_2	56.0*	21.9	3.0
ZrO_2	11.9*	5.8	1.9
Al_2O_3	5.4*	18.9	—
SiO_2	<0.1*	6.7	38.3*
CaO	13.5*	6.6	2.5*
BaO	5.7*	1.2	0.5*
Fe_2O_3	1.1	23.0	10.3
B_2O_3	—	—	9.1*
SrO	0.7*	0.2	0.5*
Cs_2O	0.7*	0.2	1.2*
Na_2O	—	3.2	12.8
Rare earths and others	5.0	12.3	19.9

* Measured values, otherwise nominal compositions are given.

Ringwood has proposed several different formulations of SYNROC to accommodate various types of high-level nuclear waste[2]. The two formulations that have received most attention are SYNROC C and SYNROC D. Commercial and defence wastes differ in composition and the corresponding SYNROCs also vary considerably in mineralogies and properties[3,4]. The compositions, on an oxide basis, of both SYNROCs and the standard HLW glass PNL 76–68, supplied by the Materials Characterization Center (MCC) at Pacific Northwest Laboratory (PNL)[5], are given in Table 1. SYNROC C can immobilize >20 wt% commercial wastes and has four major phases of perovskite ($CaTiO_3$), hollandite ($Ba(Al, Ti^{3+})_2Ti_6O_{16}$), zirconolite ($CaZrTi_2O_7$) and rutile TiO_2 with some minor metal alloy phases[3]. SYNROC D, however, designed to accommodate up to 65% defence wastes, has major phases of hollandite, zirconolite and perovskite but also an aluminosilicate nepheline ($NaAlSiO_4$) and a spinel titanate phase ($(Fe, Ni, Mn)(Al, Fe)_2O_4$-$(Fe, Ni, Mn)_2TiO_4$)[4]. The last two phases normally comprise about two-thirds of SYNROC D on a volume basis. The high alumina content of SYNROC D arises, not from SYNROC D additives, but from the waste itself.

Barkatt *et al.*[1], in examining the effect of γ-radiolysis on HLW glasses and SYNROC D, reported HNO_3, HCOOH and $(COOH)_2$ at concentrations of 78, 46 and 30 μmol dm^{-3} after 3 days irradiation with a ^{137}Cs source (8.6×10^4 rad h^{-1}). Although it is recognized[1] that a very low *p*H is unlikely to be found in a high-level waste repository (owing to buffering by rock minerals), the local effect of acidification near the waste surface as well as the effect of organic complexing agents in solution may be important. We have tested both effects in a comparison of SYNROC C and PNL 76–68.

The SYNROC C used in our experiments was prepared by the standard oxide-route method[6]. This entailed mixing the precursor oxides or carbonates with a simulated waste solution containing a shortened version of the reference US commercial waste PW-4b[6]. The waste loading was 10 wt% on an oxide basis. After calcination at 1,100 °C in an Ar/3% H_2 atmosphere, 2 wt% Ti powder was added and the blended powder hot-pressed at 1,250 °C for 3 h. The test specimens were 10 mm diameter by 2-mm thick discs of SYNROC C and PNL 76–68 prepared according to the method recommended by the MCC[5]. The flat faces of these discs were ground to a 240–300 grit finish before leaching.

Table 2 compares the leach rates of SYNROC C and PNL 76–68 in static test conditions (MCC-1) at 90 °C for 7 days. The leachants were *p*H 1.8, 4.2, 7.0 and 9.0 buffer solutions. The results clearly show that, in all test conditions, the leach resistance of SYNROC C is superior to that of borosilicate glass PNL 76–68. Furthermore, the leach rate of SYNROC C is less susceptible than glass to changes in *p*H. The difference in the leach rate of the major SYNROC matrix elements, titanium and zirconium, compared with that of the major borosilicate glass matrix elements, silicon and boron, is particularly striking. Although the leach rate of Ti from SYNROC C increases by a factor of >250 when the *p*H is lowered from 7 to 1.8, it is still 200 times lower than that of silicon from glass. The method of reporting results as a ratio of leach rates at two different *p*H values, used by Barkatt *et al.*[1], tends to obscure such information.

Campbell *et al.*[7] have measured the leach rates of SYNROC D in deionized water in identical test conditions (MCC-1). Table 3 shows that SYNROC C is clearly more resistant to leaching than SYNROC D and PNL 76–68. The differences in leach rates of the two types of SYNROC are clearly indicated in the results for Al, Ca and Sr. Table 3 also indicates that the leach rate of Si from SYNROC D is quite high. These facts support the contention[1,2] that it is the aluminosilicate phase in SYNROC D, known to exhibit a sharp dependence of dissolution on *p*H, that is leachable. Conversely, our results show that the absence of aluminosilicate phases in SYNROC C lead to much enhanced resistance to leaching.

Table 4 compares leach rates of SYNROC C and PNL 76–68 in more extreme conditions. Hydrothermal leaching at 150 °C in Teflon-lined Parr autoclaves was used to simulate conditions that could occur if shorter storage times were used before disposal. We have used an acidic solution of nitric acid (0.16 mol dm^{-3}), formic acid (0.37 mol dm^{-3}) and oxalic acid (0.01 mol dm^{-3}) in the proportions 2:1:1 by volume to test the effect of organic acid complexation as well as acidification (*p*H was adjusted to 1.5 with concentrated ammonia solution). The discs were leached in 10 cm^3 of the acid mixture for 1 day; the leachant was then replaced and leaching continued for a further 5 days. Table 4 shows the leach rate for the first day and the average for the entire 6 days. After leaching of the glass, a gel layer had formed on the Teflon container walls and a sediment settled on the bottom of the container. These solids were

Table 2 Leach rate (g m^{-2} day^{-1}) of borosilicate glass (PNL 76–68) and SYNROC C (batch 160) as a function of *p*H (MCC-1 test conditions at 90 °C for 7 days)

dissolved and their considerable contribution to the leach rate was determined as shown by the numbers in parentheses in Table 4. The results show clearly that in these extreme conditions, SYNROC C has superior leach resistance. When compared with results at *p*H 1.8 (Table 1), it is seen that the leach rates of both glass and SYNROC are enhanced by the combination of lower *p*H, higher temperature and organic acids by a factor generally <10.

The leach rates we have reported are based on relatively short-term tests (7 days) and relatively low surface area/solution volume ratios. They therefore represent a comparison of relative reactivity towards acid attack and organic acid complexation in initial leaching. The long-term effects of, for instance, solution saturation, reprecipitation and recrystallization have not been considered but some comments on Cs, the most leachable radwaste element, are relevant. Table 4 shows that, in acidic hydrothermal conditions, the leach rate of glass and SYNROC C decreases with time. Glass leaches more or less congruently, but caesium is the most leachable element from SYNROC C. The relatively high initial leach rate of caesium from SYNROC occurs because a small amount (<5%) is incorporated not in the hollandite phase but in intergranular films[8]. The high initial rate is caused by the leaching of this loosely bound caesium. Preferential leaching during the first few days depletes the near-surface region of the intergranular regions and as the thickness of the leached layer increases, so the rate of dissolution decreases. Solomah and Zumwalt[9] found that at 25 °C the caesium leach rate fell from 0.07 $g\,m^{-2}\,day^{-1}$ after 3 days to 0.0004 $g\,m^{-2}\,day^{-1}$ after 100 days. Similarly, Reeve *et al.*[6] found that the leach rate at 100 °C fell from 0.4 $g\,m^{-2}\,day^{-1}$ after 1 day to 0.002 $g\,m^{-2}\,day^{-1}$ after 70 days. The caesium leach rate can be improved further[6] if the SYNROC precursor is prepared by hydrolysis of titanium and zirconium alkoxides following the SANDIA method[10]. The leach rate of Cs from glass is constant when the leachant replacement rate is high[6]. In static conditions the average leach rate decreases by a factor of about three over the first 100 days[11] but, like SYNROC C, the instantaneous leach rate of Cs after 6 months is not measurable[6,11].

It is clear, then, that acidification and complexation effects resulting from γ-radiolytic reactions may be important in assessing different HLW forms. The incorporation of alumina as an aluminosilicate in crystalline materials or as a network-former in glassy materials could result in a large increase in leachability in irradiated aqueous media. SYNROC C, in which the alumina is incorporated into the hollandite phase, shows a much smaller increase than PNL 76–68 or SYNROC D in leachability in conditions expected in the first phase after disposal.

We thank Ms T. Morley-Buchanan, Mr J. Cooper, Mr F. Jackson and Mr A. Reid for assistance in carrying out the experiments and chemical analyses.

In the British Quaternary, two post-Cromerian interglacials, the Hoxnian and the Ipswichian, are recognized[1]. Evidence of additional interglacials in this interval is widely accepted in the oceanic record of Quaternary events[2], and the possibility that at least one additional interglacial of this age is represented in Britain has been discussed[3–5]. However, in the absence of datable interglacial deposits which are seen to overlie one another, the issue has remained controversial. We describe here deposits at Marsworth, UK (Fig. 1) where there is evidence of two temperate episodes, and of intervening periglacial conditions. Stratigraphical superposition is established beyond any reasonable doubt. The later deposit relates to the temperate woodland stage of the Ipswichian Interglacial. Dating of the earlier temperate material by the $^{230}Th/^{234}U$ disequilibrium method indicates an interglacial episode not previously established in the British Quaternary.

Table 1 Mammal faunas of the Marsworth channels

Upper channel	Elephant (indeterminate)
	Dicerorhinus hemitoechus (Falconer)
	Hippopotamus amphibius Linné
	Megaceros giganteus (Blumenbach)
	Cervus elaphus Linné
	Bison priscus Bojanus
	Arvicola terrestris Linné
	Microtus sp.
Lower channel	*Canis lupus* Linné
	Ursus arctos Linné
	Panthera leo Linné
	Mammuthus primigenius Blumenbach
	Equus ferus Boddaert
	Equus hydruntinus Regalia
	Cervid (indeterminate)
	Bovini (indeterminate)
	Microtus oeconomus (Pallas)

At the base of the succession at A (Fig. 2), a channel up to 35 m wide in the surface of the chalk (lower channel) contains sediments of a shallow stream. The channel-fill includes gravelly sands below, passing up into organic mud. The organic mud is confined to the area indicated in section E–F (Fig. 3), but the gravelly sands have been traced continuously in this section. The organic muds and the gravelly sands are overlain by chalky muds full of small chalk pellets. Lenses of water-laid sand and fine gravel are also present. These largely colluvial deposits, up to 4 m thick, are found within and beyond the lower channel and are overlain by a coarser head of chalk and flint debris. This Coombe Rock, 2–3 m thick and involuted in its upper part, can be traced across the site of the lower channel and widely beyond it.

At B (Fig. 2), a separate channel (upper channel), 8 m wide, was present in the surface of the Coombe Rock, truncating the involutions. It contained finely stratified sandy gravel, and marl. There were several small pond-like depressions containing similar deposits nearby.

The lower channel-fill contains abundant fossil material, including molluscs, ostracods, beetles, vertebrates and pollen and plant macrofossils. Travertine is present in clasts up to 0.8 m long, and bears occasional leaf impressions of temperate woodland species, including *Acer*. It also contains Mollusca of temperate woodland habitats, including *Azeca goodalli*, *Discus rotundatus* and *Clausilia bidentata*. The upper channel contained abundant mammalian bone, but no other fossil material.

In the mud of the lower channel-fill, herbs dominate the pollen and macrofossil flora throughout. Gramineae are best represented in the pollen record, with subsidiary amounts of Cyperaceae and many grassland herbs. The small quantities of tree and shrub pollen consist mainly of *Pinus* with occasional *Picea*, *Abies*, *Betula*, *Quercus*, *Ulmus*, *Alnus*, *Salix*, *Juniperus* and *Ribes*. Aquatic pollen is present (*Potamogeton*, *Hippuris* and *Butomus*) and late in the sequence the spore flora includes *Lycopodium clavatum* and *Selaginella selaginoides*. The Mollusca are predominantly undemanding in their habitat requirements (for example, *Trichia hispida*, *Arianta arbustorum*). In the lower part of the sequence, marsh and aquatic species occur, including *Oxyloma pfeifferi* and *Sphaerium corneum*. In the upper part of the sequence they are replaced by grassland species such as

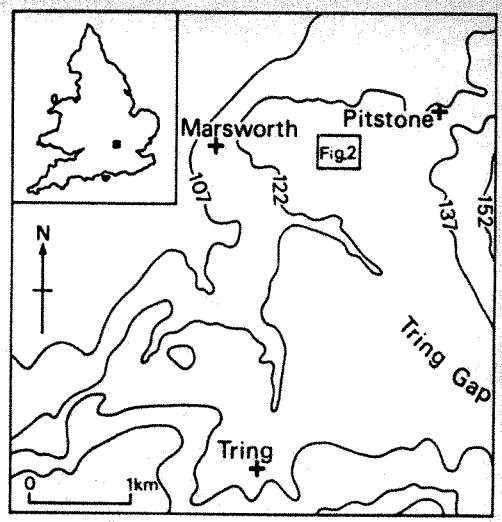

Fig. 1 Map showing the location of Marsworth.

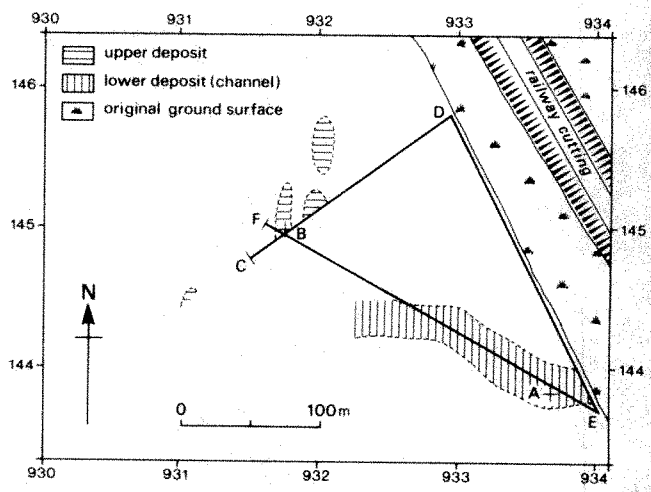

Fig. 2 Pleistocene fossiliferous deposits in Pitstone no. 3 quarry, Marsworth, showing alignment of sections illustrated in Fig. 3. National Grid coordinates are given at the margin (100 km square SP).

Pupilla muscorum, together with many fragments of *A. goodalli* and *C. bidentata*, possibly derived from earlier sediments or soils. The lower part of the sequence yields an ostracod fauna of limited species diversity, dominated by *Prionocypris serrata*, and including *Ilyocypris bradyi*, *Candona neglecta* and *Potamocypris* spp.

Eighty species of Coleoptera are present and suggest a temperate marshy grassland habitat dominated by *Glyceria maxima*, the foodplant of *Donacea semicuprea* and *Notaris acridulus*, which are both common. The abundance of dung beetles suggests that the grassland was grazed, and the small carnivorous beetle *Anotylus gibbulus*, which is also common, is probably associated with the dung of large herbivores. The central and southern European weevil *Stomodes gyrosicollis*, which lives on

various species of clover, is present. Late in the sequence, an increase of the less thermophilic species, including *Pycnoglypta lurida*, *Arpedium brachypterum* and *Olophrum fuscum*, occurs. The mammal fauna (Table 1) is an assemblage recorded at several sites in Britain[6,7]. These *Mammuthus–Equus* faunas are distinguished by a large form of lion, *Panthera leo*, and a small form of wolf, *Canis lupus*. At Marsworth, the fauna includes *Microtus oeconomus* and the extinct equid, *Equus hydruntinus*.

The fossils in the lower channel-fill indicate a shallow spring-fed stream with backwater slacks, in a local context of marshy grassland. The stream was subsequently replaced by *Carex*-dominated swampy depressions, and these were finally infilled by colluvial debris. The regional vegetation was predominantly grassland throughout the period of record. A climate similar to that of northern England today is represented, with indications in the travertine of earlier warmer conditions, and in the deposits themselves and the fossils contained therein, of slight cooling during sedimentation.

Travertine from the lower channel was dated by the $^{230}Th/^{234}U$ disequilibrium method (Table 2). Samples HUTH 1539, HUTH 2215 and HUTH 2237 yielded analytical results indicating a good standard of reliability[8–10], and together suggest a range of travertine deposition ages between 140 and 170 kyr.

In the upper channel, the mammal fauna (Table 1) is a characteristic temperate woodland assemblage, known from many other British sites and apparently restricted to the Ipswichian Interglacial[6,7,11]. Speleothem enclosing a similar fauna in Yorkshire has yielded uranium series dates around 120 kyr BP (ref. 12). Stratigraphical relationships at Marsworth (Figs 2, 3) show that the upper channel-fill overlies the lower. The coombe deposits separating the channel-fills suggest an intervening period of severe periglacial conditions.

Dating of the travertine in the lower channel indicates a pre-Ipswichian age, but one too young to fall within the Hoxnian. In addition, the mammal fauna in the lower channel is unlike faunas of Hoxnian age. *Mammuthus–Equus* faunas occur in middle Devensian contexts[6,7], but differ in composition from that at Marsworth. Sites having *Mammuthus–Equus* assemblages comparable with Marsworth have generally been assigned to the late Ipswichian[6,7]. The Marsworth evidence demonstrates that a pre-Ipswichian age is possible for such assemblages[13,14].

The beetle *A. gibbulus*, which is common at Marsworth, has not been found in faunas of firmly established Hoxnian or Ipswichian age. It occurs very rarely in middle Devensian deposits, but in assemblages unlike that from Marsworth. It is relatively common (G.R.C., unpublished data) in interglacial sediments at Stoke Goldington in the Great Ouse valley, at Aveley in the Lower Thames Valley, and at Stanton Harcourt in the Upper Thames Valley. At none of these sites are the total fossil assemblages comparable with examples of Hoxnian or Ipswichian age.

The Marsworth pollen shows no clear resemblance to established floras of either interglacial or interstadial status. In the Hoxnian and the Ipswichian, *Picea* was scarce, and while *Abies* was present towards the end of the Hoxnian, it was rare or lacking in the Ipswichian[15]. The middle Devensian, Upton Warren Interstadial has a flora with temperate, boreal and arctic–alpine components, with grassland as the major vegetation[16]. In the early Devensian forested interstadials, *Betula*, *Pinus* and *Picea* are the usual tree components and *Abies* is unknown. At High Lodge, in what may be a Wolstonian interstadial context[15], open coniferous woodland occurs with *Betula*, *Pinus*, *Picea* and *Alnus*, Gramineae and open-ground herbs. Despite the variety of these interstadial floras, they all differ from Marsworth.

We conclude that the travertine in the lower channel represents a previously unrecorded interglacial, intermediate in age between the Hoxnian and the Ipswichian. We note in particular that it preserves temperate woodland species. The sediments of the lower channel, which enclose the travertine, indicate a grassland environment. We note the absence of obligate cold species in the contained fossil assemblages, and conclude that the sediments probably represent conditions succeeding those recorded in the travertine, but within the same temperate episode. It is possible, however, that the sediments denote an additional pre-Ipswichian temperate phase of interstadial status.

We thank Tunnel Cement Co. for access to Pitstone no. 3 quarry where this investigation was carried out.

A real-time dynamical forecast of ocean synoptic/mesoscale eddies

A. R. Robinson*, J. A. Carton*, C. N. K. Mooers†, L. J. Walstad*, E. F. Carter*, M. M. Rienecker†, J. A. Smith† & W. G. Leslie*

Energetic eddy currents are the oceanic analogue of atmospheric weather and have time scales of days to weeks and space scales of tens to hundreds of kilometres[1]. We have predicted their evolution in time by internal dynamical processes. For the forecasts we transferred initialization data from ship- to shore-based computers, during two 2-week periods in June and July of 1983 from an approximately (150 km)[2] region in the deep north-east Pacific off California. This is, to the best of our knowledge, the first such real-time forecast at sea. The results were substantially successful; the dynamics predicted a prominent zonal jet absent in the initial flow. Also, the model forecast revealed a strong eddy merger event otherwise obscured in the data. Prospects are encouraging for future forecasting, which should have important implications for research and practical operations at sea[2].

The efficient description and prediction of the flow field in the ocean is necessary because of the difficulty and cost of direct observations due both to the opacity and vastness of the sea and to the natural scales of the phenomena. Modern predictive methodology is developing, guided by related experience in meteorology, astronomy and engineering, and based on optimal estimation procedures. Key issues are data assimilation in dynamical models[3], which involves the regular and synoptic gridding (analysis) of gappy multicomponent data sets, and the understanding of initialization and verification procedures. Our concept invokes a descriptive predictive system[4,5] consisting of an observational network, a dynamical model and a statistical model. The statistical model is an anisotropic mixed space-time objective analysis scheme which depends on east, west and time lags[6]; it is used for initialization and verification analyses for dynamical forecasts. The dynamical model is a baroclinic quasigeostrophic model which interrelates the flow, density and pressure fields. The open (water–water) boundary conditions, which allow the utilization of the model in arbitrarily located regions, require the specification of the normal flow everywhere around the region and the vorticity (horizontal gradients of horizontal flow components) on inflow. The model has been documented, calibrated, and applied to hindcasts of the POLYMODE synoptic/dynamics experiment data[5]. With adequate computational resolution and accurate boundary conditions, the model can forecast its interior domain for months, with a normalized r.m.s. error of only a few per cent[7].

Our 'test block' of ocean, located in the California Current System, is centred at 38°15′ N and 126° W, with a mean depth of 4,200 m. Although close to topographic features, the bottom slope is generally only $0(10^{-2})$ or less in the region. Three surveys in 1982 found highly variable flow consisting of current filaments

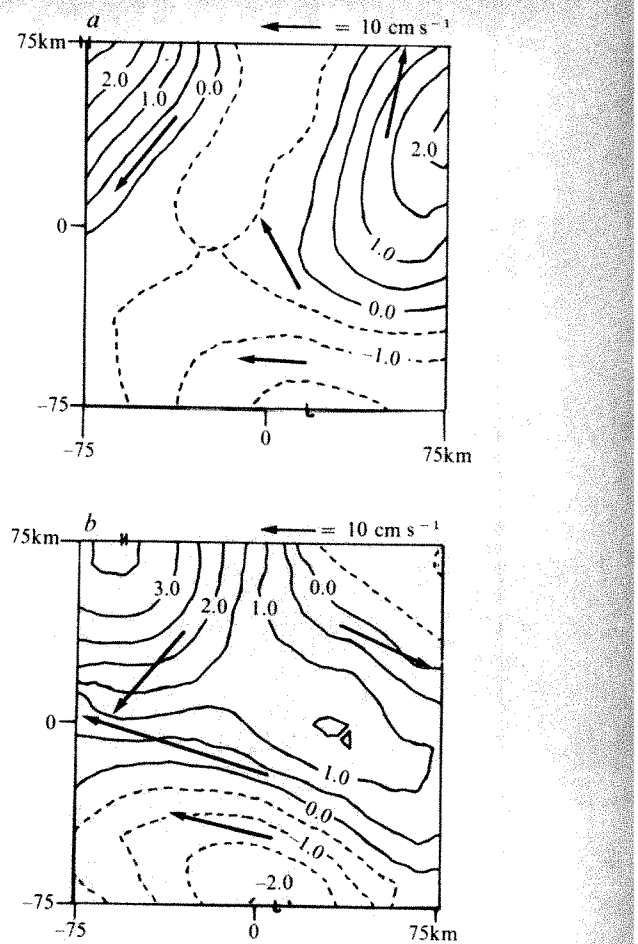

Fig. 1 *a*, Streamfunction (pressure field) at 150-m depth in the main thermocline for Julian day 5506 (20 June 1983), used as the initial condition for forecast and forecast experiment. The centre of the domain is at 38°15′ N, 126° W. The ordinate is rotated 10° west of north. The scale of the streamfunction is 5,000 $m^2 s^{-1}$. Arrows indicate flow speed and direction. The contour interval is 0.5. *b*, As for *a*, Julian day 5520 (4 July 1983) used as verification for both the forecast and forecast experiment, also used in the linear interpolation of boundary conditions for the forecast experiment.

intermingled with cyclonic and anticyclonic eddies. Substantial changes in the flow system can occur within a week[8]. These cruises were carried out to provide the requisite kinematical background for the forecast reported here. In 1983, three hydrographic surveys each of a week duration were obtained 2 weeks apart, to provide two sets of initialization and verification data. Each hydrographic survey consisted of approximately 90 XBT (expendable bathythermograph) measurements of the vertical temperature profile interspersed with 10 CTD (conductivity–temperature–depth) measurements of both the temperature and salinity profiles. Nominal station spacing along the ship track was ~10 km. Temperature and salinity are well correlated in this region so the mean temperature–salinity relationship was used together with the XBT measurements to obtain density profiles and geostrophic currents (dynamic height). Although we plan direct current measurements in future work, the thermocline flow pattern is not sensitive to reasonable assumptions about a geostrophic reference level. Analyses were carried out for each central day by combining data and mapping with a time-independent objective analysis scheme. The first and second analyses are shown in Fig. 1*a*, *b*.

Originally (Fig. 1*a*) the flow in the centre of the region was weak with a strong anticyclonic eddy in the north-east corner, a southwestward current, part of an anticyclonic eddy, in the

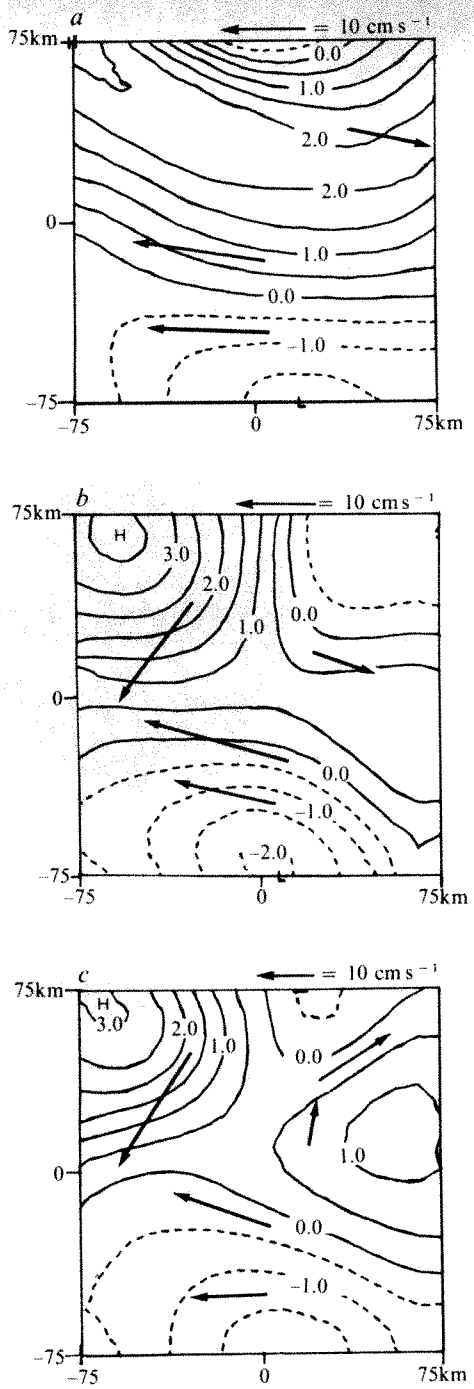

Fig. 2 *a*, Forecast streamfunction at 150-m depth for Julian day 5520 (a 2-week forecast), using persistent boundary conditions (those of Julian day 5506). *b*, Forecast experiment streamfunction at 150 m for Julian day 5520 (a 2-week forecast), using linearly-interpolated boundary conditions (between Julian day 5506 and 5520). *c*, As for *b*, at Julian day 5513 (the forecast after 1 week).

north-west and a segment of cyclonic flow in the southern boundary. Two weeks later (Fig. 1*b*) the flow had dramatically changed; the centre was dominated by a strong zonal jet, the anticylones in the north-west and north-east had apparently merged, and the southern cyclone intensified. After another 2 weeks (not shown), the anticyclonic eddy was further enlarged and the jet, now entering from the eastern edge and oriented towards the south-west, filled the entire central and southern region.

For the dynamical model forecast runs, physical resolution and computational accuracy considerations led to a time step of 3 h, 9 km horizontal resolution and six vertical levels throughout the water column. The hydrographic measurements directly provide only velocity shear in the thermocline, but to initialize the model we need absolute velocity in the thermocline and an estimate of the velocity throughout the water column including the deep water. To estimate the shear below the bottom of the XBT casts, we projected the thermocline flow onto the first baroclinic dynamical mode. The flow in the deep water was then taken to be composed of only the barotropic and first barolinic modes, with an amplitude ratio determined by numerical experiments. Thus determined, the deep flow estimate provides a velocity at 500 m, which was used as a reference value for the thermocline shear. This choice of deep structure, and the ability to estimate the first mode structure from thermocline measurements only, are supported by our related studies with empirical orthogonal functions. After trying different mode ratio assumptions in real time, a barotropic mode was added which had 75% of the energy of the first baroclinic mode and opposed it below the thermocline. This initial mode ratio resulted in the least rapid change of the amplitude ratio of the barotropic to first baroclinic mode at the start of the forecast. The forecasted thermocline flow patterns were in any case found to be insensitive to the assumptions about the mode ratios.

Real-time forecasts were performed by initializing the dynamical model with the analysed data and by simply persisting the initial boundary conditions for the duration of the forecast. Later we performed a dynamical 'forecast experiment' with boundary conditions linearly interpolated in time between the initialization and verification analyses. The forecasts are shown in Fig. 2(*a*, *b*) for the cases of persisted (interpolated) boundary conditions.

During the forecasts the anticyclone in the north-west corner moved into the region, merged with the anticyclone in the north-east corner, which then weakened and disappeared; the small closed contour in the eastern central region of Fig. 1*b* is the remnant of the original north-east corner anticyclone. The southern cyclone enlarged, strengthened and also contributed to the zonal jet. This dynamical behaviour occurred in both the forecast and the forecast experiment and the zonal jet is seen prominently in Figs 1*b*, 2*a*, *b*. The (incorrect) persisted boundary conditions of the forecast alter the flow pattern at the edges and ultimately suppress the north-west corner eddy. However, the forecast experiment with interpolated boundary conditions represents very well the flow pattern and current strengths everywhere. This indicates that the dynamical model can 'project' good resolution boundary data into a rather large domain. Results for the second period were similar.

To illustrate the power of the model as an interpretative physical tool, we show in Fig. 2*c* the flow field a week after the start of the forecast experiment. Without dynamical model interpolation it is impossible to relate unambiguously the synoptic realizations of Fig. 1 separated by only 2 weeks. Figure 2*c* shows the anticyclone originally in the north-east weakened to half its original strength; the jet has formed and the southern cyclone is present. Elucidation of the nonlinear processes inherent in the eddy merger and jet production shown in Fig. 2 will be a contribution to eddy dynamics.

The success of our real-time dynamical forecast is encouraging for the prospects of practical real-time ocean forecasting. The substantial improvement of the dynamical forecast with interpolated boundary condition directs our research now towards: (1) statistical forecasting of the boundary conditions for the dynamical forecast and/or (2) strategies for acquiring new data for boundary condition updating during the forecast. The use of time-dependent objective analysis is essential. The 1983 forecast was a prototype experiment performed as part of the OPTOMA program (Ocean Prediction Through Observation, Modeling and Analysis) which plans a major forecasting experiment in the summer of 1984 when mixed-layer dynamics and satellite imagery will be added to the forecast scheme.

We thank the Office of Naval Research for their support at Harvard and the Naval Postgraduate School.

Light-induced reduction of natural iron(III) oxide and its relevance to phytoplankton

D. A. S. Finden, E. Tipping*, G. H. M. Jaworski & C. S. Reynolds

Freshwater Biological Association, The Ferry House, Ambleside, Cumbria LA22 0LP, UK

Primary productivity in natural waters may sometimes be limited by the availability of iron[1–4]. To understand the process it is necessary to know which form(s) of iron can be utilized by phytoplankton. Here we present evidence, from algal culture work and photochemical experiments, which suggests that the prevalent form of iron in most natural waters—particulate iron(III) oxide—is an adequate source of iron for algae, even though iron is taken up only in its soluble, ionic form[5]. This is because the oxide undergoes light-induced reduction, providing a continuous supply of soluble (available) iron(II). Humic substances (HS), co-precipitated with the oxide, participate in the reduction process by reducing the iron(III) directly and/or by maintaining it in a reducible state. These findings suggest that, at least in freshwaters, cessation of phytoplankton growth is rarely due to lack of iron.

The uptake of iron by phytoplankton, and the possibility of iron-limited growth, depend on the chemical speciation of the element[5–7]. It has usually been assumed that algae take up soluble ionic species. However, the stable form of iron in oxic waters of neutral or near-neutral *p*H is Fe(III), which has a low solubility[8]. Therefore, algal growth might cease or be severely curtailed if, after initial growth had used up the small amount of soluble (available) iron, its replenishment was slow in relation to the further demands of the algae[5]. Whether such a situation actually arises depends on the lability of those iron species which, although unavailable *per se*, can be converted into available forms.

In algal culture work, iron is commonly added in a soluble chelated form, such as Fe(III)–EDTA[9]. Such chelates are thought to allow iron to be taken up efficiently through photodecomposition, whereby the chelated iron is reduced and released as soluble Fe(II)[10]. The latter can then be utilized by algae, either directly or after oxidation to ionic Fe(III) forms[5,11].

It has been suggested[5] that the natural chelators for Fe(III) are HS. Although there is no firm evidence for soluble Fe(III) chelates in neutral or alkaline waters, iron oxides adsorb HS[12] and HS co-precipitate with natural iron oxide[13]. Furthermore, at acid *p*H values Fe(III) is readily reduced when HS are present, especially when exposed to light[14]. These facts prompted us to test naturally-occurring iron oxide for light-induced reduction and as an iron source for the common green alga *Monoraphidium contortum* (Thur. in Bréb.) Komárková-Legnerová. We believe this to be the first study of a well-characterized naturally-occurring form in relation to algal iron nutrition.

The natural iron oxide, ~10% by weight HS, accumulates in the hypolimnion of Esthwaite Water in Cumbria, UK, during the summer, being formed through the oxidation of Fe(II) diffusing out of the sediment. The sample used in this work was collected from 1 m above the sediment of Esthwaite Water in July 1983, and was kept at neutral *p*H in the dark at 6 °C before use. Details of material sampled on earlier dates are given in ref. 13.

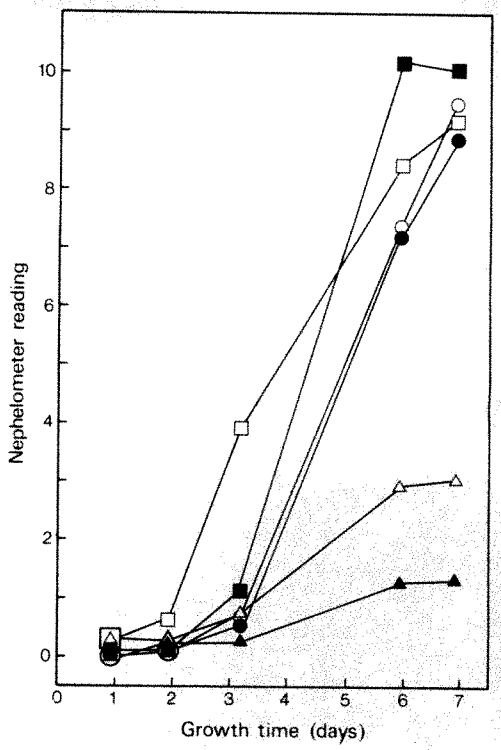

Fig. 1 Growth of *Monoraphidium* on various forms of Fe(III): Esthwaite Water iron oxide (○), synthetic Fe(III)–HS co-precipitate (●), Fe(III)–EDTA (□), fresh ferrihydrite (■), aged ferrihydrite (△), no added iron (▲). The algal growth medium consisted of NaCl, KNO_3, $MgSO_4$ and $CaCl_2$ (all 10^{-3} mol dm^{-3}), KH_2PO_4 (10^{-4} mol dm^{-3}) and Na_2CO_3 (7.5×10^{-4} mol dm^{-3}). When equilibrated with the atmosphere the *p*H was 8.1–8.2. The medium was filtered (0.22 μm Nuclepore) before the addition of iron (2×10^{-6} mol dm^{-3}). Aliquots (10 cm^3) of medium were inoculated with a cultured strain of *Monoraphidium* (L188 from the Freshwater Biological Association Culture Collection; original isolate from Lough Neagh, 1969) at a concentration of $\sim2\times10^7$ cells dm^{-3}. Before inoculation the *Monoraphidium* had been grown to the stationary phase in the same medium with 10^{-6} mol dm^{-3} fresh ferrihydrite as the iron source. The concentration of iron in the experimental tubes due to carry-over in the inoculum was $\sim10^{-8}$ mol dm^{-3}. The inoculated aliquots were contained in transparent polycarbonate tubes and were bubbled continuously with wet air to maintain constant *p*H and P_{CO_2}. The tubes were incubated at 20 °C and illuminated with light (400–700 nm) at 216 μEinstein m^{-2} s^{-1} supplied from below by 4 × 40 W daylight fluorescent tubes. Algal growth was assessed by nephelometry, the scattered light being directly proportional to the concentration of cells in the range 0–3×10^9 cells dm^{-3}: a nephelometer reading of 10 (arbitrary units) corresponds to 1.5×10^9 cells dm^{-3}.

As well as the natural oxide, other forms of Fe(III), were tested. Aged ferrihydrite[15] was prepared by neutralizing $Fe(NO_3)_3$ with NaOH and keeping the precipitate at *p*H 7 for 4 months at 6 °C in the dark. Fresh ferrihydrite was obtained by addition of a solution of $Fe(NO_3)_3$ directly to the culture medium in algal cultures or to the Tris-HCl buffer in the photochemical experiments (see below). A synthetic Fe(III)–humic co-precipitate (HS/Fe = 2, by weight) was prepared by oxidizing $FeSO_4$ in the presence of Penwhirn Reservoir HS[16] and was stored in the same conditions as the aged ferrihydrite. Colloidal haematite (α-Fe_2O_3), goethite (α-FeOOH) and lepidocrocite (γ-FeOOH) were synthesized by methods given in refs 17, 18

Table 1 Reaction of different forms of Fe(III) with bathophenanthroline disulphonate (BPDS)

Form of Fe(III)	% Fe reacted with BPDS after 16 h	
	Light	Dark
Esthwaite Water iron oxide	6	2
Fe(III)–HS co-precipitate	7	2
Fe(III)–EDTA	34	0
Ferrihydrite Fresh	39	11
Aged	2	1

Iron samples were incubated at a concentration of 2×10^{-4} mol dm^{-3} in 5×10^{-4} mol dm^{-3} BPDS and 0.02 mol dm^{-3} Tris-HCl at *p*H 8.15 and 20 °C. When applied, illumination was as in the algal culture experiments (Fig. 1). The formation of Fe–BPDS complexes was monitored by spectrophotometry at 536 nm. No reduced iron was detectable at zero time.

and 19 respectively. The Fe(III) chelates of EDTA and the siderophore desferrioxamine B[20] were prepared with the chelates in twofold molar excess.

Figure 1 shows that, with a light regime which simulates natural conditions reasonably well, and at a total iron concentration (2×10^{-6} mol dm^{-3}) typical of natural waters, good growth of *Monoraphidium* was obtained with four of the forms of iron studied; Fe(III)–EDTA, the synthetic Fe(III)–HS co-precipitate, the fresh ferrihydrite and the natural Esthwaite Water iron oxide. The aged ferrihydrite was less effective but gave slightly better growth than was obtained with no added iron. Neither the crystalline oxides nor the Fe(III)–desferrioxamine B chelate improved growth.

Table 1 shows the results of photochemical experiments in which the different forms of iron were incubated, either illuminated or in the dark, at the same *p*H (8.15) as the algal cultures, in the presence of bathophenanthroline disulphonate (BPDS). BPDS strongly complexes Fe(II) and so would trap any Fe(II) produced before re-oxidation[5,8,11]. The results for Fe(III)–EDTA are consistent with the well-established photodegradation of the chelate to give Fe(II) (ref. 10). The results for the other four types of iron which enhance algal growth are less clear-cut because in each case iron was to some extent trapped by BPDS in the dark. The dark-iron–BPDS reactions were probably due to the complexation by BPDS of the relatively labile Fe(III), followed by reduction to the BPDS–Fe(II) complex[21] or, when HS were present, due to the reduction of the iron to Fe(II) which then reacted with BPDS. Notwithstanding the reactions in the dark, however, the enhanced production of BPDS-complexed iron when the samples were illuminated indicates that these Fe(III) species each underwent light-induced reduction to give Fe(II) which was subsequently trapped by BPDS. No Fe–BPDS complexation occurred with the crystalline oxides, nor with the Fe(III)–desferrioxamine B chelate.

The results in Table 1 and Fig. 1 show that those forms of Fe (III) which undergo light-induced reduction also support the growth of *Monoraphidium*, in accord with the hypothesis that algae utilize soluble, ionic iron. The Fe(III)–desferrioxamine B chelate is neither reduced nor does it support growth, showing that iron uptake does not depend merely on solubilization.

The results for the humic-free ferrihydrite samples show that HS are not essential for the production of Fe(II). However, the susceptiblity of ferrihydrite to reduction decreases quite rapidly with time, as shown by the results for the fresh and aged samples in Table 1, and also by the observation that only 2 days' ageing at *p*H 8.15 was sufficient to decrease by 80% the amount of Fe trapped by BPDS in 16 h in illuminated conditions. In contrast, the synthetic Fe(III)–humic co-precipitate, in which the iron appears (by transmission electron microscopy) to be present largely as ferrihydrite, was both more readily reduced and better at supporting algal growth than the aged humic-free ferrihydrite, although the two samples were prepared at the same time and stored in the same conditions. The difference might be explained by the co-precipitated HS inhibiting the ageing of the ferrihydrite, or it may be that HS directly reduce aged ferrihydrite under illumination[14].

Irrespective of their mechanism(s) of action, however, we conclude that co-precipitated HS can maintain the susceptibility of iron(III) oxide to light-induced reduction, and that this prolongs the availability to algae of Fe(III). The possible role of HS in making iron available was discussed by Shapiro[6], but in terms of peptization of colloidal particles rather than reduction of Fe(III). The beneficial effects of HS on the growth in culture of a variety of algae[22–25] may well have been due to the HS making iron more susceptible to reduction.

Wells *et al.*[26] considered that algal uptake of iron from synthetic iron(III) (hydr)oxides was related to the rate of (light-independent, non-reductive) dissolution of the solid. However, at neutral or alkaline *p*H, dissolution due to light-induced reduction is likely to be of much greater significance.

The mechanism for making iron available to algae demonstrated by our results is similar to one suggested[27] in relation to manganese uptake by marine phytoplankton, which was based on observations of light-induced reduction by marine HS of synthetic manganese dioxide.

In the epilimnion of Esthwaite Water, much of the particulate iron is present as amorphous iron(III) oxide particles similar in appearance and size to the hypolimnetic material studied above[28]. Assuming that the epilimnetic iron is similarly susceptible to reduction, then at any one time during the summer months there is a large pool of iron (10^{-6}–3×10^{-6} mol dm^{-3}) which can be made available to algae. The pool is continually replenished by iron oxide brought into the lake in inflows or diffusing upwards from the deep water or sediment. It is thus difficult to see how, in this lake, algal uptake could exhaust the supply of iron to the point where further growth was demonstrably iron-limited. Whether this applies to other natural waters remains to be seen. The effects on iron supply of total iron concentration, *p*H and light intensity require investigation, and other natural iron oxides need to be tested for light-induced reduction. Clearly, however, substantiation of suspected iron limitation in nature must take account of the reducible iron oxide pool in relation to the modest iron requirements of planktonic algae.

A new Lower Devonian plant and the early evolution of leaves

Patricia G. Gensel

Department of Biology, University of North Carolina, Chapel Hill, North Carolina 27514, USA

The fossil record suggests that, by the end of the early Devonian, vascular plants had diversified considerably but they were still relatively simple in their organization[1-3]. Most exhibit much-divided aerial shoots arranged in various patterns but lack clear differentiation into stems and leaves. I describe here a novel plant, discovered in the upper Lower Devonian of Gaspé, Quebec, Canada, whose anatomy is more complex and indicates a level of stem–leaf differentiation significantly more advanced than any known for trimerophytes or other taxa of this age. The presence of a lobed xylem, with mesarch protoxylem elements in major axes, and an elliptically shaped trace in first-order lateral axes in the new plant suggests that by the end of the early Devonian, the evolution of megaphyllous leaves has indeed begun, even though morphologically they were still much divided and non-laminate.

The anatomy of most vascular plants from the Lower Devonian consists of a solid terete or elliptical cylinder of tracheids with centrarch or exarch primary xylem maturation (except in lycophytes or lycophyte precursors with vascularized microphyllous leaves and lobed xylem). A variety of sporangial shapes and modes of attachment (terminal, lateral) occur and some possess unvascularized, usually multicellular emergences. No secondary tissues other than wound tissue are known and reproduction was homosporous or incipiently heterosporous. In contrast, middle and late Devonian plants show the first appearance of more complex stelar patterns, some morphological and/or anatomical distinction between stems and megaphyllous leaves, secondary tissues, arborescence, heterospory and the seed habit. By then, many major plant lineages had become evident, some of which can be linked, at least indirectly, to modern plant groups.

The new plant described here is represented by compression and permineralized specimens collected from the Battery Point Formation near Seal Rock Landing on the north shore of Gaspé Bay, Quebec, Canada. The age of the sediments is determined by dispersed spores which represent McGregor's *caperatus–emsiensis* dispersed spore assemblage zone[4] of early Emsian age. On some compressions, short lengths of axes are permineralized by pyrite or limonite. Some axes also occur in isolated pyrite nodules. So far, only vegetative remains have been found in attachment, although associated fertile organs occur.

The new plant, although similar in external vegetative morphology and complexity to the contemporaneous (Lower Devonian) trimerophyte genera *Pertica*, *Trimerophyton* and, to some extent, *Psilophyton*[5-7], differs significantly on close examination in details of branching pattern (Fig. 1*a*, *b*) as well as anatomy. The major axes, 0.7–1 cm wide, bifurcate into two equal-sized units (Fig. 1*b*, B). Each of these divides equally (isotomously) again or unequally (anisotomously) to produce distantly spaced, spirally arranged lateral branches (Fig. 1*b*, L). The latter divide anisotomously either just above their point of departure or more distally to produce small third-order axes. These divide one to three times and, where complete, terminate in recurved tips. All axes are covered with short (0.3–0.6 mm) hairs which are represented by punctiform scars on axis impressions.

The xylem consists of primary tissues forming a deeply three-lobed protostele (Fig. 1*c*). Three protoxylem areas, one near the end of each arm, are present, and a fourth is often located in the centre (Fig. 1*c*). This type of xylem was observed from sections of the major axes above and below isotomous bifurcations, at the points indicated in Fig. 1*b*.

Xylem maturation thus is mesarch; the protoxylem elements commonly are broken down to form lacunae. Protoxylem areas sometimes appear linked by a band of small cells which probably represent compressed metaxylem elements. The latter exhibit scalariform thickenings or oval and circular pits on all walls (Fig. 1*d*).

Lateral traces are helically arranged. Formation of a lateral trace involves: (1) tangential enlargement of the end of a xylem lobe, first to one side and then the other (Fig. 1*f*, *g*), (2) enlargement and division in protoxylem tissue (Fig. 1*g*, *h*) and (3) separation of outer protoxylem and associated metaxylem elements (Fig. 1*h*, *e*). The tangentially elongate lateral trace usually remains elliptical in shape, with centrally located protoxylem, after leaving the cortex. These traces supply the lateral branches resulting from anisotomies (branches labelled L in Fig. 1*b*).

No early Devonian plant exhibits this particular combination of a lobed vascular strand, mesarch primary xylem maturation and type of lateral trace production. Several groups of middle Devonian plants, namely the Aneurophytales (Progymnospermopsida), Iridopteridales (sensu Stein, 1982) and Cladoxylales[8-13] have variously lobed xylem with protoxylem lacunae surrounded either by remnants of protoxylem or by metaxylem. In these plants, vascular traces to lateral branches usually depart from the lobe tips; at some level the lateral traces differ from the parent axis in size or shape and where different are believed to indicate the presence of leaves. These plants can be distinguished from each other and from the new plant in number and location of protoxylem areas, shape and mode of production of lateral traces, and in the presence (in aneurophytes) of secondary tissues. The new plant might be regarded as a trimerophyte derivative leading towards certain of these younger plant groups, such as the Aneurophytales or Iridopteridales. Other plant groups such as the Cladoxylales and/or ferns probably evolved independently from a trimerophyte ancestor, perhaps at different times.

The anatomy of the new plant offers evidence concerning differentiation of stems leading to the establishment of leaves. In most early Devonian plant groups, evolution of megaphyllous leaves is regarded as being at a very early stage, manifested mainly as variability in branching patterns of stem-like axes. Plants with undoubtedly laminate, megaphyllous leaves occur in the Upper Devonian[14,15], although rare occurrences of incompletely preserved laminate, apparently megaphyllous leaves (*Platyphyllum*) of uncertain affinities have been reported from the Emsian[1,14]. It has been postulated[16,17] that the trimerophytes exhibit early transitions of branch systems to megaphyllous leaves, as follows: (1) in *Psilophyton*, variation in dichotomous to pseudomonopodial branching patterns; (2) in *Pertica* and *Trimerophyton*, the development of a distinct, robust major axis with subordinate lateral branches; and (3) in the latter two genera a tendency for regularly arranged, but pseudomonopodially divided lateral branches. Where anatomy is known, no major change in vascular strand shape occurs in the various orders of branching, except for a slight difference in shape in strands departing to fertile branches in *Psilophyton dawsonii*[16]. The new plant demonstrates a pronounced anatomical change from the lobed xylem of the main axis to an elliptically shaped, first-order lateral branch trace. Comparable changes in vascular strand shape in younger fossil plants, or extant ones, occur between stem and leaf.

The transition from an elliptical centrarch xylem strand, typical of trimerophytes, to a lobed, mesarch one as is present in the new plant and several Middle–Upper Devonian ones of various affinities is here considered possible by loss during development of centrally located protoxylem, leaving separate peripheral strands, and by variable metaxylem development. An intermediate condition may occur in *Psilophyton dawsonii* in those axes from which numerous vegetative branches depart in quick succession and which exhibit a somewhat lobed protoxylem region and irregularly shaped metaxylem. Additionally, a lobed xylem with protoxylem areas in the lobes, as found in the

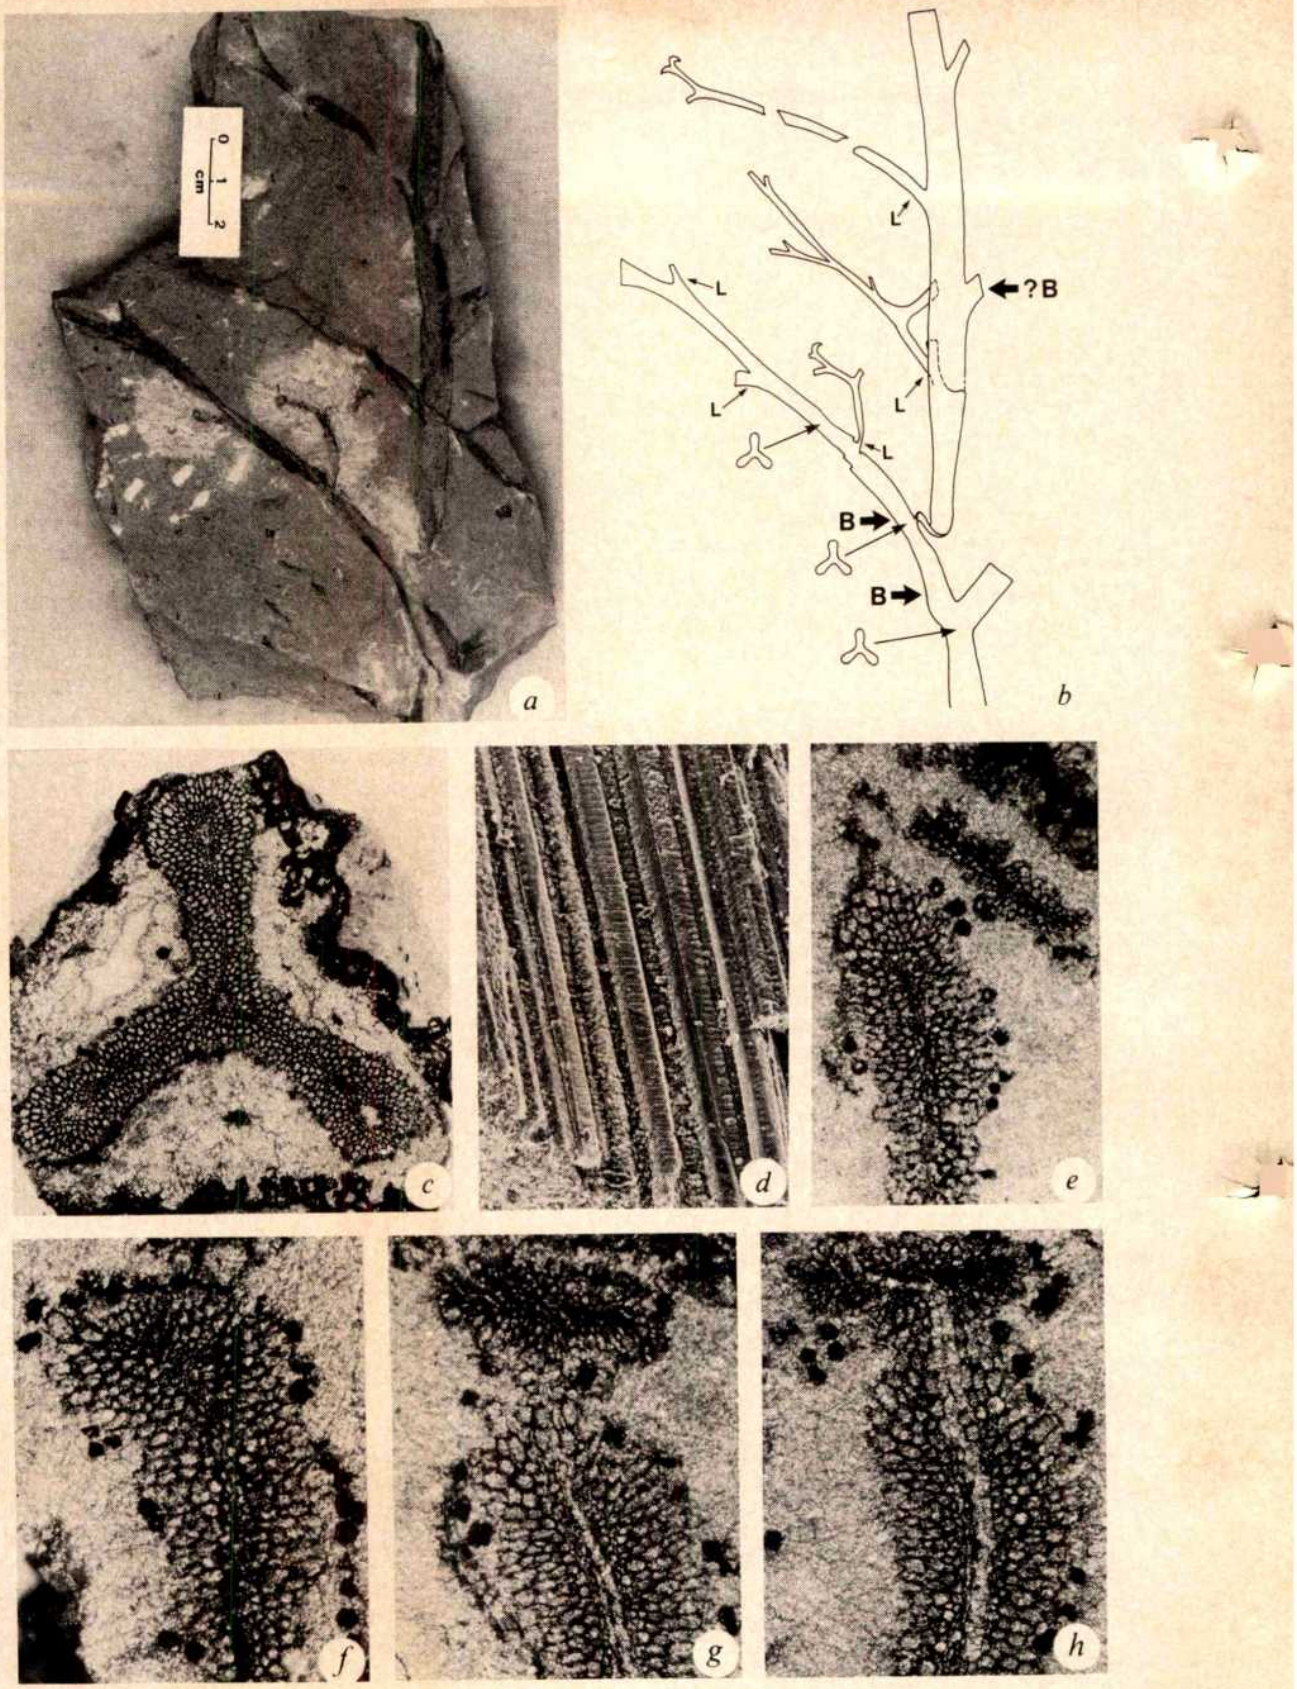

Fig. 1 *a*, Compression/impression showing major components of branching: note two equal bifurcations of the main axis near the base, and production of lateral branches distally. *b*, Line drawing based on tracing photographs of part and counterpart of specimen in *a*. The lateral branch in the middle of the drawing was exposed by splitting of the upper portion of the specimen in *a*. new plant, may be linked to the very regular pattern of lateral branch departure. In view of this evidence, it is interesting to consider once again what type of xylem existed in plants like the trimerophytes *Pertica* and *Trimerophyton*, which also show a regular pattern of lateral branch departure.

In summary, the new plant, while resembling known Lower Devonian plants in general morphology, is more complex anatomically but can be logically derived from them. Further, it suggests that appendicular structures or leaves were already being differentiated at that time, even though morphologically they still were much divided and non-laminate.

Recurrent patterns of natural selection in a population of Darwin's finches

Trevor D. Price*, Peter R. Grant*, H. Lisle Gibbs* & Peter T. Boag†

* Division of Biological Sciences, Natural Science Building, University of Michigan, Ann Arbor, Michigan 48109-1048, USA
† Department of Biology, Queen's University, Kingston, Ontario, Canada K7L 3N6

The adaptive significance of morphological traits can be assessed by measuring and identifying the forces of selection acting on them. Boag and Grant[1] documented directional selection in a small population of Darwin's medium ground finches, *Geospiza fortis*, on I. Daphne Major, Galápagos, in 1977. Large beak and body size were favoured at a time of diminishing food supply and high adult mortality. We show here that in two subsequent periods of moderate to high adult mortality (1980 and 1982), the population was subject to the same selection. We have used a recently developed technique[2] to ascertain the targets of direct selection. Beak depth and body weight were commonly under direct selection to increase but, surprisingly, beak width was directly selected to decrease, over all three periods of mortality. The results have implications for our understanding of evolutionary change in morphological traits of Darwin's finches[3–6].

We consider three 18-month periods of adult disappearance, mainly due to mortality[1,3], between June 1976 and December 1982 (Table 1). Each period was associated with a year of low rainfall (Table 1). Less than 5% of adult mortality occurred in the remaining 24 months (January 1978–June 1979 and January–June 1981). Only adults (at least 1 year old) which had been ringed and measured before the periods of high mortality are included in the analyses. Survival of ringed and measured birds was assessed by a detailed census at the end of each period[1,3]. Seed abundance was estimated at this time by counting seeds on plants and in the soil in 50 randomly placed quadrats[1,3]. Four characters (body weight in grams, and beak length, beak depth and beak width in millimetres) have been measured by different observers in a consistent fashion[3,4]. The characters are highly and significantly positively correlated[4–6]. Before each analysis, data were $\log_e$-transformed and then standardized to have zero mean and unit variance.

Table 2 shows the vectors of directional selection differentials (s) and the directional selection gradients (β)[2] associated with mortality in each of the three periods. A selection differential is the difference between the mean value of the character before and after selection, here measured in standard deviation units. The selection gradient comprises the partial regression coefficients of relative fitness (survival) on each character. Relative fitnesses are obtained by dividing absolute fitnesses (0 or 1) by the mean absolute fitness[2], that is, the proportion surviving. Thus, each partial regression coefficient measures intensity of selection acting directly on each character, apart from phenotypic responses due to selection on other correlated and measured characters[2]. After 1978 the ages of birds were known, so we repeated the analysis separately for each age cohort to test for age-specific effects (Table 3).

For all characters and periods, selection differentials are significantly positive, or they are not significantly different from zero: survivors are often larger than those individuals that disappear (Tables 2, 3). The most intense selection in this direction was in 1976–77, when the lowest number of individuals (15%) survived (Table 2). The selection gradients indicate that increases in all measured characters are due almost entirely to selection on beak depth and/or body weight (or to selection on an unmeasured character with which these are highly correlated). Beak length is usually not a target of direct selection, but it increases as a correlated response to selection on beak depth and/or body weight. The partial regressions of relative fitness on beak width are usually negative and often significant: this result was not expected in view of the net increases in the sizes of all traits in 1976–77. Thus, beak shape, as well as size, is subject to selection.

In each of the three periods of mortality, partial regression coefficients of relative fitness on beak depth and body weight are positive and partial regression coefficients of relative fitness on beak width are negative (Tables 2, 3). When the selection over the 1977 drought is divided into three consecutive 6-month periods, this pattern is observed within each period (Table 4). It is also observed when selection on each sex is analysed separately[5].

The repeatedly observed direct selection favouring a small beak width was often intense. It was sufficient to counteract strong selection favouring large beak depth and/or body weight in the 1978 cohort in both 1979–80 and 1981–82, resulting in small selection differentials for all characters, but not in the pre-1976 cohort in 1981–82 (Table 3).

Selection events can be interpreted in terms of feeding conditions. Seed supplies decline during a drought[1], but hard seeds are proportionally common (Table 1). Only the larger individuals can crack these seeds[1,7,8]. Among these large individuals, efficiency at cracking the woody *Tribulus* fruits is a positive function of beak size[7]. Selection for large beak and body size associated with starvation has previously been related to the superior seed handling ability of large individuals[1]. The demonstration here that beak depth is a direct target of selection strengthens this interpretation.

A plausible hypothesis for the selection to decrease beak width is that a relatively narrow beak is favoured in the specialized feeding on *Tribulus* fruits: individuals crack the fruits by placing the side of the beak across a corner and twisting[7]. *Tribulus* is an important food for *G. fortis* during droughts because it remains common (Table 1) and, unlike *Opuntia*, is not defended or consumed by the cactus ground finch, *Geospiza scandens*, the only other common finch on the island. *Tribulus cistoides* may have been introduced to the Galápagos in the past 450 yr[7,9]. If so, the directional selection pressures on beak width that we have detected are relatively new.

This study has shown that selection repeatedly favours individuals with large beak depth and/or body weight in recurring drought conditions. It has also uncovered an unsuspected

Table 1 Selection periods, population sizes before and after each selection period, and seed biomass at the end of drought years (g per 50 m²)

Drought year	Period studied	Rainfall (mm)	Population sizes		Seed abundance		
			Before	After	Small seeds	*Opuntia echios*	*Tribulus cistoides*
1977	June 1976 to December 1977	24.0	1,200	200	1.2	13.6	117.9
1980	June 1979 to December 1980	53.5	260	210	1.7	184.2	130.6
1982	June 1981 to December 1982	51.1	200	150	0.5	21.0	38.6

Seeds are divided into miscellaneous small seeds, and a medium-size seed (*Opuntia*) and a large seed (*Tribulus*), both of which require significant force to crack and cannot be handled by all the finches[1,7,8]. All rain fell in January–May of each period.

Table 2 Standardized selection differentials (s) and standardized selection gradients (β) for periods of mortality

	1976–77		1979–80		1981–82	
	s	$\beta \pm$ s.e.	s	$\beta \pm$ s.e.	s	$\beta \pm$ s.e.

The periods were defined by the times at which a census of surviving finches was taken. The data were not re-standardized from the first selection period. Significant values ($P < 0.05$) are underlined.

opposing selection in favour of small beak width. Given the high heritabilities of these characters[4,10], there is a strong potential for microevolutionary change between generations. The potential is realized[4], but only to a small degree for two reasons. First, there is a high positive genetic correlation, estimated to be between 0.9 and 1.0 (refs 4, 6), between the two beak traits that are selected in opposite directions. Second, net selection on beak depth and body weight over a whole life cycle is probably small because of opposing selection pressures at other stages of the life cycle, most notably in association with juvenile mortality: small individuals have a selective advantage over large individuals in their first 2–10 months, apparently for metabolic reasons[3].

Results of the study support an adaptive interpretation given

to beak size and shape in this population of Darwin's finches[6,11–13].

Functions of the canal system in the rotaliid foraminifer, *Heterostegina depressa*

Advanced fossil and living rotaliacean foraminifera are characterized by canal systems located within the walls of their plurilocular calcareous tests. Although these canals were described in detail during the nineteenth century[1–4], their biological functions have remained obscure. A study of the Recent nummulitid, *Heterostegina depressa*, has now illuminated the role of the canal system and allowed us to interpret similar structures seen in related foraminifera of Tertiary age. It proves to be a structure of fundamental importance for locomotion, growth, excretion, reproduction and protection.

Although foraminiferal tests are characterized by a multiplicity of shapes, wall structures and construction materials, in only a few taxa do we understand their functional roles well enough to demonstrate relationships to feeding methods or environments (substrates)[5,6]. The only group in which structural features can be explained as convergent adaptations to special modes of life are the larger symbiont-bearing benthic foraminifera (that is, members of the Miliolacea and Rotaliina). The transparency of the test wall and the high ratio of surface area to volume in those with flattened tests, provide the morphological basis for a highly advantageous algal–foraminiferal symbiosis[7–9]. We have examined the canal system within the symbiont-bearing Recent nummulitid, *H. depressa*, in which the test walls replace the primary aperture seen in other foraminifera.

H. depressa d'Orbigny inhabits the warm, shallow, nutrient-poor seas of the tropics and subtropics, where the light flux is relatively uniform throughout the year. This species exhibits marked physiological and morphological trimorphism: gamonts are up to 4 mm in diameter, while agamonts are up to 20 mm and schizonts up to 3 mm across. Although laboratory cultures[10] in which all three forms reproduced were a prerequisite for this investigation, specimens from the sea around Hawaii were also used.

In most multilocular foraminifera, successive chambers are connected by a single foramen, the last-formed chamber opening into the surrounding medium through the terminal foramen (aperture). Many species of rotaliid foraminifera have canal systems of different kinds within the chamber walls, and in genera such as *Operculina* these canals allows communication between the undivided chamber cavities and the lateral surfaces of the test. The subdivided chamber cavities (chamberlets) of *Heterostegina* communicate with the lateral surfaces in a similar manner. Nummulitids also have a three-dimensional network of canals (continuous with the rest of the canal system) within the thickened peripheral keel (marginal cord), and this opens into the ambient seawater.

It is known that nummulitids do not usually have true primary or secondary apertures[11], and few, if any, type descriptions of *Heterostegina* species establish their presence. This is not surprising, since the canaliculate marginal cord together with the canals of the chamber and chamberlet walls serve as an effective substitute. We have, however, observed apertures of various shapes and sizes in at least some individuals (see ref. 12).

The morphology of the canal system has recently been investigated by optical and scanning electron microscopy, and its genesis explained; it has also been used taxonomically[9,11,13,14]. The canal system permits the extrusion of pseudopodia from any point of the marginal cord, even when protoplasm has been retracted from the peripheral chambers. We regard this as its primary function, since it provides the animal with a physiological radial symmetry. In foraminifera lacking a canaliculate marginal cord, pseudopodia emerge only from a single point in the test (the aperture), and then only if the protoplasm has not been retracted from the last chamber. As the extrusion of pseudopodia is the primary function of the aperture in other groups of foraminifera, it seems likely that its secondary functions are also taken over by the canal system in the Nummulitidae. That this is so is demonstrated here for the first time.

In *H. depressa*, the terminal openings of the canals in the marginal cord function as a multitude of small primary apertures and extrude protoplasm which forms the template for the new chamber (Fig. 1). Although this process has been described previously[12], only since it was recorded on film[15] has the significance of the canal system been appreciated. Nummulitids such as *H. depressa*, *Heterocyclina tuberculata* Hottinger and *Operculina ammonoides* (Schröter) would probably be unable to construct large chambers with only a single exit for protoplasm.

H. depressa is nourished by photosynthates obtained from symbiotic algae contained within the cell, and by the continuous digestion of a proportion of the total population of symbionts[16]. Digestion occurs throughout the test, and waste products are transported by the protoplasm from older to younger chambers. Eventually, they are excreted through the openings in the marginal cord on the terminal chamber (Fig. 2) and through the aperture where this exists. The canal system thus provides for the removal of waste matter.

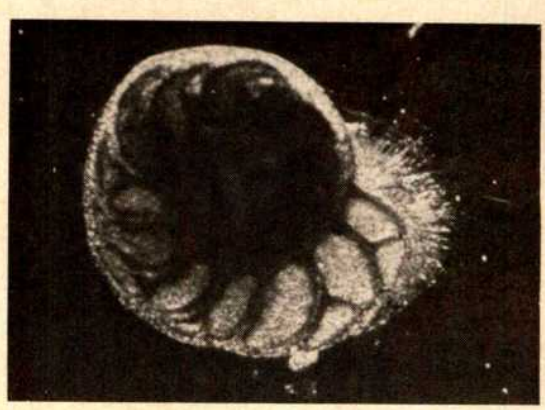

Fig. 1 Process of chamber formation in *H. depressa*. Protoplasmic filaments in large numbers emerge from the canals of the marginal cord of the youngest chamber in order to construct the template of a new chamber. Size of specimen 900 μm.

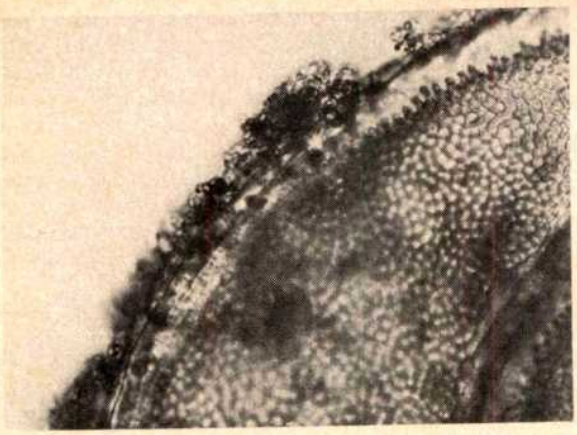

Fig. 2 Part of the lateral surface of the youngest chamber of *H. depressa* with accumulations of excrement on the marginal cord of the test. The 1–2 μm-sized grains have been excreted through the canals of the marginal cord.

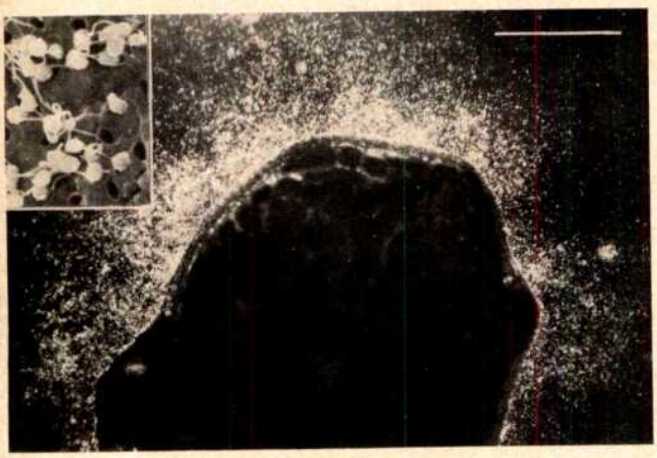

Fig. 3 Gamont of *H. depressa* from 100 m water depth off Honolulu, Hawaii, releasing gametes (scale bar, 420 μm). Inset: The scanning electron micrograph of the test surface shows pores and biflagellate gametes which were released through the canals. Size of the gametes 1 μm owing to shrinkage during fixation; size of living gametes 2.5 μm.

The canal system also functions during sexual reproduction. The 2.5-μm gametes are released mainly through the canal system of the marginal cord (Fig. 3). During asexual multiple fission of the schizont and agamont, the protoplasm, along with the symbionts, evacuates the test and subsequently divides into hundreds or thousands of daughter cells in the ambient seawater. Microcinematographic time-lapse photographs[17] have shown that the protoplasm emerges from the lateral surfaces of the parent test via the canal system (Fig. 4*a–c*). The symbiotic diatoms undergo severe deformation as they are transported through the 2–3-μm wide sutural canals. This is possible because they do not possess silica frustules but only membranous cell envelopes; normally, they are 8–11 μm long, 4–5 μm wide and very variable in shape[18]; they are thus well-adapted to this mode of transport. The outflow of the entire protoplasm through the long and narrow canal system takes a comparatively short time (38 min–4 h 16 min).

Throughout most of its life, *H. depressa* is covered by a transparent sheath attached to the substrate by elastic processes. This prevents transport in turbulent water and also protects the chambers during the growth phases which occur internally. Immature individuals leave their sheaths at intervals and replace them with larger ones[12,19,20]. Light microscope observations show that the secretion of the sheath lasts only a few hours, the material being passed through openings of the canal system onto the surface of the test. The canal system as a whole may therefore be said to provide the morphological basis for the rapid formation of this organic protective structure.

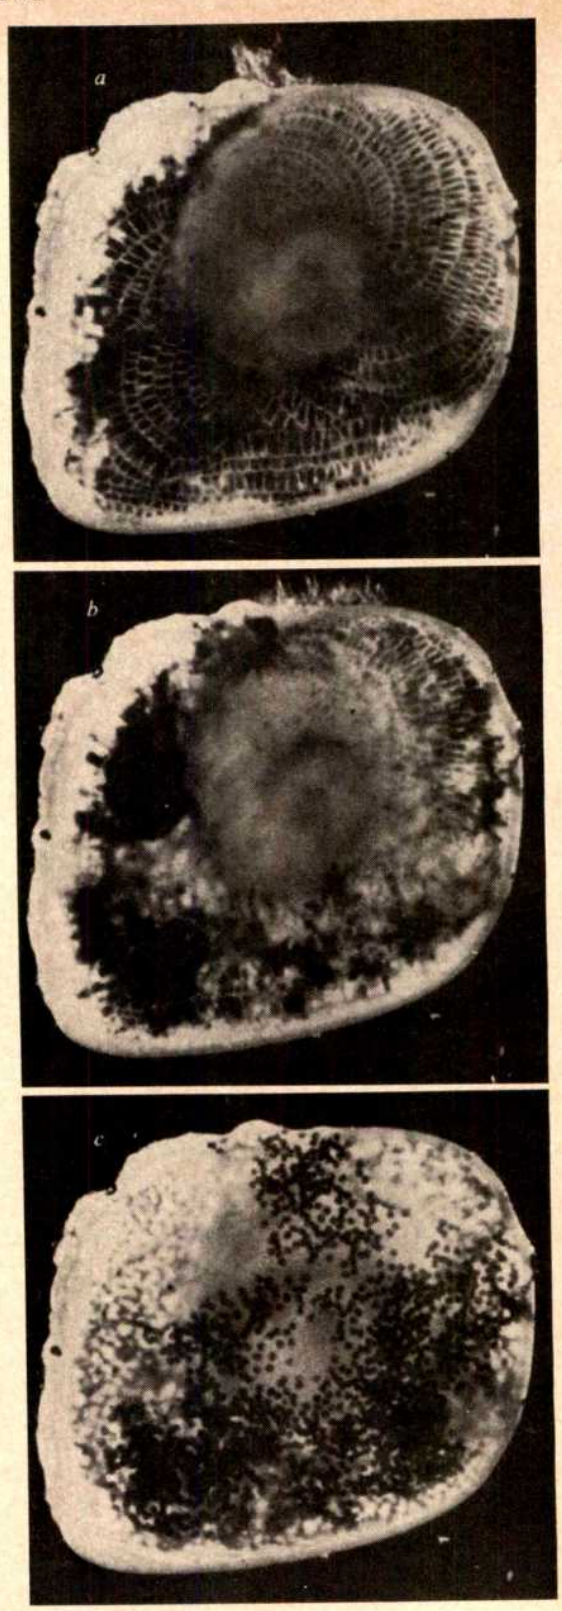

Fig. 4 Microcinematographic shots[17] of an agamont of *H. depressa* from 45 m water depth, Island of Maui, Hawaii (size 9.8 mm). The protoplasm emerges from the test and then divides into the daughter cells. *a*, The protoplasm has retracted from the peripheral part of the calcareous test, thus indicating the beginning of multiple fission. Its dark coloration, caused by the symbiotic diatoms, contrasts with the colourless walls of the chambers and chamberlets. *b*, The protoplasm has evacuated most of the test through the canal system, and now covers both lateral surfaces. *c*, The protoplasm has divided into the daughter cells. Juveniles lying below the maternal test are also visible. Duration of evacuation process 2 h 17 min.

The canal system thus proves to be important for all the principal biological functions of the protoplasm.

Although the flattened and translucent nummulitid test is well adapted to its function as part of a symbiotic association, it also encloses a large volume of protoplasm (plus symbionts) that has to communicate with the outside world. This connection is effected by the canal system which provides physiological continuity between the internal protoplasm and the surrounding seawater.

We thank Professor J. Resig, Dr E. Chave, Professor P. Hallock Muller, Dr T. Burch and B. L. Burch for providing living specimens; the Botany Department and the Blue-Water Marine Laboratory (both University of Hawaii) for providing working facilities; and Professor J. W. Murray and Dr C. G. Adams for discussion. This work was supported by grants from Deutsche Forschungsgemeinschaft and Max Kade Fdn Inc., New York.

Peripheral injury enhances central regeneration of primary sensory neurones

P. M. Richardson & V. M. K. Issa

Division of Neurosurgery, Montreal General Hospital & McGill University, 1650 Cedar Avenue, Montreal, Canada H3G 1A4

The success of peripheral and fetal neural tissue in promoting outgrowth of axons from the adult mammalian central nervous system[1–4] has tended to focus attention on local interactions between extending axons and their environment. The contribution to axon regeneration of biochemical and morphological changes in injured neurones[5–7] is more difficult to evaluate. We report here that long spinal axons of primary sensory neurones are 100 times more likely to regenerate into peripheral nerve grafts if their peripheral axons are also cut. Regenerative behaviour at the axon tip seems to be strongly influenced by inducible events in the nerve cell.

In each of 11 rats, 6–8 weeks old, the dorsal columns were incised bilaterally after high cervical laminectomy and a segment from the right sciatic nerve was transplanted in the midline to the injured spinal cord. Such autogenous grafts provide a favourable milieu for spinal axons that usually fail to regenerate in their natural neuroglial environment[2,8,9]. Two to three months after the operation, retrograde tracing with horseradish peroxidase (HRP) was used to identify neurones with axons regenerating from the spinal cord (Fig. 1). Particular attention was paid to the L4 and L5 dorsal root ganglia (DRG), which contain many large neurones projecting centrally to the brain stem and peripherally to the sciatic nerve. Control experiments with crushing of grafts near the spinal cord at the time of injection of HRP excluded the possibility of false-positive labelling by diffusion or vascular spread. It was assumed that a neurone was labelled only if its spinal axon had entered a peripheral nerve graft and grown several millimetres or more within it. On the left, the L4 and L5 DRG usually contained no labelled neurones, and the most per pair was 10. On the right, all L4 or L5 DRG contained labelled neurones and the maximum for a pair of ganglia was 682. In all 22 matches between L4 or L5 ganglia the count was always higher on the right than on the left. The mean count per ganglion on the right (114) was more than 100-fold greater than on the left (<1). To provide a rough estimate of the size of the pool of lumbar sensory neurones with axons projecting to the vicinity of the dorsal column nuclei, a mixture of wheat germ agglutinin and HRP was injected into the dorsal columns at high cervical level in normal rats. The highest number of labelled neurones counted in a single L5 DRG was 840. In DRG of some grafted animals, the number of neurones with regenerating spinal axons exceeded 50% of this count.

Similar grafting and labelling techniques were used on four other groups of rats (Fig. 2*a*) receiving different combinations of treatments to the two sciatic nerves. When neither sciatic nerve was cut (in Lewis rats with isogenous grafts), almost no regeneration was detected from lumbar DRG; when both sciatic nerves were cut, the mean count for labelled neurones in L4 + L5 DRG on each side was 385 and the difference between counts on the two sides was not significant. The latter result excludes a systematic bias in positioning of the grafts or a strong tendency for axons in one dorsal column to regenerate into an ipsilateral rather than contralateral nerve segment. Sham operation or crushing of the sciatic nerve was much less effective than nerve transection in evoking spinal regeneration; after either procedure, counts of labelled neurones in ganglia on the appropriate side averaged less than 10% of those on the side from which the graft was taken. In 70 C8 DRG, the mean and range of the number of labelled neurones were 1 and 0–7, respectively. Sciatic nerve injury did not seem to influence growth into grafts of axons arising from contralateral lumbar DRG or cervical DRG.

Finally, injuries to peripheral and spinal axons were staggered in time by grafting a segment of one sciatic nerve to the spinal cord and cutting the other sciatic nerve 1 or 4 weeks earlier or later (Fig. 2*b*). Sciatic nerve injury was comparably effective in inducing central regeneration when it preceded rather than coincided with grafting. However, after a delay of as little as 1 week, cutting the second sciatic nerve resulted in significantly less regeneration from the corresponding dorsal column. It appeared that a propensity for regeneration persisted in sensory neurones for at least 1 month after sciatic nerve transection but that the environment near the junction between spinal cord and nerve segment became less conducive to axon outgrowth within 1 week of grafting.

After injury at high cervical level, spinal axons of neurones with cell bodies in L4 and L5 ganglia regenerated in abundance only if the ipsilateral sciatic nerve was also cut. The virtual absence of regeneration in basal conditions indicates that normal cellular function in these nerve cells does not usually support regeneration of their spinal axons injured at a distance from their somata. The enhancement of regeneration by a stimulus remote from the site of axon growth suggests that critical cellular responses affecting the entire neurone have been induced. Under other circumstances, events in these perikarya are of questionable significance during axon regeneration; for example, axons in crushed dorsal roots regrow towards the spinal cord with no obvious chromatolysis or change in axoplasmic transport[10–12]. The neuronal reactions[6,13,14] that promote regeneration of spinal axons, and the retrograde signals[15–17] that trigger these cellular responses are unknown.

Priming of peripheral nerve regeneration by a preceding crush injury[18] differs from the enhancement seen here in that conditioning and testing lesions are separated temporally rather than spatially. A 'pruning' effect that has been described after a single lesion to branching axons of invertebrates and vertebrates[19–21] involves proliferation of uninjured fibres as

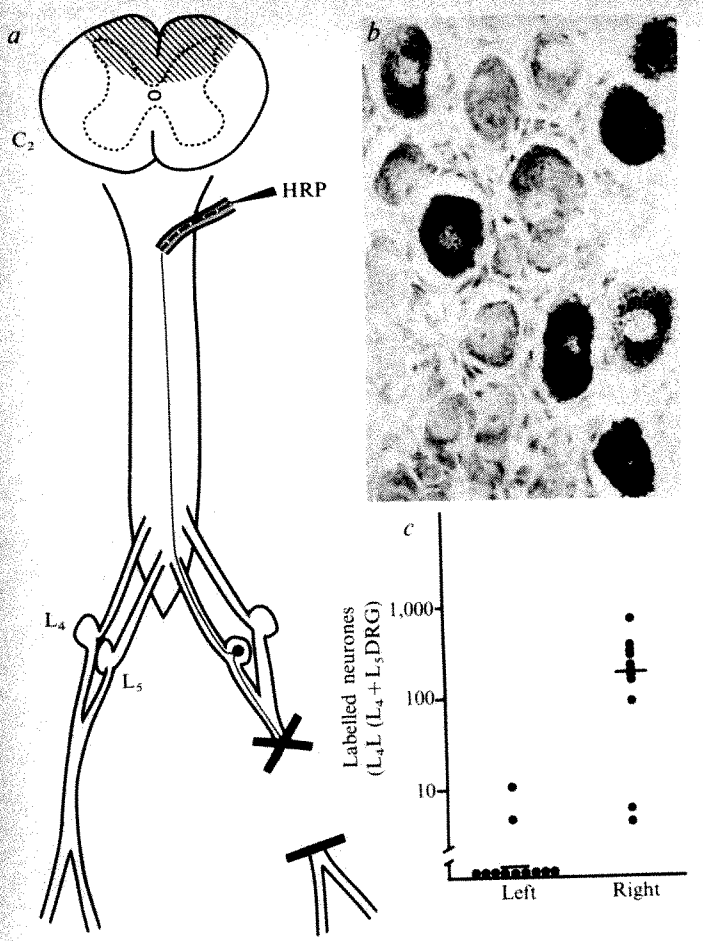

Fig. 1 *a*, Diagram showing experimental procedure. Experiments were performed on female rats weighing ~150 g and anaesthetized with pentobarbital. Under an operating microscope, the second cervical lamina was removed and a symmetrical transverse incision approximately 1 mm deep was made in the dorsal columns. One end of a 2-cm segment of the right sciatic nerve was apposed to the injured spinal cord in the midline with a stitch through the meninges. The left sciatic nerve was uninjured. Two to three months after grafting, the other end of each graft was exposed subcutaneously in the suboccipital region and injected with a total of 1 μl 20% HRP through a glass micropipette. Two days later the rats were perfused with buffered 3% glutaraldehyde and serial sections, 20 μm thick, were cut through the L4 and L5 DRG, reacted with tetramethylbenzidine[29] and counterstained with neutral red. *b*, Representative HRP-containing neurones in an L4 DRG on the right side. *c*, Labelled neurones were counted in the L4 and L5 DRG of 11 rats. To avoid double counting, only neurones with visible nucleoli were counted. The error due to split nucleoli was ignored. The difference between numbers of labelled neurones in DRG on the left and right was highly significant ($P < 0.001$) to either Mann–Whitney or Student's *t* statistical testing. Bars represent mean sums of labelled neurones in L4 and L5 DRG.

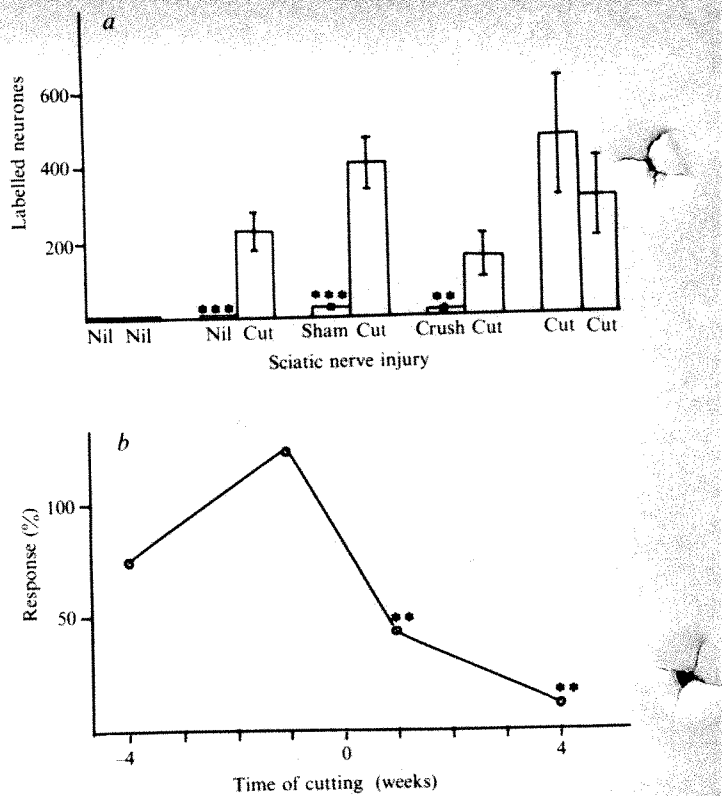

Fig. 2 *a*, Sums of labelled neurones in the L4 and L5 DRG recorded for left and right sides in five groups of rats. Nil, no operation on leg; sham, sciatic nerve exposed but not cut; cut, sciatic nerve cut at the origin of the nerve to the biceps; crush, sciatic nerve crushed for 15 s with jeweller's forceps at the level of the nerve to the biceps. Means ± s.e.m., $n = 6$–11. Asterisks indicate significantly fewer neurones than on the cut side: ** $P < 0.01$, *** $P < 0.001$ (Mann–Whitney *U*-test). *b*, In four groups of rats ($n = 6$–9), the left sciatic nerve was cut 1 or 4 weeks before or after grafting of a segment of the right sciatic nerve to the dorsal spinal cord at high cervical level. For each point, the sum of labelled neurones on the left is expressed as a percentage of the sum on the right for the entire group. ** Significant difference between the two sides ($P < 0.01$, Mann–Whitney *U*-test).

opposed to regeneration of cut axons. Possibly, all three phenomena reflect similar molecular events. Other transganglionic effects of peripheral axotomy on central axons of mammalian sensory neurones include changes in fibre diameter, conduction velocity, fast axoplasmic transport and content of peptides and enzymes[14,22–26]. Reasons for the difference between the effects of peripheral nerve crush and transection on the function of sensory neurones[5,23,27,28] are unclear.

Without peripheral axotomy, spinal axons of primary sensory neurones regenerate into peripheral nerve grafts no better than, for example, rubrospinal or spinocerebellar axons[9]. Very few axons from dorsal or lateral spinal tracts grow into peripheral nerve segments after injury more than a few centimetres from their cell bodies. When sensory neurones are stimulated by peripheral nerve transection, their spinal axons regenerate much more vigorously than without a second injury. The hypothesis that neurones lying entirely within the central nervous system might be extrinsically induced in a similar manner is exciting to contemplate but difficult to test.

Vitamin E protects against retinopathy of prematurity through action on spindle cells

Frank L. Kretzer*, Rekha S. Mehta*, A. Tim Johnson†, David G. Hunter‡, Evelyn S. Brown* & Helen M. Hittner§

* Cullen Eye Institute, † Program in Neuroscience and Departments of ‡ Cell Biology and § Pediatrics, Baylor College of Medicine, Houston, Texas 77030, USA

In the premature infant, exposure of the incompletely vascularized retina to increased oxygen tension can result in the development of a blinding disease, retinopathy of prematurity (ROP). Despite the judicious curtailment of oxygen, the incidence of ROP is on the increase due to the technological advances that have improved the survival of the very young preterm infant[1]. Six clinical trials[2–7] have documented the efficacy of vitamin E supplementation in suppressing the development of severe ROP[8–10], but the mechanism of this protection has remained unknown. This report proposes that spindle cells, mesenchymal precursors of the inner retinal capillaries, are the primary inducers of the neovascularization associated with ROP. Exposure of spindle cells to elevated oxygen tension increases their gap junction area. This early morphologic event immediately halts the normal vasoformative process and eventually triggers the neovascularization that is observed clinically 8–12 weeks later. Vitamin E supplementation above the deficient plasma levels of these infants[11] suppresses gap junction formation and clinically reduces the severity without altering the total incidence of ROP.

The database is 69 pairs of whole-eye donations from infants who were live-born, anomaly-free at 20 to 31 weeks gestational age and ≤1500 g birth weight, and who survived from 30 min to 20 weeks. Twenty-two infants received minimal or no vitamin E supplementation (control infants) with mean plasma vitamin E levels of 0.3–0.6 mg%; 47 infants received vitamin E supplementation (treatment infants) with mean plasma vitamin E levels of 1.2–3.3 mg%, which are within the adult physiologic range[12,13]. All whole eye donations contained avascular regions in all quadrants of the retina and were processed for light[14], transmission[15], and scanning electron microscopy. Light micrographs of continuous areas from the optic disk to the ora serrata of both the nasal and temporal hemispheres were assembled into montages. Along these montages, the following parameters were determined morphometrically: percentage of vessels with necrotic endothelial cells, percentage of spindle cells in a migrating or canalizing configuration, and percentage volume of the nerve fibre layer occupied by spindle cells[14]. Gap junction surface area between adjacent spindle cells was calculated from 40,000X electron micrographs using a Zeiss Videoplan and expressed as the percentage of the spindle plasma membrane surface area that was differentiated into gap junctions. All P values were calculated from a paired Student's t-test. All data are given for only the temporal hemisphere.

The morphometric analyses allow the role of the spindle cells in retinal vasoformation to be elucidated. As retinal development (Fig. 1*a*) and stratification (Fig. 1*b*) proceed peripherally from the optic disk, an apron of interdigitating spindle cells emerges from the adventitia of the hyaloid artery and migrates behind an advancing point of retinal development (Fig. 1*c*). The fusiform spindle cells within the migrating apron (Fig. 2*a*) are randomly oriented within the plane of the nerve fibre layer (Fig. 2*b*). Central to the fringe of the migrating arpon, nascent retinal blood vessels are formed by canalization of spindle cells (Fig. 2*c*). The canalization process involves formation of a lumen within a solid cord of spindle cells. Eventually erythrocytes from the formed capillaries penetrate the lumen (Fig. 2*d*). This entire sequence of migration, canalization, and endothelial differentiation normally occurs in the hypoxic (P_{O_2} = 25 mmHg)[16] *in utero* environment.

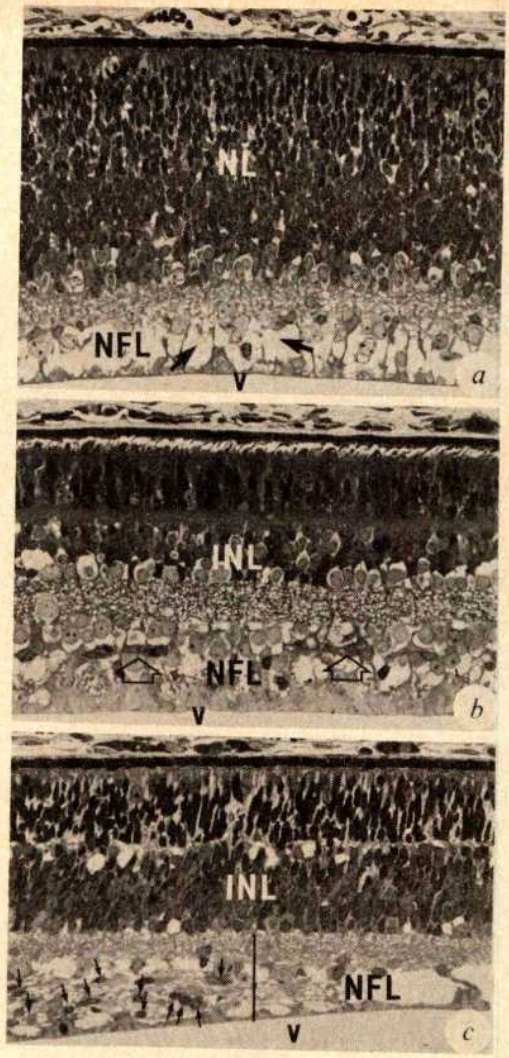

Fig. 1 Light micrographs (×240) demonstrating the relationship between the state of retinal development and the invasion of spindle cells into the nerve fibre layer. *a*, Undifferentiated midperipheral retina with primitive outer neuroblastic layer (NL) and no spindle cells within the nerve fibre layer (NFL) which is laced with cystoid spaces (→). *b*, Differentiated central retina in which the nerve fibre layer (NFL) contains developing capillaries (⌓). *c*, Apron of spindle cells (⇉) within the nerve fibre layer (NFL). The migration ceases at a distinct point (—) of retinal development. Inner nuclear layer (INL), vitreous (V).

The gap junction area of the spindle cells (Fig. 3) is modulated by oxygen tension, vitamin E supplementation, and gestational age. For the first four days post partum (14 control and 13 treatment infants), the the average gap junction area remains low (4.6 ± 2.1, range <1–12.1) (Figs 3*a*, 4), with spindle cells occupying <16% of the nerve fibre layer volume. These spindle cells are in migrating and canalizing configurations. In the absence of vitamin E supplementation (8 control infants), there is a significant (P = 0.0005) increase in gap junction area (Fig. 3*b*) as early as four days post partum (Fig. 4*a*). There is a cessation of canalization, and severe ROP develops in this group around 9 weeks post partum[5–7]. Despite the increase in gap junction area, the spindle cells still occupy <13% of the nerve fibre layer volume until after the development of severe ROP. The down modulation of gap junction area (>70 days post partum) (Fig. 4*a*) is a late event that correlates with stacking

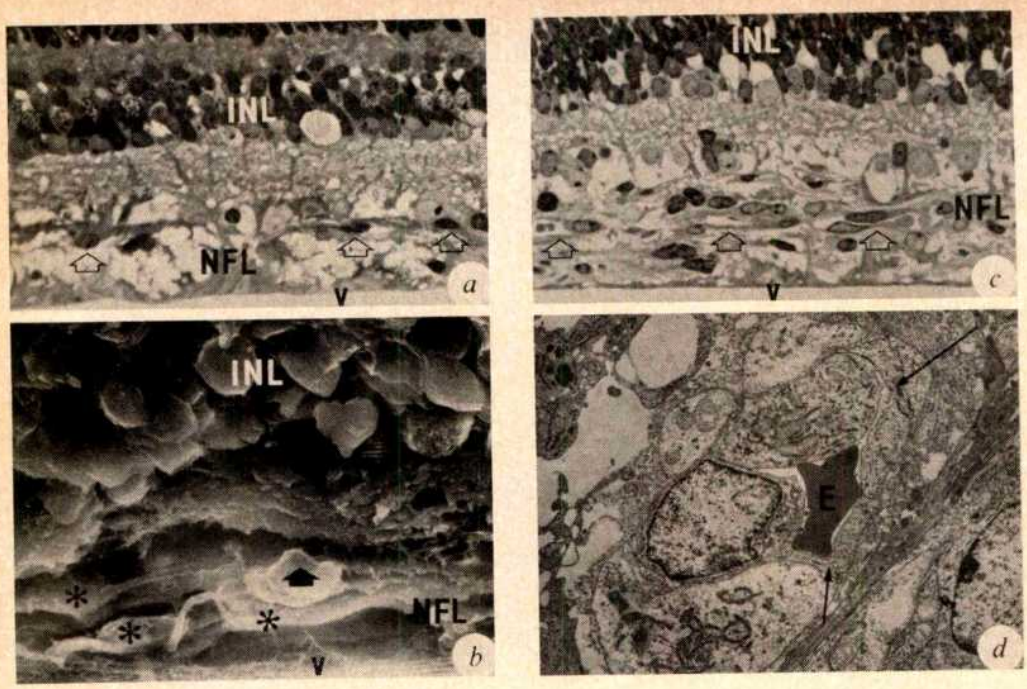

Fig. 2 Migrating and canalizing spindle cells within the developing human retina. *a*, Light micrograph (×435) of migrating spindle cells (⌓) forming an anastomising apron within the nerve fibre layer (NFL). *b*, Scanning electron micrograph (×2,250) of the migrating, fusiform spindle cells which are randomly oriented within the plane of the NFL. Contrast those spindle cells lying in a plane parallel to the scanned surface (✳) with those at right angles (◆). Inner nuclear layer (INL), vitreous (V). *c*, Light micrograph (×750) of canalizing spindle cells (⌓) posterior to the advancing apron in the NFL. *d*, Electron micrograph (×3,750) of canalizing spindle cells with erythrocyte (E) penetration into the lumen and marginal flap formation (←).

of the spindle cells such that they occupy 30–54% of the nerve fibre layer volume. Vitamin E supplementation suppresses gap junction formation, but this suppression is strongly dependent upon gestational age. In treatment infants ≤27 weeks (18 infants) (Fig. 4*b*), there is a lag period of approximately 16 days post partum in which minimal increases in gap junctions occur. Following this lag, there is a rapid increase in gap junction area to a level equivalent ($P = 0.3$) to that of unsupplemented infants. There is a parallel cessation of spindle cell canalization, but development of severe ROP in this group is delayed to around 12 weeks post partum[5–7]. In all treatment infants shown in Fig. 4*b*, the spindle cells occupy <14% of the nerve fibre layer volume. In treatment infants ≥28 weeks gestational age (Fig. 4*c*) (16 infants), gap junction formation is suppressed, canalization of spindle cells continues, spindle cells occupy a minimal volume of the nerve fibre layer (<13%), and no severe ROP develops. Thus, while continuous supplementation in infants ≥28 weeks gestational age suppresses gap junction formation and the development of severe ROP, supplementation in infants ≤27 weeks gestational age delays the onset of gap junction formation but does not diminish the severity of ROP in the highest risk infants. Vitamin E supplementation delays the down modulation of gap junction area and the clinical development of severe ROP (Fig. 4*a*, *b*).

Based on these ultrastructural observations, the following mechanism of the induction and suppression of ROP is proposed. When the retinas of high risk premature infants are exposed to relative hyperoxia, the elevated oxygen tension induces the formation of gap junctions between adjacent spindle cells. The gap junctions are the first morphologic evidence of oxygen toxicity, and their formation results in the subclinical cessation of spindle cell migration and canalization. The ionic coupling of spindle cells via gap junction formation changes the cells from potential endothelial precursors to sites of synthesis and release of angiogenic factors. The angiogenic factors trigger neovascularization from existing vessels over the next 8–12 weeks. Vitamin E supplementation to adult physiologic levels (1.1–3.3 mg%) suppresses gap junction formation by protecting the spindle cells from oxygen related damage, and thus reduces the severity of ROP.

This proposed mechanism of ROP induction can explain four clinical realities regarding the development, suppression, and treatment of this disease: (1) The clinical observation that

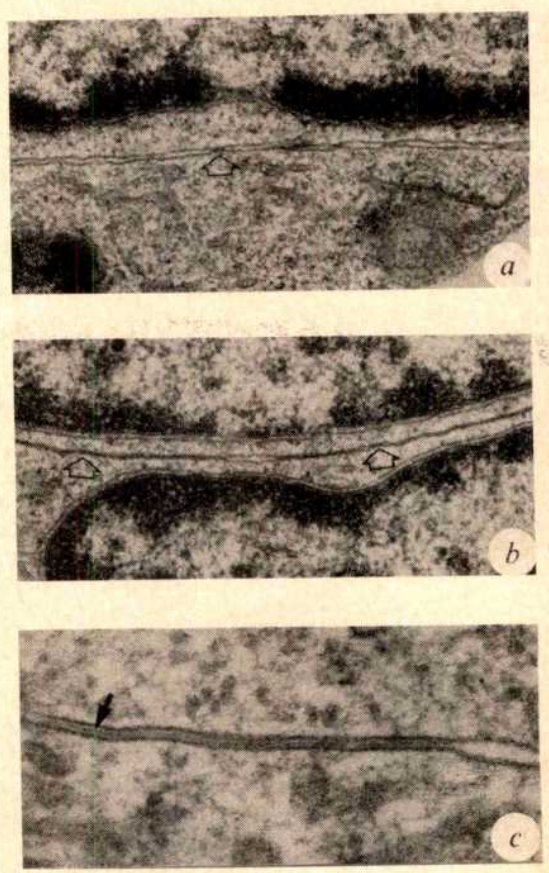

Fig. 3 Gap junctions between adjacent spindle cells. *a*, *b* Are electron micrographs (×32,000) demonstrating the plasma membrane surface area changes. *a*, Punctate close plasma membrane appositions (⌓); such spindle cells are actively migrating and canalizing. *b*, Extensive close plasma membrane appositions (⌓); such spindle cells have ceased migrating and canalizing and are primed to induce neovascularization from nascent capillaries. *c*, At higher magnification (×110,000), the close plasma membrane appositions are resolved as gap junctions with substructure within the 20–30 Å gap (→).

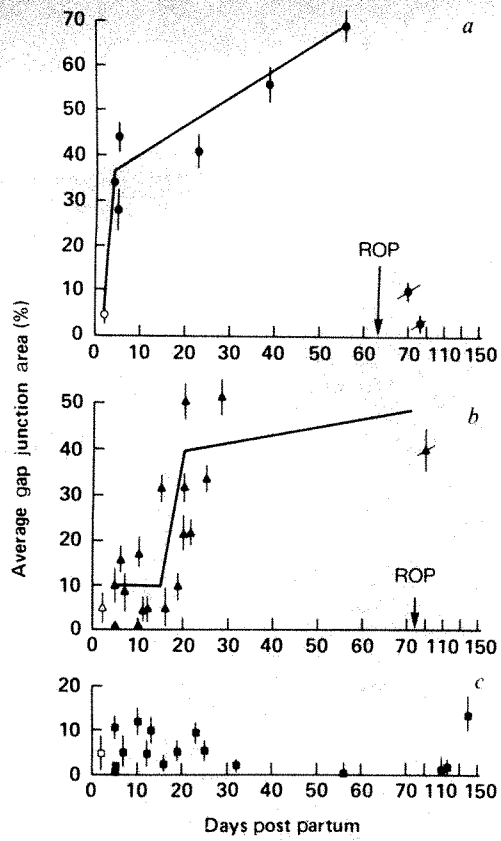

Fig. 4 Average gap junction area (%) ± s.e.m. as a function of days post partum. *a*, Control infants, $n = 8$ (●). *b*, Treatment infants ≤27 weeks gestational age, $n = 18$ (▲). *c*, Treatment infants ≥28 weeks gestational age, $n = 16$ (■). For each group, the average gap junction area in equivalent infants who survived for <4 days post partum (○, 14 infants; △, 9 infants; and □, 4 infants) is plotted. The three infants with clinically documented severe ROP are represented by ●, and ▲. The time when severe ROP develops for each group (arrows in *a*, *b*) is based on the results of clinical studies which enrolled 418 high risk preterm infants[5–7].

vitamin E supplementation is not efficacious unless initiated at birth[4–10] is explained by the ultrastructural observation that gap junctions can increase as early as four days post partum; thus, antioxidant protection is needed concomitantly with the increase in oxygen tension. (2) Although vitamin E supplementation suppresses gap junction increases in infants ≥28 weeks gestational age, it is not an absolute suppression; thus, the severe blinding grades of ROP are suppressed[5–7] while the total incidence of all grades of ROP remains constant. (3) Severe ROP may develop in infants ≤27 weeks gestational age despite continuous supplementation because vitamin E only transiently suppresses increases in gap junctions in these infants. After a lag period of approximately 2 weeks, gap junctions may increase to a level commensurate with that of unsupplemented controls. This lag correlates with the delayed onset of severe ROP in the highest risk infants[5–10]. (4) Ablation of only the avascular peripheral retina has been utilized empirically to induce regression of severe ROP before retinal detachment[17–19]. The proposed mechanism of ROP induction would predict the success of this procedure, since it involves the destruction of the gap-junction-linked spindle cells. In contrast, ablation of the proliferating vessels or the vascular:avascular interface leads to vitreous haemorrhage and retinal separation[20–22]. The ultrastructural explanation of the failure of this procedure is that the gap-junction-linked spindle cells remain operant and continue to secrete angiogenic factors and induce neovascularization.

The spindle cell mechanism for the induction of ROP contrasts with that proposed by Ashton[23] and Patz[24,25] in which vasoconstriction, vaso-obliteration, endothelial necrosis, and hypoxia were believed to be the initiating events. No endothelial cell necrosis was observed in any of the 69 pairs of whole eye donations in this study. Only the spindle cell concept explains the natural history of ROP and the gestational age dependence of the efficacy of vitamin E supplementation in suppressing the development of severe ROP. Furthermore, it rationalizes surgical intervention that destroys the peripheral inducers of this developmental retinopathy.

Correlation between inositol phospholipid hydrolysis and substance P receptors in rat CNS

P. W. Mantyh, R. D. Pinnock, C. P. Downes*, M. Goedert & S. P. Hunt

MRC Neurochemical Pharmacology Unit, Medical Research Council Centre, Medical School, Hills Road, Cambridge CB2 2QH, UK

The undecapeptide substance P is a neurotransmitter candidate in the mammalian central and peripheral nervous system[1]. Although the distribution of substance P-like immunoreactivity within the central nervous system (CNS) is well established[2], the recent identification and autoradiographic localization of specific substance P-binding sites has revealed numerous areas of mismatch between peptide levels and numbers of such sites[3–6]. Previous studies have shown that substance P stimulates the hydrolysis of inositol phospholipids in peripheral tissues and in the hypothalamus[7,8], probably through stimulation of a polyphosphoinositide-specific phospholipase C (refs 9–11). Inositol phospholipid hydrolysis has been implicated in the mobilization of cytosolic calcium following receptor activation in several neurotransmitter and hormonal systems[12]. We have therefore investigated the distribution of ^{3}H-labelled substance P binding sites within various rat brain regions and correlated this with the rate of substance P-induced hydrolysis of inositol phospholipids in the same areas of the CNS. We found that the rate of inositol phospholipid hydrolysis was proportional to the number of binding sites specific for ^{3}H-substance P, suggesting that binding sites revealed by ^{3}H-substance P autoradiography correspond to functional substance P receptors.

* Present address: Imperial Chemical Industries plc, Pharmaceutical Division, Mereside, Alderley Park, Macclesfield, Cheshire SK10 4TG, UK.

The distribution of specific ^{3}H-substance P-binding sites throughout the rat brain was initially determined. Adult male Sprague–Dawley rats were killed, their brains removed, frozen on dry-ice and 20-μm sections cut using a cryostat in either the horizontal or the coronal plane. They were apposed onto gelatinized glass slides and stored in boxes with desiccant for 48 h at −20 °C. The sections were then preincubated at room temperature for 10 min in a solution containing 0.005% polyethyleneimine in 50 mM Tris-HCl, *p*H 7.40, followed by incubation in the presence of ^{3}H-substance P. Nonspecific binding was

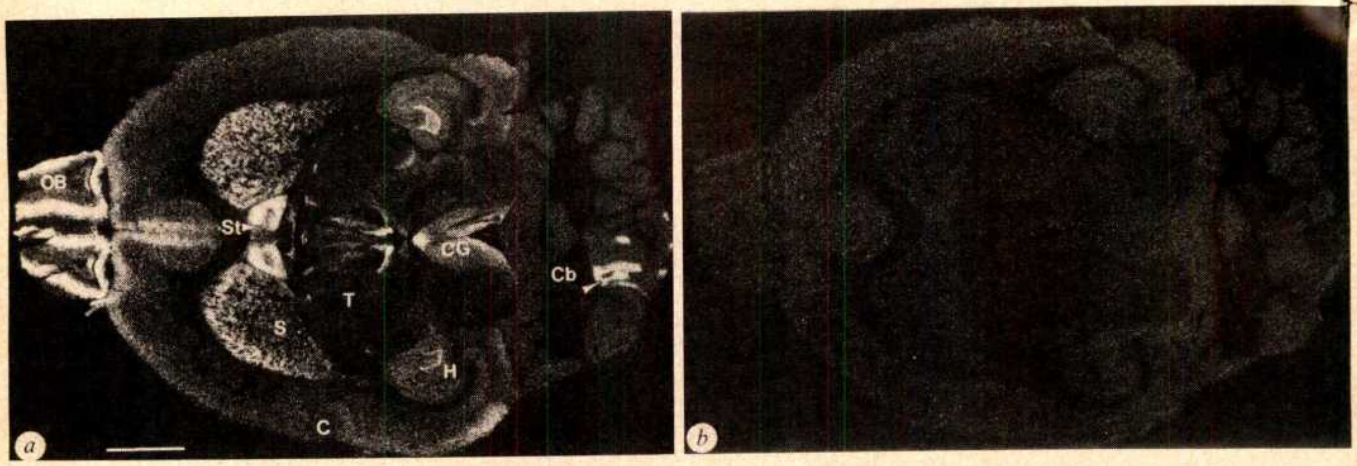

Fig. 1 ^{3}H-substance P-receptor distribution in the rat brain. *a*, A typical darkfield photomicrograph of ^{3}H-substance P binding in a horizontal brain section. The light areas are silver grain concentrations indicative of specific binding. *b*, A darkfield photomicrograph of an adjacent control section treated identically to *a*, except that 1 μM substance P (Peninsula) was added to the incubation solution. Note the heavy labelling in several areas, such as the external plexiform layer of the olfactory bulb (OB), the striatum (S), the septum (St), the central grey (CG) of the midbrain and folia IX and X of the cerebellum (Cb, arrowhead), moderate labelling in the cortex (C) and hippocampus (H) and absence of label in the thalamus (T). Scale bar, 2.5 mm.

Methods: Horizontal 20-μm sections were preincubated at room temperature for 10 min in a solution of 50 mM Tris-HCl (*p*H 7.4) containing 0.005% polyethyleneimine (Sigma). The slides were then incubated for 10 min in a solution of 50 mM Tris-HCl (*p*H 7.4) containing 0.02% bovine serum albumin (Sigma, radioimmunoassay grade), chymostatin (2 mg l^{-1}; Sigma), leupeptin (4 mg l^{-1}; Sigma), bacitracin (40 mg l^{-1}; Sigma) and increasing concentrations of [2-L-prolyl-3,4-^{3}H(*N*)] substance P (specific activity 26 Ci $mmol^{-1}$, NEN). Nonspecific binding was defined as binding in the presence of 1 μM substance P (Peninsula) and specific binding obtained by subtracting the nonspecific binding from the total binding. In these incubation conditions >95% of ^{3}H-substance P eluted at the position of intact substance P on reverse-phase HPLC and the specific binding reached a plateau after about 8 min. The slides were rinsed with four washes of ice-cold 50 mM Tris-HCl (*p*H 7.4), 5 s each, and four washes of water, 5 s each, dried in a stream of cold air and stored overnight in desiccant. The slides were then placed in apposition to a tritium-sensitive film (^{3}H-Ultrofilm, LKB). After 12 weeks the film was developed using Kodak D-19 developer and photographed under darkfield illumination. To estimate the relative density of specific ^{3}H-substance P-binding sites we used microdensitometry combined with the tritium-sensitive film, as described previously[14]. The exposed film was placed on the stage of a Leitz orthoplan microscope equipped with a Vario-Orthomat camera system. Direct reading of the voltage from the photosensitive cell served as a density reading. Calibration experiments were used to determine in which region the density was linearly dependent on the isotope concentration and the measurements were performed in that region. The densitometer was able to resolve density differences of the orderof 0.02 *A* units and readings were taken from an area of 200 μm diameter. Background labelling was defined as the ^{3}H-substance P binding in the presence of 1 μM substance P.

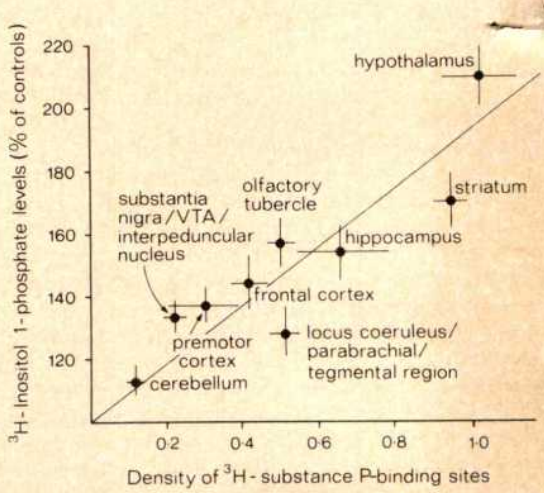

Fig. 2 The density of substance P receptors plotted against the magnitude of substance P-induced inositol phospholipid hydrolysis in various regions of the rat brain. The density of substance P receptors was determined using autoradiography coupled to a tritium-sensitive film and analysed using microdensitometry, as described for Fig. 1. All readings were taken from sections incubated in and exposed to the same conditions. To quantify the relative density of receptors, we designated the highest area measured (the hypothalamus) as 1.0 and ranked the others accordingly. The mean ± s.e.m. of at least four determinations throughout the area under examination was taken.

Methods: The substance P-induced hydrolysis of inositol phospholipids in various regions of the rat central nervous system was determined according to Berridge *et al.*[15]. Sprague–Dawley rats (150–200 g) were killed, the brain removed, blocked and placed into an oxygenated solution of artificial cerebrospinal fluid (CSF, composition in mM: NaCl, 124; KCl, 2; KH_2PO_4, 1.25; $MgSO_4$, 2; $CaCl_2$, 2; $NaHCO_3$, 25 and glucose, 11). Sections (300 μm) were cut using a vibratome (Oxford Instruments) and the appropriate brain area dissected out using microscissors; one side was used for stimulation with substance P and the contralateral side served as the control. Sections were placed in CSF solution for 2 h at 37 °C and then transferred to 500 μl of prewarmed oxygenated CSF to which 1 μCi myo-[2-^{3}H]inositol (specific activity 10–20 Ci $mmol^{-1}$) (Amersham) and 12 mM LiCl had been added. One hour later 1 μM substance P (Peninsula) was added and the tubes were incubated for another 30 min. The incubation was terminated by addition of 500 μl trichloroacetic acid and the tubes were left for 15 min on ice. Following a 15-min centrifugation at 2,000*g*, 700 μl of the supernatant was removed. The latter was then washed three times with 4 ml of ether, with the ether phase being discarded after each wash, and 700 μl of 20 mM Tris-HCl containing 5 mM EDTA was added to each tube. Tritiated inositol 1-phosphate was separated from other water-soluble metabolites by application of the sample to columns containing 1 ml of Dowex 1-X8 (Sigma) in the formate form. The columns were washed twice with 8 ml of 60 mM ammonium formate/5 mM disodium tetraborate and ^{3}H-inositol 1-phosphate was eluted with 8 ml of 200 mM ammonium formate/100 mM formic acid and the radioactivity determined by liquid scintillation spectrometry. The levels of ^{3}H-inositol 1-phosphate are expressed as per cent of controls (taken as 100). In a typical experiment on the hypothalamus the control value was 1,844 ± 127 d.p.m. ^{3}H-inositol 1-phosphate per tissue slice ($n = 6$). The results are expressed as the means ± s.e.m. of triplicate determinations from four separate experiments.

defined in the presence of 1 μM substance P. Preliminary experiments had shown that, in the absence of polyethyleneimine, >95% of the ^{3}H-substance P binding was to the glass around the tissue rather than to the tissue itself, while specific binding reproducibly amounted to 60% of the total binding in the presence of polyethyleneimine. Following incubation in the presence of ^{3}H-substance P, tissue sections were apposed to a tritium-sensitive film.

Previous experiments[13] had shown that ^{3}H-substance P bound to a single class of binding sites with an equilibrium dissociation constant of 1.1 nM and a maximum number of binding sites of 15 fmol per mg tissue. The fragment potencies agreed well with results from studies on the CNS which had used tissue homogenate binding assays for substance P[4,5].

The correlation between the autoradiographic distribution of specific ^{3}H-substance P-binding sites (Fig. 1) and a biochemical response linked to substance P-receptor occupancy was investigated by incubating vibratome sections from various brain regions in the presence of 1 μM substance P and measuring the rate of inositol phospholipid hydrolysis. When the magnitude of substance P-stimulated inositol phospholipid hydrolysis was plotted against the mean number of specific substance P-binding sites in various brain regions, an excellent correlation was obtained (correlation coefficient 0.96, as judged by regression analysis; Fig. 2).

The present results therefore indicate that, while the distribution of substance P receptors in the CNS does not correlate with the distribution of substance P-like immunoreactivity[3–6], the increase in inositol phospholipid hydrolysis effected by substance P is directly proportional to the number of specific ^{3}H-substance P-binding sites present in various brain regions. Given the interest in substance P agonists and antagonists, this measure of inositol phospholipid hydrolysis should provide a reliable biochemical assay for substance P receptors in the CNS.

H–2-linked low-molecular weight polypeptide antigens assemble into an unusual macromolecular complex

John J. Monaco & Hugh O. McDevitt

Department of Medical Microbiology, Stanford University School of Medicine, Stanford, California 94305, USA

The major histocompatibility complex (MHC) is a cluster of tightly linked genes whose products are of central importance in the functioning of the immune system. Class I and II MHC antigens are integral membrane proteins which regulate cell-surface interactions between T cells and their targets[1–3], while class III antigens are components of the complement system of serum proteins[4]. All available evidence indicates that the structure and function of the MHC and its gene products are highly conserved among species (for review, see ref. 5). We recently reported[6] the existence in murine cells of a fourth class of MHC-linked polypeptides which are biochemically and genetically distinct from previously identified MHC gene products: BALB.B anti-BALB/c (anti-H–2^d) antiserum immunoprecipitates a set of 16 cytoplasmic low-molecular weight polypeptides (LMP) from BALB/c spleen cells and from the WEHI-3 cell line. The production of these peptides is coordinately regulated (by immune interferon) with the production of the class I and II MHC antigens[7,8], suggesting that they too are functionally relevant to the immune system. We demonstrate here that these 16 polypeptides are associated with one another *in vivo* as a very large (580,000-molecular weight, M_r) noncovalent complex. The unusual nature of this complex has allowed the non-immunochemical identification of similar complexes from (serologically negative) H–2^b murine cells and from a human cell line. Thus, LMP antigens display two properties in common with other MHC antigens: they are both polymorphic and genetically conserved across species.

To determine whether our antiserum recognizes 16 different chains, or whether some of the LMP are associated with one another *in vivo*, extracts of ^{35}S-methionine-labelled WEHI-3 cells were size-fractionated by gel filtration before immunoprecipitation. As Fig. 1 shows, all of the LMP activity elutes from the column as a single peak of ~580,000 M_r. No LMP activity is detectable in the lower molecular weight column fractions. This peak of LMP activity is clearly distinct from the void volume peak (Fig. 1) which, in the absence of detergent, contains all of the (aggregated) H–2 and Ia antigens present in the original sample (data not shown), and presumably any other nonspecifically aggregated material. More importantly, the LMP peak is bounded on both sides by molecular weight markers. The results of gel filtration using gels of different exclusion limits and with different buffers (Table 1) were always consistent with the data shown in Fig. 1. This experiment therefore strongly suggests that all 16 LMP polypeptides are specifically associated with one another *in vivo* in the form of a high-molecular weight complex.

Figure 2*b*, *c* compares the peak LMP fraction from the gel filtration column with an LMP immunoprecipitate, and shows that nearly all of the peptides found on the portion of the gel shown ($M_r \simeq 12{,}000$–$35{,}000$) in Fig. 2*c* are LMP chains. Note, however, that there is a large amount of labelled material in the higher molecular weight portion ($M_r > 50{,}000$; not shown) of the gel in Fig. 2*c* which does not appear in LMP immunoprecipitates and is therefore not part of the LMP complex. In fact, the purity of the peak chromatography fraction can be roughly estimated by comparing the total number of ^{35}S c.p.m. in the fraction with the number of c.p.m. in the LMP chains (determined by immunoprecipitation). By this criterion, the LMP comprise only approximately 1–2% of the total material in the fraction.

Thus, a single step of gel filtration yields a sample of LMP which is sufficiently pure to be visualized cleanly by two-dimensional polyacrylamide gel electrophoresis (PAGE) without prior immunoprecipitation. We have also used this technique to analyse the remaining column fractions in Fig. 1 (data not shown). No LMP chains are detectable in any of the fractions except that corresponding to the LMP peak shown, indicating that the individual LMP chains do not exist in an uncomplexed form. In addition, for all of the fractions in which LMP chains are detectable, the relative intensity of the individual chains seems to be constant. These experiments therefore suggest

Table 1 Gel filtration of LMP complexes in various conditions

Sephacryl S200	TBS + 0.5% NP40	>250,000*
Sephacryl S200	DPBS	>250,000*

* All LMP activity was present in the column void volume peak.

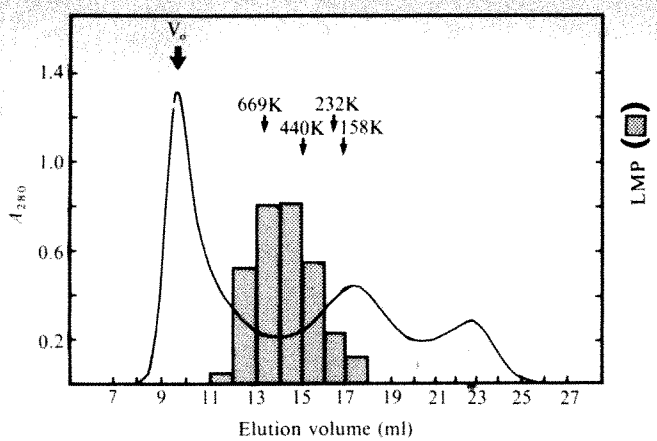

Fig. 1 Immunoprecipitation of LMP antigens from size-fractionated WEHI-3 extracts. Cells were grown and labelled with ^{35}S-methionine as described previously[6]. Before labelling, cells were grown for 2–4 days in the presence of concanavalin A-activated spleen cell supernatants to induce maximal LMP expression (see ref. 8). For gel filtration experiments, the washed labelled cells were resuspended in Dulbecco's phosphate-buffered saline (Gibco) containing 0.1% sodium azide (DPBS) and lysed by five cycles of freeze/thaw. Membranes and insoluble cellular debris were pelleted by centrifugation, and the clear supernatants were stored at −70 °C until use. A 0.5 × 30 cm Sepharose CL-6B column calibrated with molecular weight standards (Pharmacia) was used. Arrows designate the elution volume of molecular weight markers: V_0, void volume; 669,000 (669K), thyroglobulin; 440K, ferritin; 232K, catalase; 158K, aldolase. Samples (0.5 ml) were run in DPBS or DPBS containing 0.5 M NaCl, and 1-ml fractions were collected. Immunoprecipitations were performed on column fractions as described previously[6], except that 500 μl of sample and 50 μl of antiserum were used. For samples to be analysed without immunoprecipitation, 10 μl of sample were mixed with 10 mg of urea and 10 μl of isoelectric focusing sample buffer; 20 μl of this mixture were loaded onto the gel. Two-dimensional PAGE was performed as described previously[6]. The amount of LMP antigens was measured by densitometry of the resulting autoradiographs, and is reported in arbitrary units.

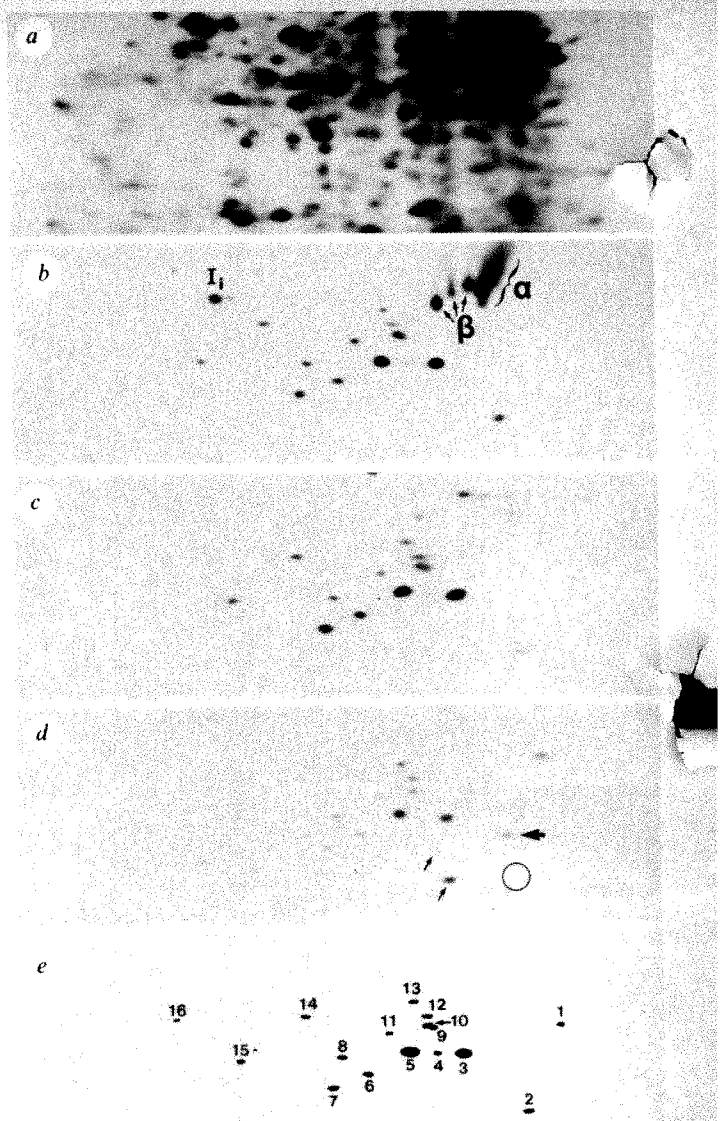

Fig. 2 Two-dimensional PAGE analysis of LMP antigens from unfractionated WEHI-3 extract (*a*), anti-H-2^d immunoprecipitate of WEHI-3 extract (*b*), peak LMP fraction (fraction 14, not immunoprecipitated) from Sepharose CL-6B column of WEHI-3 (*c*) and fraction 14 from the same column, but using IC21 extract instead of WEHI-3 (*d*). LMP chains are numbered in the schematic diagram (*e*) of the *H-2^d* haplotype pattern. Ia antigen α, β and invariant (I_i) chains are present in the immunoprecipitate (*b*) but not in the column fractions. The circle in *d* denotes the position of LMP chain 2, which seems to be absent from the *b* haplotype; the heavy arrow indicates its putative allelic form. Peptides denoted by the light arrows in *d* are probably not LMP chains, as they are also present in *H-2^k* haplotype column fractions (see Fig. 3*a*), but are not co-precipitated with the LMP complex from those cells (not shown).

the existence of a single LMP complex with a fixed stoichiometric ratio of subunits, rather than several types of complexes containing different ratios of the individual subunits and differing slightly in molecular size. However, it is formally possible that, in addition to the protein subunits already identified, non-^{35}S-methionine-labelled material (carbohydrates or peptidoglycans) are present in the LMP complex. In this respect, it may be significant that western blotting experiments have failed to reveal any such components (unpublished observations), indicating that if they do exist, they are probably not antigenic. When considered with the protein polymorphism data presented below, which indicate that only one of the LMP chains is polymorphic (and thus potentially antigenic) in the strain combinations used, these results argue strongly for a single complex containing all the LMP chains.

The antiserum we originally used to identify the LMP antigens was BALB.B (H-2^b) anti-BALB/c (H-2^d), which detects LMP antigens in the *a, d, f, ja, k, s, u, v* and *z* haplotypes. However, antisera made in the *d, k* or *s* haplotypes against the *H-2^b* haplotype fail to precipitate LMP-like polypeptides from *H-2^b* haplotype spleen cells or cell lines (J.J.M. & H.O.M., unpublished observations). In considering the possible function of the LMP antigens, it is important to decide between two possible explanations for this observation: (1) no LMP antigens are made in *b* haplotype mice or (2) although *b* haplotype mice synthesize LMP polypeptides, these are not immunogenic in *d, k* or *s* haplotype mice.

We can choose between these alternatives by using a non-immunochemical method of visualizing LMP antigens. Figure 2*d* shows the ^{35}S-labelled extract from the (H-2^b) IC21 cell line[9] manipulated in a manner identical to the WEHI-3 extract shown in Fig. 2*c*. At least 13 of the 16 LMP chains found in (H-2^d) WEHI-3 cells are also found in the IC21 cell line. LMP chains 4 and 16 are probably too weak to be seen in the IC21 gel (note that LMP chain 16 is also too weak to be seen in the immunoprecipitate shown in Fig. 2*b*). Thus, only one of the LMP chains found in WEHI-3 is clearly missing from the IC21 gel (LMP 2), and IC21 contains an extra chain which is not present in WEHI-3 (heavy arrow in Fig. 2*d*). Although definitive identification of the extra chain in the IC21 gel as part of the LMP complex will require either immunoprecipitation of the complex or peptide mapping/sequencing, this experiment strongly suggests that mice of the *H-2^b* haplotype produce a LMP complex similar to that in mice of other *H-2* haplotypes.

The above results are also consistent with the conclusion that the LMP are associated into a large complex; an apparent

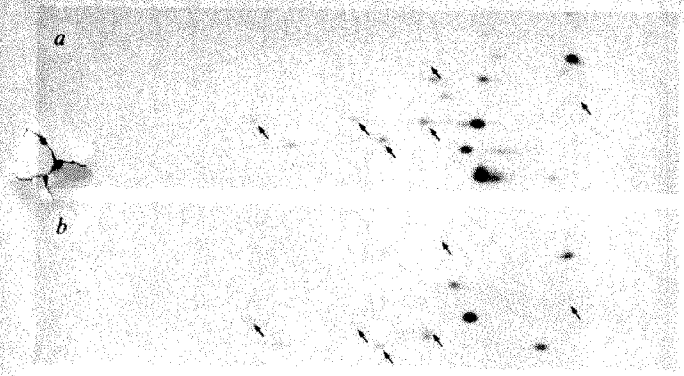

Fig. 3 Two-dimensional PAGE comparison of peak LMP column fractions (not immunoprecipitated) from the murine $H-2^k$ cell line UNC2 (*a*) and the human cell line, U937 (*b*). Chains which migrate to identical positions are denoted by arrows.

difference in only one of the peptides between the $H-2^b$ and $H-2^d$ haplotypes is sufficient to allow the production of an antibody which precipitates all 16.

As the gene products of the MHC have been highly conserved throughout evolution[5], one might expect that complexes similar to that described here would also be present in other species. The biochemical purification procedure described above might therefore allow the identification of such complexes in the absence of a specific precipitating antibody. Figure 3 shows a two-dimensional PAGE comparison of the peak LMP fraction from a murine cell line (UNC2, $H-2^k$)[10] and the corresponding fraction from the extract of a human cell line (U937)[11]. Although the patterns are not identical, the total number of chains present in this portion of the gel is similar, and at least six of the peptides from the human cell line migrate to exactly the same position as the corresponding murine LMP (arrows). It therefore seems likely that human cells do indeed contain a complex similar to the murine LMP complex. Definitive identification of these peptides as homologues of the murine LMP, and their genetic mapping, will, however, require further investigation.

Thus, both murine and human cells contain a large molecular complex composed of approximately 16 different polypeptide chains, all of which have a molecular weight of between 15,000 and 30,000. The unusual nature of this complex is highlighted by the fact that (non-immunoprecipitated) size-fractionated extracts can be made which, when electrophoresed in denaturing SDS gels, are seen to contain only LMP chains in the low-molecular weight portion of the gel. Thus, few or no other molecular species of similar size (M_r 500,000–650,000) contain any peptides of 15,000–30,000 M_r, whereas the LMP complex is composed entirely of subunits in this size range. (Although we have presented evidence elsewhere[6] that the multiple LMP chains are not simply proteolytic breakdown products of one or more larger molecule(s), we are currently attempting to verify this by characterizing the size of the messenger RNAs encoding the individual LMP chains.) In addition, excluding the ribosome (which has a molecular weight of $4–5 \times 10^6$ and may contain up to 80 different proteins[12]), we are unaware of any other biological macromolecule composed of so many different polypeptide chains. Thus, the LMP complex represents a unique macromolecular structure. That this unique structure is apparently conserved among species suggests that it is required for the proper functioning of the LMP complex. Experiments aimed at gaining insight into the nature of this function are underway.

We thank Drs V. Defendi, T. Gonwa and L. Lanier for providing us with the IC21, U937 and UNC2 cell lines, respectively. This work was supported in part by NIH grant AI-07757.

Role of γ-interferon in antibody-producing responses

H. James Leibson, Malcolm Gefter, Albert Zlotnik, Philippa Marrack & John W. Kappler

Interferon preparations, especially those containing γ-interferon (IFN-γ), have long been known to modulate immune responses[1–3]. However, because many studies used only partially purified interferons, it has been difficult to separate the immunoregulatory effects of the interferons from those of other biologically active molecules contaminating the preparations. Recently, with the cloning of the interferon genes in mouse and man, it has become possible to use these cloned interferons directly to test their effects in assays other than those involving the protection of cells from viruses. For example, cloned IFN-γ has been shown to be a potent inducer of Ia antigen expression on macrophages[4,5]. Similarly, cloned IFN-γ has been reported to act as a macrophage activation factors, as judged by the ability of activated macrophages to kill tumour cells *in vitro*[6]. We demonstrate here that cloned murine IFN-γ can also substitute for a late-acting helper factor which acts synergistically with other helper factors in the stimulation of B-cell antibody responses *in vitro*.

We have previously described[7] a murine T-cell hybridoma, FS7-20, which on stimulation with concanavalin A (Con A) produced at least five lymphokine activities: IFN-γ, macrophage activation factor (MAF), Ia-inducing factor (IaIF), a B-cell helper factor which we termed interleukin-X (IL-X), and interleukin-2 (IL-2). In studying a large panel of clones and subclones of FS7-20, we observed a random segregation of the ability to produce IL-2 from the ability to produce the other four lymphokine activities. On the other hand, IFN-γ MAF, IaIF and IL-X production were all tightly linked among these clones and subclones. We suggested that these four activities were probably due to the same molecular species, but we could not definitely rule out other possible explanations for the linkage or that some other common genetic control of production existed which varied among the clones and subclones of FS7-20. It had been suggested, and was later confirmed using cloned IFN-γ, that IFN-γ might act as IaIF and MAF[4–6,8], but an identity between IFN and IL-X was unexpected. Therefore, with the availability of cloned IFN-γ, we were particularly interested in testing its activity as a B-cell helper factor.

Our previous studies[9,10] had demonstrated that the optimal *in vitro* antibody responses of highly purified murine B cells to antigens such as sheep red blood cells (SRBC) required at least three different helper factors. The first was contained in preparations from normal macrophages or from the macrophage tumour cell line P388D1. The activity in these preparations has been indistinguishable from interleukin-1 (IL-1). The second factor preparation was the concentrated Con A-stimulated supernatant of the murine T-cell hybridoma, FS6-14.13 (ref. 11). Thus far the only known essential activity in this preparation has been IL-2 (refs 9, 10), although it remains possible that other as yet unidentified molecules in this supernatant contribute to

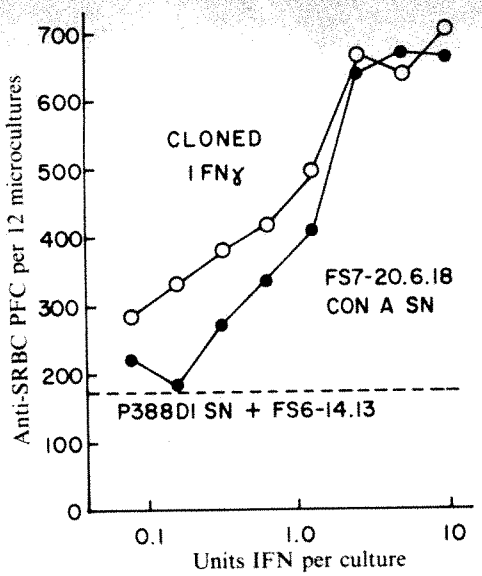

Fig. 1 IFN-γ is a B-cell helper factor. Data shown here are the sum of the anti-SRBC PFC obtained in 12 identical microculture wells of B cells incubated with P388D1 and FS6-14.13 supernatant (SN) clones (– – –) or with these supernatants and different numbers of units of IFN-γ contained in supernatants of the T-cell hybridoma FS6-20.6.18 (●) or derived from the cloned gene (○). **Methods:** Splenic B cells from (C57BL/6 × DBA/2)F_1 mice were purified by treatment *in vivo* with rabbit anti-mouse thymocyte serum (Microbiological Associates), and *in vitro* passage over Sephadex G-10 (Pharmacia) to remove macrophages, followed by treatment with a cocktail of anti-T-cell reagents and rabbit complement[9–11]. These B cells were incubated in 0.1-ml microcultures in limiting numbers (10^5 per well) with 0.005% SRBC and saturating concentrations of P388D1 supernatant (20%) as a source of IL-1 and 1 μl of a 50× concentrated supernatant from FS6-14.13 (containing 50 U μl IL-2) as a source of IL-2 and B-cell growth factor. 20 μl of supernatants containing different concentrations of IFN-γ were added at the optimal time, that is, after 24 h of culture. Supernatants were either dilutions of those induced by Con A treatment of the T-cell hybridoma FS7-20.6.18 (ref. 7), or dilutions of IFN-γ derived from the cloned gene[12,13]. The cloned gene was provided as a product purified from *E. coli* containing an expression vector that contained murine IFN-γ cDNA (specific antiviral activity of 8×10^6 U per mg protein)[12,13]. After 4 days' culture, wells were assayed for direct PFC against SRBC by standard techniques[9–11].

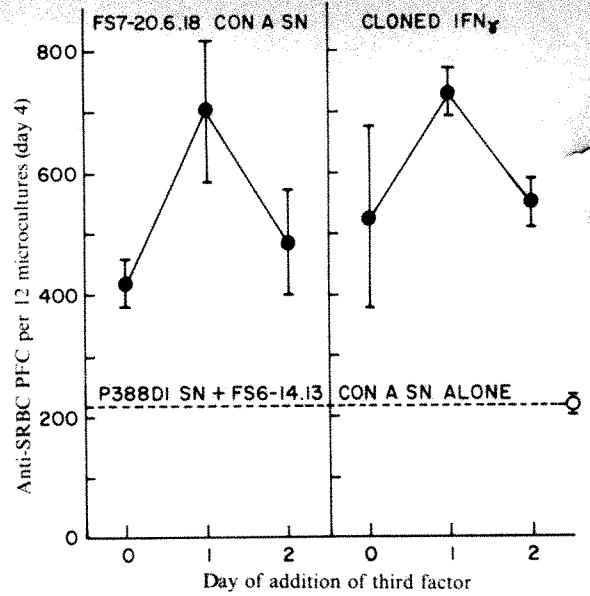

Fig. 2 IFN-γ is a late-acting helper factor. Cultures of purified B cells were set up as described in Fig. 1 legend with optimal concentrations of P388D1 and FS6-14.13 supernatants. Ten units of IFN-γ from either FS7-20.6.18 supernatant or from the cloned gene were added to the cultures on different days. After 4 days' total incubation the cultures were assayed for direct PFC against SRBC. Results shown are the total anti-SRBC PFC found in 12 identical microcultures.

its activity. The third required helper factor, which we termed IL-X because it did not correspond to any well-defined known molecule, was originally found in the 30,000–50,000 molecular weight fraction of an IL-2-depleted, Con A-stimulated supernatant of normal spleen cells. Its activity was assayed by its ability to enhance the antibody response of B cells to SRBC in cultures containing saturating amounts of IL-1 and IL-2 preparations. It was this activity which we later found in the Con A-stimulated supernatant of FS7-20 and whose production correlated strongly with that of IFN-γ.

To test directly whether IFN-γ could act as IL-X, we compared cloned IFN-γ produced in *Escherichia coli*[12,13] with a standard preparation of Con A-stimulated supernatant from FS7-20.6.18, a subclone of FS7-20 which produced high levels of IFN-γ and IL-X, but barely detectable levels of IL-2. Murine B cells were cultured for 4 days with SRBC, saturating amounts of IL-1 and IL-2 preparations and various concentrations of either cloned IFN-γ or the FS7-20.6.18 supernatant. Cultures were then assayed for anti-SRBC plaque-forming cells (PFC). The results are shown in Fig. 1. As we have reported previously[10], the combination of IL-1 and IL-2 stimulated a small anti-SRBC response from the B cells which was increased by addition of the FS7-20.6.18 supernatant (Fig. 1). The cloned IFN-γ produced a similar increase in the response (Fig. 1). For both preparations, the number of units of IFN-γ added predicted their relative activity in the PFC assay. Fifty per cent of the maximum stimulation was achieved with approximately one unit of IFN-γ per culture.

One of the properties distinguishing IL-X from IL-1 and IL-2 is that it can be added considerably later in the B-cell response. Whereas, to be fully effective, IL-1 and IL-2 must be added at the initiation of the response, the addition of IL-X can be delayed 1 or 2 days in a 4-day response[10]. To assess whether cloned IFN-γ behaved similarly, we again tested FS7-20.6.18 supernatant and cloned IFN-γ side by side in a kinetic experiment. B-cell cultures received SRBC, IL-1 and IL-2 on day 0 of a 4-day culture. On day 0, 1 or 2 the cultures received FS7-20.6.18 supernatant containing 10 U of IFN-γ or 10 U of cloned IFN-γ. Plaque responses were assayed on day 4. Stimulation of the response was seen again with both interferon preparations and as predicted, both preparations were active even when their addition was delayed 1–2 days, with day 1 being the optimal time of addition (Fig. 2). These results agree with our previous results using this activity isolated from normal T cells and distinguish the IFN-γ activity from that of IL-1 and IL-2.

Interferons have generally been reported as inhibitors of immune responses due to their anti-proliferative effects. However, there are several reports that interferon can be stimulatory, especially when added well into the proliferative phase of the response. In these studies, as in our own previous reports, unpurified interferon was used. The possibility that an associated non-interferon activity was responsible for the immunostimulation has always been a problem, especially when dealing with IFN-γ, which is produced from T cells and is therefore always contaminated with other lymphokine activities. In the present study, the use of IFN-γ produced from a recombinant DNA clone suggested that IFN-γ itself is stimulatory for B-cell antibody production.

In measuring B-cell helper factors *in vitro*, one must always consider the possibility that a particular factor may work indirectly by stimulating non-B cells contaminating the culture to produce additional activities. We have attempted to minimize this difficulty by developing and thoroughly testing B-cell purification techniques[9–11], and therefore believe it is highly likely that the IFN-γ activity in our experiments is due to its direct effect on the SRBC-responding B cell. This conclusion is

strengthened by the fact that despite an extensive search among normal T cells, hybridoma T cells and macrophage products, we have not identified an activity which can substitute for IFN-γ in this anti-SRBC B-cell response.

It is possible that some contaminant in the IFN-γ preparation from *E. coli*, for example lipopolysaccharide (LPS), is responsible for the effects on B-cell responses described here. The IFN-γ preparation we used is not mitogenic for B cells at concentrations containing 100 U ml^{-1} IFN-γ. Because effects on our cultures were seen at about 10 U ml^{-1} IFN-γ and because we have not seen similar effects with LPS at levels below 1 μg ml^{-1}, we consider this possibility unlikely. Moreover, the activity of our two IFN-γ-containing preparations (FS7-20.6.18 and cloned IFN-γ) is comparable in terms of units of IFN-γ. It is therefore highly unlikely that our results can be accounted for in any way other than that IFN-γ is responsible for the effects we measured.

Many laboratories have described T-cell-derived helper factors which stimulate B-cell antibody production. Such factors, which act late in the B-cell responses and do not seem to stimulate proliferation, have often been called T-cell replacing factor (or TRF) (reviewed in refs 15, 16). These activities have usually been defined in *in vitro* responses of murine B cells and are generally thought of as factors which stimulate the secretion of antibody from proliferating B cells. The question arises as to whether IFN-γ accounts for all T-cell-derived activities of this sort or whether other lymphokines can also provide this signal to B cells. As activities of this type have been reported in supernatants containing no detectable IFN-γ this is a distinct possibility. On the other hand, we have found that most of the late-acting TRF-like activity in the supernatants of mouse spleen cells stimulated with Con A, which presumably contain many if not all T-cell-derived lymphokines, has the properties of murine IFN-γ, that is, it has an apparent molecular weight of 40,000 on Sephadex gel filtration and is inactivated by incubation at *p*H 2. These findings suggest that IFN-γ is in fact a major component of TRF activities from normal lymphocytes. The lymphokine(s) responsible for driving the later events of B-cell maturation *in vivo* remains to be identified and will be the subject of future investigations.

Finally, one of the well known effects of IFN-γ which may be significant here is its inhibitory effects on cell proliferation. As IFN-γ is late acting, and in its capacity as a TRF is thought to stimulate differentiation of B cells to antibody secretion, this may be yet another example of a substance which inhibits cell division and simultaneously stimulates differentiation[14].

We thank Genentech, Inc. for the gift of γ-interferon produced in *E. coli*. This work was supported by USPHS grants AI-17134 and HL-27353 and by American Cancer Society, Inc. research grant IM-319.

γ-Interferon is one of several direct B cell-maturing lymphokines

Two classes of molecules often released after the interaction of T lymphocytes, macrophages and antigen are B-cell maturation factors (BMF)[1–3] and immune (γ) interferon (IFN-γ)[4–7]. BMFs directly induce the maturation of resting B lymphocytes to the state of active immunoglobulin secretion[1–3], while IFN-γ is defined by the reduction of viral infectivity *in vitro*[8,9]. However, interferons have been shown to have a variety of effects[10–17] and they have also been reported both to increase and decrease B-cell differentiation in intact animals and complex cellular mixtures *in vitro*[18–25]. Here we show that murine IFN-γ produced by recombinant DNA technology[26] shows similar biological effects to BMFs from two other sources. All three preparations induce immunoglobulin secretion by both normal resting murine splenic B cells and the comparable B-cell tumour line WEHI-279.1 (refs 1, 3). IFN-γ and the other two BMFs are not identical, however, as anti-IFN-γ antibodies block the effects on B cells of IFN-γ, but not those of the other two lymphokines. IFN-γ may be one of several molecules with a direct role in driving the maturation of resting B cells to active immunoglobulin secretion.

We and others have recently begun to use inducible monoclonal cell lines, including tumours, as assay systems for lymphokines[1–3,27–29] as they overcome problems of interacting cell populations inherent in the use of more complex assay systems. Culture supernatants from the antigen-stimulated monoclonal helper T-cell line S26.5 (kindly provided by Dr M. Schreier)[1,30,31] are able to induce terminal differentiation to active IgM secretion in the B-cell tumour line WEHI-279.1 and also in comparable normal resting murine splenic B cells[1,3]. A second source of such maturational lymphokines is supernatant from cultures of spleen cells from mice homozygous for an autosomal recessive mutation known as viable motheaten (*me^v*). Viable motheaten homozygotes (*me^v*/*me^v*) show polyclonal immunoglobulin production (mostly of the IgM class) and autoimmune disease[32]. B-cell maturation in response to these lymphokines does not require interactions with other cells, occurs in most of the B cells present (under optimum culture conditions), is quite rapid (peak immunoglobulin secretion at days 2–3 of stimulation) and involves all of the pre- and post-translational alterations in IgM metabolism known to occur in the transition of normal resting B cells to immunoglobulin-secreting plasma cells[1,3]. The resulting immunoglobulin secretion has been measured by biosynthetic radiolabelling followed by immunoprecipitation, by enzyme-linked immunosorbent assays or, as done here, by a reverse plaque assay[33] which reveals the number of immunoglobulin-secreting cells in culture at the time of assay. To test directly the effects of IFN-γ in these B-cell maturation assays, we have used IFN-γ produced by CHO cells transfected[34] with a plasmid containing the cloned mouse IFN-γ gene[26]. This IFN-γ should be glycosylated and secreted similarly to that from normal T cells.

Culture supernatants from S26.5 T cells, *me^v* spleen cells and IFN-γ were titrated individually into cultures of either resting spleen cells from normal mice or WEHI-279.1 tumour B cells. The numbers of (immunoglobulin-secreting) plaque-forming cells (PFC) were determined 3 days later by the polyclonal reverse plaque assay[33]. As seen in Fig. 1, both normal (*a*) and tumour (*b*) B cells responded similarly to all three supernatants with an approximately 10-fold increase in PFC per culture. Cloned IFN-γ is clearly an effective BMF as measured in this

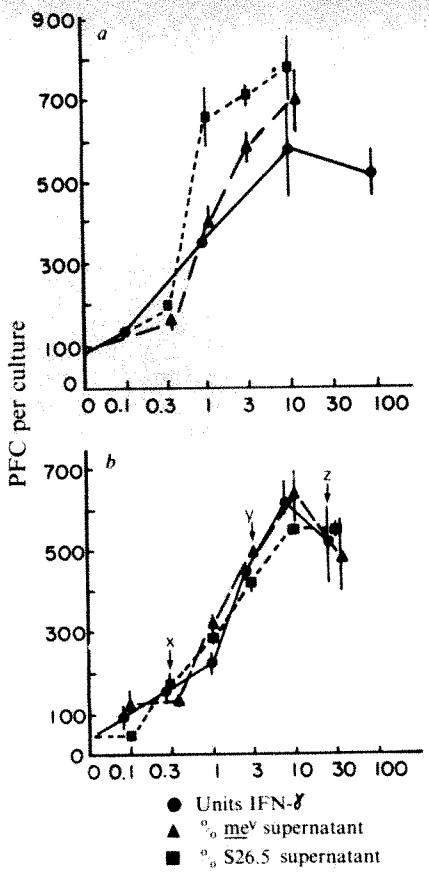

Fig. 1 Dose–response titrations of lymphokines from three sources. Antigen-stimulated S26.5 helper T-cell supernatant (■) (prepared as described[1]), non-stimulated *me*^{v} spleen cell supernatant (▲) (prepared by culturing *me*^{v} spleen cells at 10^7 per ml for 2 days) and supernatant from CHO cells transfected with plasmid containing the cloned murine IFN-γ gene (●) were tested on *a*, Percoll gradient-purified (that is, resting) C57BL/6J, DBA/2J or BALB/cBy spleen cells[1], or *b*, WEHI-279.1 (ref. 37) tumour B cells. Spleen cells were cultured in Iscove's modified Dulbecco's medium supplemented with albumin, transferrin and soybean lipids (IMDM-ATL)[38], while WEHI-279.1 cells were cultured in RPMI 1640-based medium containing 10% fetal bovine serum plus other supplements[3]. Cells were cultured at 10^3 per 0.2 ml flat-bottomed microwell at 37 °C in 5% CO_2/air, and the number of immunoglobulin-secreting cells (PFC) were determined on day 3 by the Protein A reverse plaque assay[33]. Percentages of the various supernatants, or amounts of IFN-γ activity were added to the cultures as shown. (The IFN-γ concentration in the undiluted CHO supernatant was 16,000 U ml^{-1}, as tested in an inhibition of cytopathic effect assay using encephalomyocarditis virus as the challenge virus and murine L929 cells as targets[9]. Data shown represent the mean ± s.e.m from two to four determinations each. Points x, y and z are referred to in Fig. 2 legend.

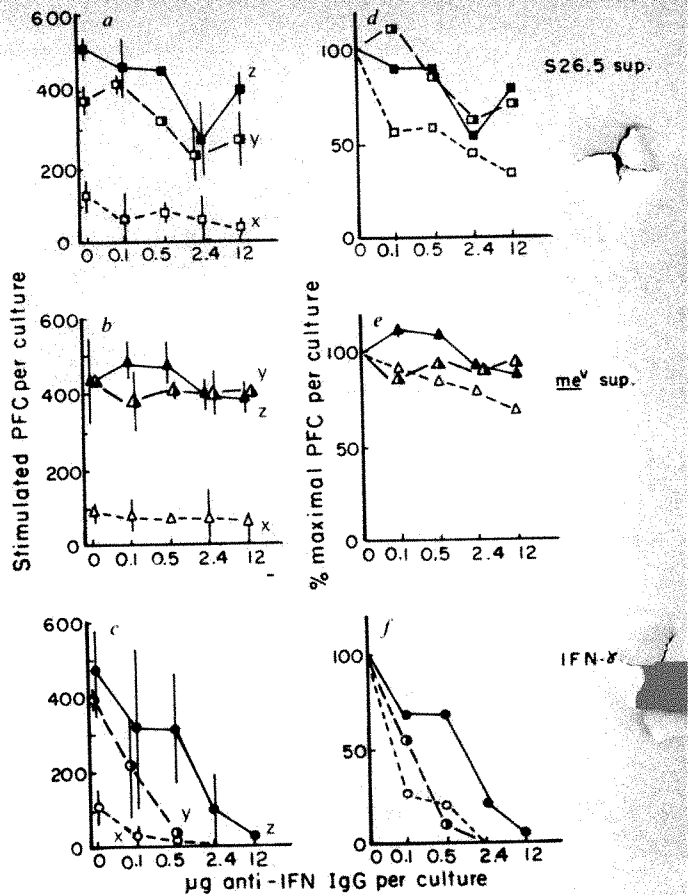

Fig. 2 Inhibition of lymphokine activities by rabbit anti-mouse IFN-γ antibodies. The indicated amounts of anti-IFN-γ IgG (capable of neutralizing 16 units of IFN-γ per μg) were added to the stimulatory lymphokine dose 30 min before WEHI-279.1 cells were added to the cultures. Culture conditions and harvesting were as described in the legend to Fig. 1. Panels *a*, *b* and *c* show stimulated PFC (that is, PFC over background), while panels *d*, *e* and *f* represent the same data expressed as the percentage of the response to that lymphokine concentration but without anti-IFN-γ IgG. *a*, *d*, Responses to S26.5 supernatant. *b*, *e*, Responses to *me*^{v} supernatant. *c*, *f*, Responses to IFN-γ supernatant. The curves indicated by open symbols and dotted lines refer to the minimum lymphokine concentrations indicated by x in Fig. 1*b*; the curves indicated by half-closed symbols and dashed lines refer to the near-maximal lymphokine concentrations indicated as y in Fig. 1*b*; and the curves indicated by closed symbols and solid lines refer to the super-optimal lymphokine concentrations indicated as z in Fig. 1*b*.

direct assay system. Control supernatants derived from CHO cells not transfected with IFN-γ-containing plasmids showed no PFC induction (data not shown).

When tested directly for inhibition of viral infectivity, S26.5 supernatant showed substantial IFN activity (500 U ml^{-1}), while *me*^{v} supernatant did not show detectable IFN levels (<10 U ml^{-1}). Therefore, we next tested whether anti-IFN-γ antibody (made in rabbits against partially-purified mitogen-induced mouse IFN-γ)[35] could inhibit the B-cell responses stimulated by the three different lymphokine preparations (Fig. 2). This antibody has been shown previously to block efficiently the anti-viral action of purified, naturally produced IFN-γ, but not to affect CSF, IL-1 and IL-2 (ref. 36). Varying amounts of IgG from the anti-IFN-γ antiserum were added to cultures containing WEHI-279.1 cells plus either barely stimulatory, almost maximally stimulatory, or supersaturating amounts of the three lymphokine preparations (doses labelled x, y and z respectively, on Fig. 1*b*). Fig. 2*a–c* shows the actual PFC responses seen in these cultures, while Fig. 2*d–f* shows the responses as percentages of the maximal response seen with that concentration of lymphokine but without anti-IFN-γ antibody. All doses of IFN-γ were completely inhibited by anti-IFN-γ antibody (Fig. 2*c* and *f*), with proportional amounts of anti-IFN-γ being required to inhibit different doses of IFN-γ. At the opposite extreme, no amount of anti-IFN-γ antibody tested produced a significant inhibition of the PFC response to any dose of lymphokine from *me*^{v} mice (Fig. 2*b* and *e*). The responses to supernatant from S26.5 T helper cells were partially inhibited, but no amount of anti-IFN-γ antibody used in these experiments was able to block completely the PFC response to even the lowest amount of S26.5 supernatant (Fig. 2*a* and *d*). Normal rabbit IgG was tested as a control for the anti-IFN-γ IgG and showed no inhibitory or stimulatory effects (data not shown). Rabbit (and murine) monoclonal antibodies to recombinant DNA-produced IFN-γ have also recently been tested, and shown to act like the rabbit antibodies to naturally-produced IFN-γ used here (data not shown).

To quantitate how much of the B-cell maturational activity in each lymphokine preparation might be due to IFN-γ, dose–response titrations were performed in the presence and absence

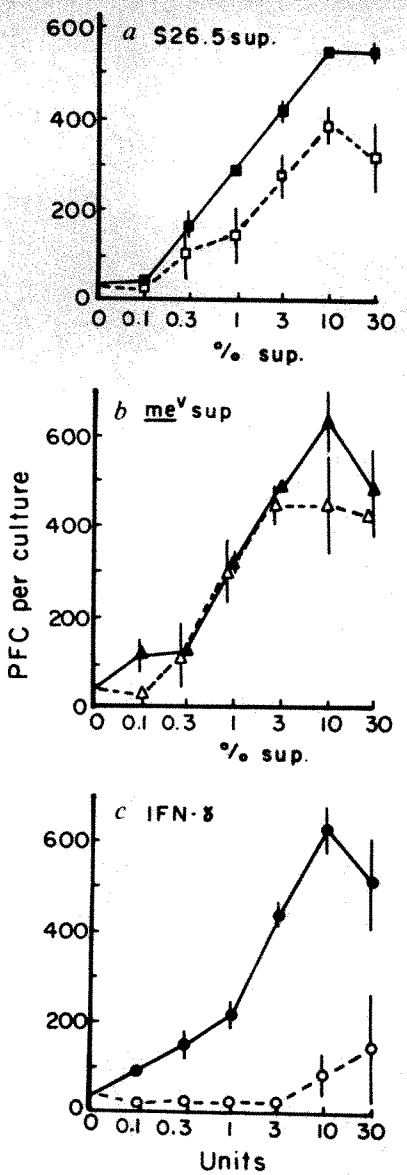

Fig. 3 Comparison of lymphokine titrations in the presence and absence of anti-IFN-γ antibody. The three lymphokine preparations were titrated into cultures of WEHI-279.1 cells as indicated in the legend to Fig. 1*b*. The solid symbols and lines indicate cultures with no anti-IFN-γ antibody, while the open symbols and dotted lines indicate cultures where 2.4 μg of anti-IFN-γ IgG (see Fig. 2—enough to block even the highest IFN-γ dose used here) were added to the lymphokines 30 min before the cells. *a*, S26.5 supernatant; *b*, *me*^{v} supernatant; and *c*, IFN-γ.

of sufficient anti-IFN-γ antibody to block a 10-fold superoptimal dose of IFN-γ (Fig. 3). As shown in Fig. 3*c*, the presence of this amount of anti-IFN-γ antibody shifted the dose–response curve for IFN-γ by about 100-fold, indicating that close to 100% of the activity in this supernatant is due to IFN-γ. The dose–response curve of the *me*^{v} supernatant (Fig. 3*b*) was not affected by the anti-IFN-γ antibody, suggesting that little (less than a few per cent) of the activity of this supernatant is due to IFN-γ. About half of the direct B-cell maturational activity in S26.5 supernatant appears to be due to IFN-γ, as this dose–response curve was shifted 2- to 3-fold by anti-IFN-γ (Fig. 3*a*).

From these experiments it can be concluded that IFN-γ functions as a direct B cell-maturing lymphokine, driving non-immunoglobulin-secreting normal and tumour B cells to active immunoglobulin secretion. In a representative experiment, 200 fluorescent-activated cell sorter (FACS)-purified normal resting BALB/cBy splenic B cells yielded 3 ± 1 PFC per culture on day 3 without added lymphokine, and 130 ± 14, 150 ± 14 and 130 ± 14 PFC with S26.5, *me*^{v} and IFN-γ supernatants, respectively. The comparable behaviour of monoclonal tumour B cells, normal resting splenocytes and FACS-purified resting B cells suggests that the induction of active immunoglobulin secretion occurs via the direct interaction of IFN-γ and the target B cells, without the required involvement of other cell types or signals. The effects of IFN-γ produced by recombinant DNA technology indicate that the active molecule is indeed IFN-γ, rather than another lymphokine which may also be found in naturally produced IFN-γ preparations. Previous studies have suggested both stimulatory and inhibitory effects of interferons on B-cell function, but always in the context of modulating the effect of another primary inductive signal (either antigen or mitogen) in complex cellular mixtures[10,18].

A second conclusion is that at least one, and probably two, other direct B cell-maturing lymphokines exist which are distinct from IFN-γ. These lymphokines may be related to IFN-γ, but do not show the anti-viral effects, nor the major antigenic determinant(s) seen by anti-IFN-γ antibodies, nor identical biochemical properties to IFN-γ. The non-IFN-γ BMF from S26.5 supernatant is less hydrophobic than IFN-γ—fractions 80–104 of the phenyl-Sepharose hydrophobic column shown in Fig. 3 of ref. 2 do not show anti-viral activity, and their BMF activity is not affected by anti-IFN-γ antibodies, whereas fractions 105–130 do show anti-viral activity and their BMF activity is completely blocked by anti-IFN-γ antibodies (data not shown). The *me*^{v} lymphokine is both smaller on gel filtration (molecular weight 15,000 compared with 50,000) and more acidic (*p*I 4 compared with 5.5) than IFN-γ (unpublished results). IFN-γ and the non-IFN-γ BMF molecules from S26.5 and *me*^{v} supernatants thus seem to be distinct and separable species.

Since IFN-γ is active in inducing the terminal maturation process which is central to the humoral immune response, and also influences the expression of specific macromolecules and cellular activities in other cell types[10–25], it is not clear whether the anti-viral activity for which IFN-γ was named represents its primary physiological function. In any case, the actual *in vivo* role of IFN-γ in humoral immune response induction, and its structural and functional relationships to the other molecule(s) with similar activity, will be important questions for future investigations.

Platelet-derived growth factor[1–4] (PDGF) is known to be involved in regulating the mitosis of connective tissue cells, and recent studies have also shown that it may function in mediating cellular transformation[5–8]. The oncogene carried by simian sarcoma virus, *sis*, is homologous to one chain of PDGF[5–8], and treatment of non-neoplastic cells with this growth factor results in increased transcription of another oncogene, *myc* (ref. 9). PDGF also stimulates the synthesis of proteins that are characteristic of transformed cells[10]. However, phenotypic transformation does not appear to result from the action of PDGF alone. For example, expression of *myc* does not transform cells in the absence of other oncogene expression[11]. We have recently shown that platelets contain another peptide growth factor, transforming growth factor-β (TGF-β)[12,13], in addition to PDGF. We report here that extracts of human platelets can induce anchorage-independent growth of non-neoplastic rat kidney (NRK) fibroblasts, but that purified PDGF alone does not elicit this effect. Rather, the transforming activity of the platelet extract is due to a concerted action of three distinct peptides: PDGF, TGF-β and a newly identified analogue of epidermal growth factor (EGF).

NRK fibroblasts are non-neoplastic, contact-inhibited cells that are indicators of phenotypic transformation. With the appropriate stimulus, these cells undergo anchorage-independent growth as assayed by colony formation in medium containing agar[14,15]. An acid–ethanol extract of human platelets induces phenotypic transformation of NRK fibroblasts (Fig. 1*a*). Homogeneous PDGF[16] does not induce anchorage-independent growth of the cells even when used at concentrations 10–20-fold greater than that required for half-maximal stimulation of DNA synthesis (Fig. 1*b*).

The results shown in Fig. 1 suggest that other components in the platelet extract, acting alone or in combination with PDGF, are responsible for the induction of phenotypic transformation. In fact, previous studies have shown that platelets contain a type-β transforming growth factor[12,13]. Figure 2*a* shows the elution position of this peptide during gel-filtration on a column of Bio-Gel P-60. TGF-β can induce anchorage-independent growth of NRK cells, but expression of this biological activity requires a synergistic interaction with EGF or a peptide resembling EGF (TGF-α)[12,17,18]. We can detect a new EGF-like peptide in human platelets by gel-filtration of the extract, adding purified TGF-β[12] to aliquots of the column fractions, and then assaying the samples for the ability to induce anchorage-independent growth (Fig. 2*b*). Column fractions 80–90 contain EGF-like activity as determined by synergism with TGF-β in the bioassay (Fig. 2*b*) and competition with ^{125}I-labelled EGF in a radioreceptor assay (Fig. 2*c*). Control studies showed that the biological activity of these fractions decreased at least 10-fold when assayed in the absence of TGF-β. The apparent molecular weight (M_r) of this platelet-derived, EGF-like peptide is 27,000

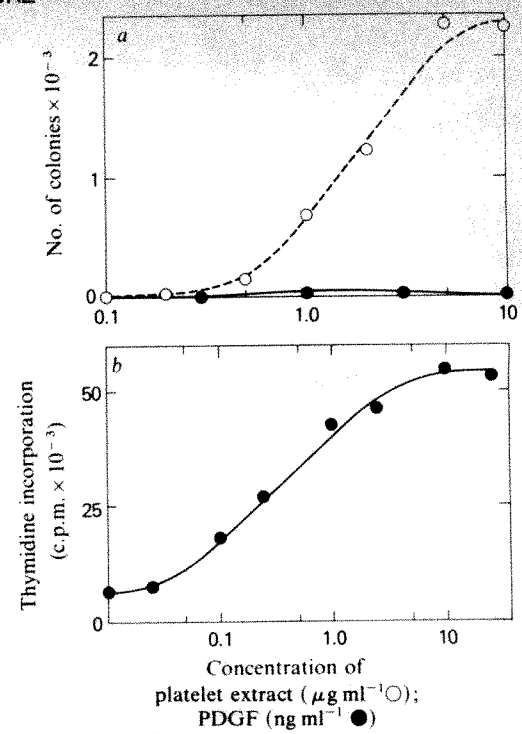

Fig. 1 Relative transforming activity of platelet extracts and PDGF. The acid–ethanol extract of human platelets was prepared and quantitated as described elsewhere[12]. *a*, The ability of the extract (○) or homogeneous PDGF[16] (●) to induce anchorage-independent growth of NRK fibroblasts as measured by the formation of colonies (>3,000 μm² per dish, ordinate) in soft agar. The concentrations of extract and PDGF (abscissa) are shown on logarithmic scale. This assay was performed in medium containing calf serum (10%, Gibco)[12,41]. *b*, The ability of purified PDGF to stimulate ^{3}H-thymidine incorporation into NRK fibroblasts (see ref. 12 for procedures).

as determined by gel-filtration (Fig. 2) and 24,000 as determined by preparative SDS-polyacrylamide gel electrophoresis[19]. (Fractions 84–88 were pooled, freeze-dried, and an aliquot of the residue was run on a 12.5% SDS gel. The gel was sliced, and eluted proteins[20] were assayed for the ability to induce anchorage-independent growth of NRK fibroblasts in the presence of TGF-β.) The EGF-like biological activity of this polypeptide shows that it is not the binding protein for EGF[21,22]. Its stability to both acidic *p*H (see Fig. 2 legend) and SDS-gel electrophoresis shows that it is distinct from the EGF-binding protein complex[21,22]. It was also possible that the 'new' peptide was PDGF, because PDGF, acting through its own receptor, can inhibit the binding of labelled EGF to the EGF receptor[23,24]. The EGF-like peptide identified in Fig. 2 is not PDGF; this new peptide competes with ^{125}I-labelled EGF in a radioreceptor assay using cells, line A431, that lack PDGF receptors[25–27] (Fig. 2*c*).

Oka and Orth[28] have recently suggested that human platelets contain both pro- and authentic EGF (M_r 33,000 and 6,000) as determined by reactivity in a human EGF immunoassay. The relationship between the larger peptide they detect and the EGF-like activity we detect using receptor binding competition (see Fig. 2) is not clear, but specific chemical modification studies indicate that the new growth factor described in Fig. 2 is intrinsically distinct from EGF (Fig. 3). Treatment of this platelet peptide with cyanogen bromide (CNBr) does not alter its affinity for the EGF receptor (Fig. 3*b*) despite the fact that: (1) amino acid analysis of the partially purified platelet peptide before and after CNBr treatment showed that cleavage at methionyl residues was complete, (2) EGF treated in parallel with CNBr showed the expected decrease[29,30] in receptor binding affinity (Fig. 3*a*), and (3) deliberate contamination of pure EGF with a large excess of protein (so that is was less pure than the preparation of the platelet-derived EGF-like peptide;

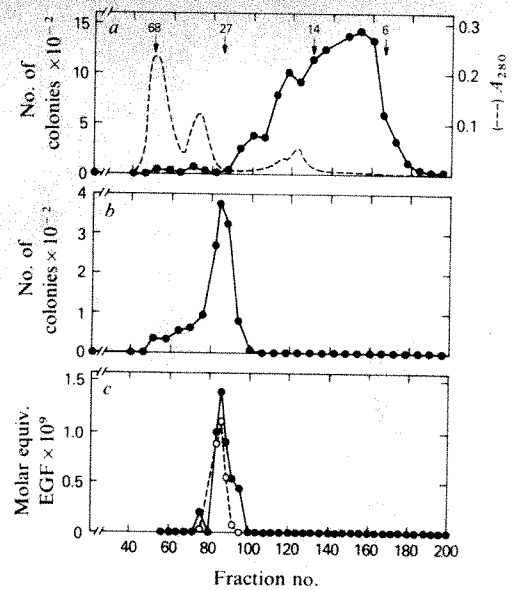

Fig. 2 Gel filtration of the human platelet extract on Bio-Gel P-60. *a*, Protein profile as determined by absorbance at 280 nm (– – –). Vertical arrows show, from left to right, the elution positions of bovine serum albumin ($M_r = 68{,}000$; V_0), chymotrypsinogen A ($M_r = 27{,}000$), lysozyme ($M_r = 14{,}000$) and insulin ($M_r = 6000$), respectively. ●, Elution position of platelet-derived TGF-β determined by colony formation (>9,000 μm^2) induced in the presence of pure murine EGF[42] (0.5 nM) and 2.5 μl of selected column fractions. *b*, Elution position of the platelet-derived, EGF-like peptide determined by colony formation (>9,000 μm^2) induced in the presence of homogeneous TGF-β (20 pM, prepared as described in ref. 12) and 250 μl of selected column fractions. *c*, Elution position of material that competes for the binding of ^{125}I-labelled EGF to the EGF receptor of NRK fibroblasts (●) and A431 cells (○).

Methods: The acid–ethanol extract of platelets (250 units) was solubilized in 1 M acetic acid (100 ml) and applied to a column (10 × 100 cm) of Bio-Gel P-60 which had been equilibrated in the sample solvent (1 M acetic acid, pH ~ 2). Fractions containing 35 ml were collected at a flow rate of 100 ml h^{-1}. The radioreceptor assay was performed similarly to the described procedure[34]. Cells were suspended (2×10^5 NRK cells ml^{-1} or 1×10^4 A431 cells ml^{-1}) in medium (Dulbecco's modified Eagle's medium with gentamycin) containing 10% fetal bovine serum (Bio-Fluids, Rockville, Maryland), seeded in 24-well plates (1 ml of the cell suspension per well), and incubated overnight (37 °C, humidified atmosphere of 10% CO_2 in air). Aliquots of selected column fractions (120 μl) were dried in the presence of bovine serum albumin (20 μg) in a vacuum desiccator. The residues were dissolved in 4 mM HCl (20 μl), diluted with binding buffer[34] (0.2 ml) containing ^{125}I-labelled EGF (about 2×10^5 c.p.m.), and incubated with washed cells as described previously[34]. Receptor binding competition data were converted to molar equivalents of EGF using pure murine EGF as the standard.

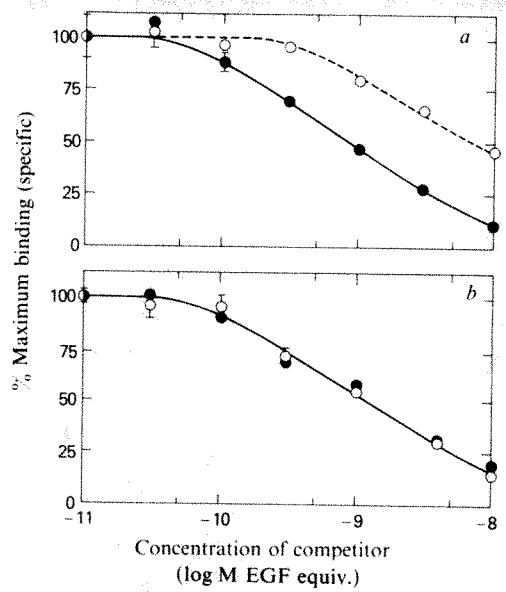

Fig. 3 The effect of CNBr on the receptor binding affinity of murine EGF (*a*) and the human platelet-derived EGF analogue (*b*). Results were obtained by measuring the ability of these peptides to compete with ^{125}I-labelled EGF for binding to the EGF receptor of NRK fibroblasts. The binding of labelled EGF to the cells was performed as described in Fig. 2 legend. Samples contained selected amounts of EGF or the platelet-derived EGF analogue, native (●) or after treatment with CNBr (○). Maximal binding of labelled EGF (determined in the absence of unlabelled competitor) was about 1,000 c.p.m.; nonspecific binding (determined in the presence of 10^{-7} M EGF) was about 150 c.p.m.

Methods: Treatment of EGF (0.5 nmol, 1 residue methionine per mol EGF[35,36,42,43]) and the partially purified EGF analogue (4×10^{-12} mol equivalents of EGF as determined by receptor binding competition; 0.5 nmol methionine in total protein as determined by amino acid analysis) with CNBr (0.25 μmol per sample) was performed in 70% formic acid (50 μl per sample) for 20 h at 23 °C. Native samples of EGF and the EGF analogue were treated in parallel in the absence of CNBr. After the reaction period, portions (10%) of the samples were removed for amino acid analysis. (Methionine values were decreased >90% by the CNBr treatment; other amino acids were not affected.) To ensure complete removal of CNBr and formic acid, the remainder of each sample was dried under a gentle stream of nitrogen (in the presence of bovine serum albumin, 100 μg), the residues were dissolved in 4 mM HCl (200 μl), and the resulting solutions were freeze-dried overnight. For the control studies, EGF (70 pmol) was deliberately contaminated with a large excess of protein (myoglobin, 60 nmol) before treatment with CNBr. The data are plotted as the mean of duplicate determinations using error bars to show the range (when observed).

see Fig. 3 legend) did not prevent its reaction with CNBr. Thus, the new EGF analogue in human platelets lacks a methionine residue critical to receptor binding.

Figure 4 shows the biological interactions between the three platelet-derived growth factors described above. In this experiment, cells were cultured in soft agar containing plasma-derived serum (rather than whole-blood derived serum) in order to decrease the basal levels of platelet peptides. Homogeneous PDGF in combination with either TGF-β alone or murine EGF alone does not efficiently induce phenotypic transformation (Fig. 4*a*). Similarly, TGF-β in conjunction with murine EGF can only minimally stimulate anchorage-independent growth in this system if the concentration of added PDGF is less than 0.1 ng ml^{-1} (Fig. 4*a*). When platelet-derived peptides are absent from the basal assay medium, phenotypic transformation requires the addition of all three growth factors (Fig. 4*a*). In three separate experiments, PDGF (3 ng ml^{-1}) 'restored' the activity of TGF-β (20 pM) and murine EGF (0.5 nM) to 50, 100 and 65% of that observed with autologous 10% whole-blood derived serum. Furthermore, Fig. 4*b* shows that in a plasma-derived system, the human platelet-derived EGF analogue efficiently synergizes with PDGF and TGF-β to induce transformation.

Recent studies have emphasized the relationships between PDGF and oncogenesis[5–10]. The results described here show that PDGF alone does not induce transformation in NRK cells, but that it acts in concert with platelet-derived TGF-β and EGF-like peptides. These data agree well with previous studies indicating that PDGF controls proliferation by modulating the response of cells to other growth factors[31–33]. Mechanistically, TGF-β can increase the number of cell-surface receptors for EGF and alter their down-regulation in response to ligand binding[34]. The platelet-derived EGF analogue can bind to these receptors (Figs 2, 3) and exert EGF-like effects (Fig. 4). This

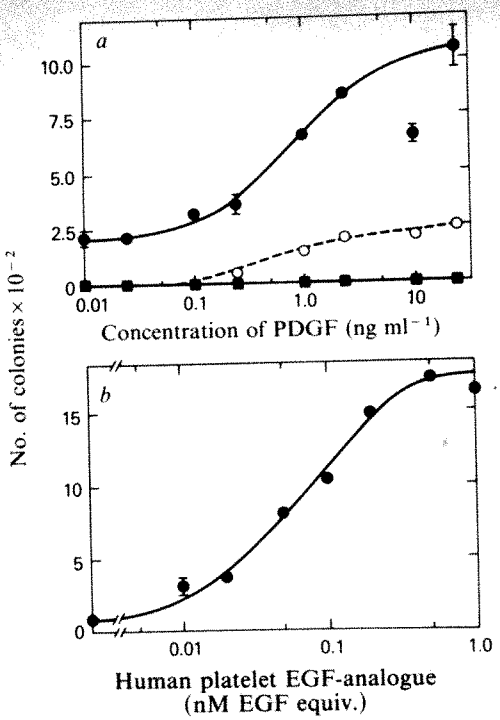

Fig. 4 Biological interaction of the three platelet-derived growth factors. The amount of PDGF in the samples was varied (abscissa, logarithmic scale). The concentrations of TGF-β and EGF were constant at 20 pM and 0.5 nM, respectively. *a*, Colony-forming activity of NRK fibroblasts (colonies >3,000 μm^2) in the presence of PDGF, TGF-β and EGF (●); PDGF and TGF-β (■); or PDGF and EGF (○). *b*, The ability of the human platelet-derived EGF analogue to induce colony formation of NRK cells in soft agar when assayed in medium containing 10% plasma-derived serum, TGF-β (20 pM) and PDGF (3 ng ml^{-1}).
Methods: The assay was performed as before[12,41] except that the medium contained 10% plasma-derived serum (bovine) rather than 10% calf (whole blood-derived) serum. TGF-β, PDGF and murine EGF were purified to homogeneity[12,16,42]. The platelet-derived EGF analogue was partially purified by gel filtration (see Fig. 2) and HPLC on a C_{18} column (Vydac, semipreparative) using 0.1% trifluoroacetic acid (TFA) as the stationary phase and 0.1% TFA in an acetonitrile gradient as the mobile phase (10–40% acetonitrile in 3 h, 0.8 ml min^{-1}). Fractions containing 0.8 ml were collected. The elution position of the EGF analogue (about 15% acetonitrile) and its quantitation were determined by assaying aliquots of column fractions in the radioreceptor assay with A431 cells (see Fig. 2 legend for details). Plasma-derived serum (10% in medium) was prepared by adding fresh bovine plasma (11 ml) to medium (100 ml of Dulbecco's modified Eagle's medium containing gentamycin). A fibrin clot formed and retracted during overnight incubation at 37 °C. After removal of the clot, the resulting solution was sterilized by filtration. Autologous bovine whole-blood derived serum (10% in medium) was prepared similarly using the serum from freshly clotted whole blood. The plasma and serum were derived from the same bleeding.

new growth factor is structurally distinct from authentic EGF as judged by its apparent larger molecular weight and by the absence of a methionine residue critical to receptor binding (the methionine at position 21 in both human[35] and murine[36] EGF). In the latter regard, this analogue resembles the type α transforming growth factors[15,17] which are EGF-like peptides lacking methionine[37,38]. Similarly, this critical methionine residue is absent from the potential EGF-related peptides encoded in the mouse EGF mRNA[39,40]. Our results show that the human platelet contains at least three distinct growth factors and that, in the presence of plasma, the interaction of these three peptides can induce transformation of fibroblastic cells.

We thank Drs Charles D. Stiles and Harry N. Antoniades for gifts of homogeneous PDGF standards, Dr Anita B. Roberts for critical review of the manuscript, and Mrs Margaret Konecni and Ms Susan Perdue for assistance in preparing the manuscript.

Human epidermal growth factor receptor cDNA is homologous to a variety of RNAs overproduced in A431 carcinoma cells

The recently discovered similarity between the human epidermal growth factor (EGF) receptor and the avian erythroblastosis virus v-*erb-B* protein[1] supports the hypothesis that viral oncogenes share a common evolutionary origin with genes encoding growth-regulating cell-surface receptors. To elucidate the relationship between receptors and malignant transformation, we have now used a fragment of v-*erb-B* as a probe to screen a cDNA library of mRNA from A431 human carcinoma cells, which possess a large number of EGF receptors[2]. Of the six clones isolated, the largest (pE7)

contains an insert of 2.4 kilobase pairs (kbp) whose deduced amino acid sequence is homologous to the v-*erb-B* protein and identical to reported EGF receptor peptide sequences[1]. This pE7 cDNA hybridized to three prominent RNAs of ~10, 5.6 and 2.9 kilobases (kb), and to three minor species of 6.3, 4.6 and 3.3 kb. All were present in elevated levels in A431 cells. The prominent 2.9-kb RNA was homologous only to the 5′ portion of the pE7 insert. This result raises the possibility that differential RNA processing is used by A431 cells to generate a variety of RNAs.

EGF elicits a wide variety of rapid and delayed responses mediated via specific high-affinity cell-surface receptors[3]. These responses to EGF are dependent on the occupation of functional receptors at the cell surface. Short-term effects of EGF include activation of transport systems[4–6] and increased protein phosphorylation[7]. Delayed responses include stimulation of DNA, RNA and protein synthesis that ultimately results in cell proliferation[8–10].

The EGF receptor is a glycoprotein of molecular weight 170,000 which has been identified in many types of cells[11–15]. The receptor has an EGF-stimulated protein kinase activity, which phosphorylates itself and other substrates on a tryosine residue[7]. Regulation of the cellular response to EGF can occur through ligand-induced 'down regulation' of the receptor[16–20].

Recently, six different peptides from the EGF receptor have been isolated, sequenced and found to be strikingly similar to the deduced amino acid sequence of v-*erb-B*[1]. The latter is the protein product of the *erb-B* gene of avian erythroblastosis virus (AEV) which induces both erythroblastosis and sarcomas in infected birds[21,22]. Most mammalian cells contain homologous counterparts to the viral transforming genes[23,24], whose enhanced expression is thought to produce the malignant phenotype[25–27]. The strong similarity in protein structure between v-*erb-B* and the EGF receptor supports the idea that the human cellular homologue to v-*erb-B* (c-*erb-B*) may be the same gene as that coding for the EGF receptor. This hypothesis is reinforced by the finding that the c-*erb-B* gene and the EGF receptor gene are both localized on the same region of human chromosome 7 (refs 28, 29).

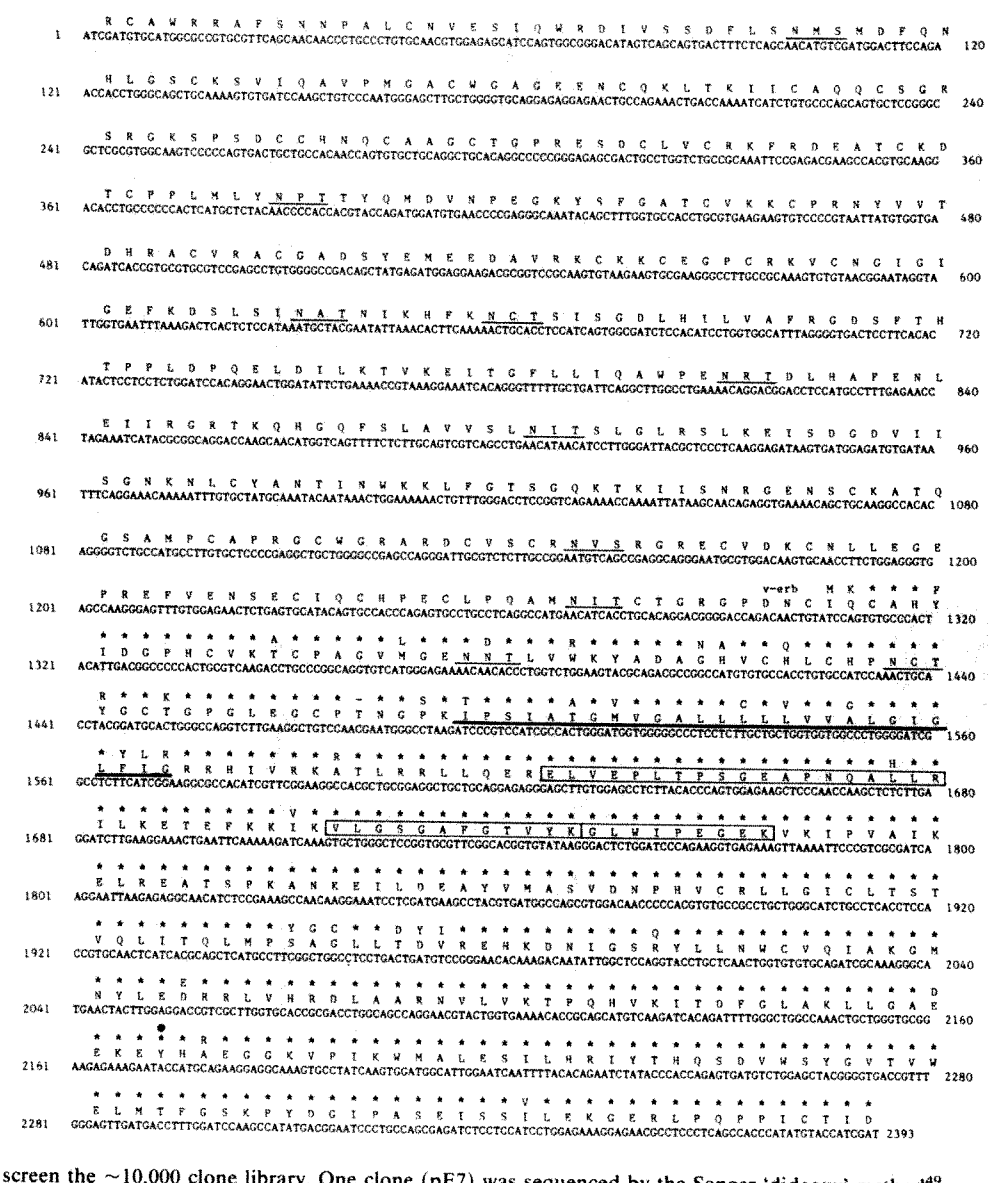

Fig. 1 Nucleotide sequence and deduced translation of the pE7 cDNA insert. The nucleotide sequence of the coding strand of pE7 is presented with the 5′-terminal *Cla*I site as position number 1. The amino acid sequence, represented by single-letter abbreviations, is shown directly above the DNA sequence. The translation of the v-*erb-B* (ref. 30) gene product is aligned with the pE7 translation and presented above it, beginning at nucleotide 1,305. Identical predicted amino acid sequences are indicated by asterisks (*). To optimize the similarities between two sequences, a nucleotide triplet has been removed at position 1,476, indicated by (—). Lightly underlined amino acid triplets represent potential *N*-linkage glycosylation sites, heavily underlined sequences indicate the location of the likely transmembrane region of the protein. A dot (•) points to the putative kinase phosphoacceptor[7,44]. Boxed sequences represent those amino acids shared with published EGF receptor peptide sequences[1]. The nucleotide sequence corresponding to the v-*erb-B* *Bam*HI fragment used to screen the library is located at 1,756–2,314.

Methods: Poly(A)$^+$ RNA was isolated from total A431 RNA[45] and used as a template for AMV reverse transcriptase synthesis of cDNA using oligo(dT) as primer[46,47]. After second strand synthesis[47], the cDNA was treated with S_1 nuclease (1 U μl^{-1}), blunt-end ligated to *Cla*I artificial linkers, restricted with *Cla*I, and after fractionation over Sepharose 4B to remove cDNA <500 bp, the cDNA was ligated into *Cla*I-digested pBR322 and cloned into *Escherichia coli* N38. A 0.5-kbp *Bam*HI v-*erb-B* fragment[30,31] was nick-translated[48] and used as probe to screen the ~10,000 clone library. One clone (pE7) was sequenced by the Sanger 'dideoxy' method[49]. The 2.4-kb insert was excised from pBR322 by restriction endonuclease cleavage with *Cla*I and purified by preparative electrophoresis on low melting point 1.0% agarose gels[50]. After further digestion with selected restriction endonucleases, fragments of the cDNA insert were ligated into the appropriate molecular cloning sites of bacteriophage M13 substrains mp-8–9, or –19 (ref. 51). After transfection into *E. coli* strain JM-101, single-stranded recombinant phage DNAs were isolated[52]. All DNA sequences were obtained by the dideoxy nucleotide chain termination method[49,52]. The single-stranded subclones were selected first at random and later by hybridization to overlapping fragments cloned in bacteriophage M13 in the opposite orientation. All M13 inserts were sequenced using a flanking universal primer[53]. The complete contiguous sequence was assembled from individual, overlapping subclones containing fragments in either orientation, using the programs described by Staden[54] modified to run on an IBM-3081 computer.

Here we report the isolation and characterization of cDNA clones obtained from an A431 cDNA library using a v-*erb-B* probe from the '*src* family' region that is known to be conserved among oncogenes[30,31]. The plasmid pEB1 containing the v-*erb-B* sequence was given by Dr Tadashi Yamamoto (University of Tokyo). Double-stranded cDNA synthesized using A431 poly(A)$^+$ RNA as template, was ligated to *Cla*I linkers and inserted into the *Cla*I site of pBR322. Out of the ~10,000 clones screened, six hybridized to a 0.5-kbp v-*erb-B* *Bam*HI fragment (pE3, 4, 5, 6, 7, 8). One of these clones (pE7) had a 2.4-kbp DNA insert flanked at both ends by *Cla*I restriction sites. A second (pE3) contained a 1.3-kbp DNA *Cla*I insert. Homology between pE7 and the other cloned cDNAs was demonstrated by hybridizing ^{32}P-labelled pE7 insert DNA to other blotted plasmid DNAs.

The sequence of the 2.4-kbp pE7 insert (Fig. 1) contains one open reading frame which converts to ~790 amino acids; the carboxy-terminus exhibits great homology to the v-*erb-B* protein sequence (Fig. 1), and limited similarity to RSV p60^{src} (ref. 30). In addition, three of the six EGF receptor peptides sequenced by Downward *et al.*[1] match exactly with the deduced amino acid sequence of pE7 (Fig. 1, boxed sequences). The other three are not contained in the 2.4-kbp insert because during the cloning of this DNA a natural *Cla*I site within the original cDNA molecule (now representing the 3′ end of the pE7 insert) was cleaved by *Cla*I before ligation into pBR322, thereby removing the extreme 3′ portion of the cDNA.

It is not yet clear whether the c-*erb-B* gene product and the EGF receptor are identical or simply related proteins. In principle, this pE7 cDNA clone could be derived from mRNAs encoding either the human c-*erb-B* gene product or the EGF receptor. We believe that pE7 codes for the EGF receptor because of the structural similarity between the pE7 deduced amino acid sequence and the EGF receptor peptides, and because RNA levels quantified by hybridization with pE7 correlate extremely well with EGF receptor protein levels in a variety of cell types (Y.-h.X. *et al.*, in preparation).

An interesting feature of the pE7 sequence is a hydrophobic stretch of 27 amino acids (Fig. 1, darkly underlined) of which 20 are nonpolar and 7 are neutral; this is probably the hydrophobic transmembrane region of the EGF receptor. The putative site for a phosphoacceptor is shown in the sequence (Fig. 1, tyrosine •). In addition, there are ten potential *N*-glycosidic linkage sites (Asn-Met-Ser; Asn-Pro-Thr; Asn-Ala-Thr; Asn-Cys-Thr; Asn-Arg-Thr; Asn-Ile-Thr; Asn-Val-Ser; Asn-Ile-Thr; Asn-Asn-Thr; Asn-Cys-Thr; Fig. 1, lightly underlined)[32,33] which could be involved in the complex glycosylation that occurs on the extracellular portion of the EGF receptor[34,35]. Mayes and Waterfield[36] have reported that biosynthesis of the human EGF receptor in A431 involves co-translational addition of at least seven *N*-linked oligosaccharide chains. It is possible that most or all of the potential sites derived from this cDNA sequence are used in EGF receptor processing.

The fact that there exists one full-length open reading frame suggests that this cDNA was synthesized from a single mRNA molecule, and not formed from a recombinational event between two different cDNAs in the same vector. The ability of the insert to be cut out of the vector cleanly by *Cla*I also supports the likelihood of a normal recombinant plasmid construction. To prove that this long cDNA was made from a single mRNA, R-looping was performed using *Sal*I-linearized pE7 (no sites in the insert) and A431 mRNA. Analysis of numerous R-loops revealed that the extreme 5′ end of the cDNA insert was consistently associated with RNA (long tail of pBR322); however, some variability in RNA hybridization was detected at the 3′ end (short tail of pBR322). The data suggest that at least two categories of RNA–DNA hybrids exist (see Fig. 2 legend). One type of RNA forms a full-length hybrid, with colinear homology over the entire span of the insert (Fig. 2*A*). Many of these full-length RNA–DNA structures have RNA tails at both ends, suggesting that a significantly longer RNA is responsible for the R-loop formation. This RNA probably

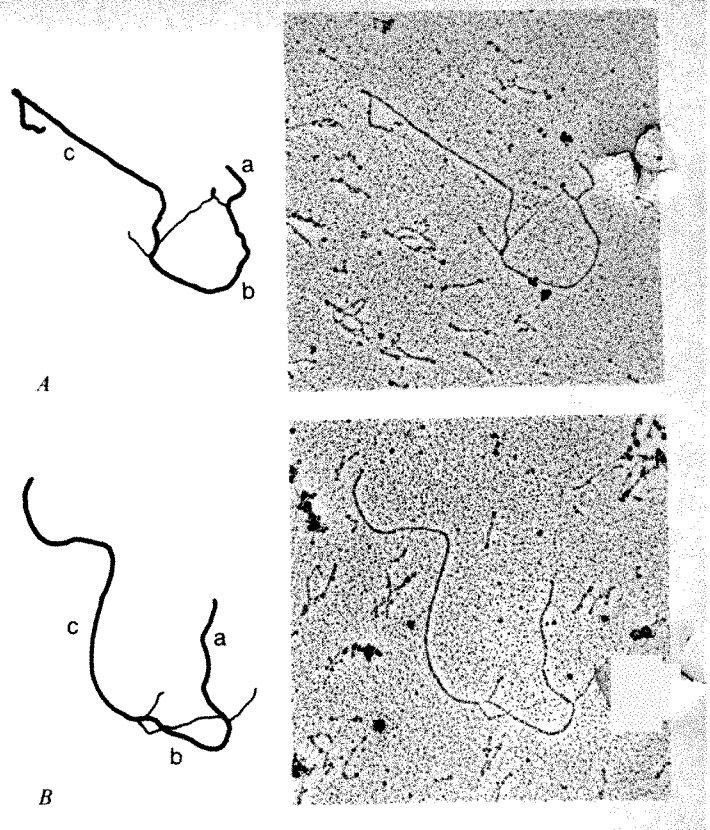

Fig. 2 R-loop analysis of pE7 using A431 poly(A)$^+$ RNA. Purified plasmid pE7 was linearized by *Sal*I digestion (cuts once in pE7 within the pBR322 portion), and hybridized with poly(A)$^+$ RNA. The hybrid molecules were spread and analysed[55]. a, Short arm of pBR322; b, RNA–DNA hybrid; c, long arm of pBR322. The thin strand in the b region represents the noncomplementary single-strand insert DNA. *A*, *B*, Representative molecules which fall into two classes of R-loops. *A*, The average size and standard deviation (in bp) of the sections represented by a, b and c are 646 ± 223, 1,673 ± 250, and 3,570 ± 415, respectively. Although only a 5′ RNA tail is seen in this R-loop, other R-loops showed tails at either the 3′ end, the 5′ end, or both. *B*, The average sizes are 1,312 ± 99, 1,293 ± 171 and 3,583 ± 294. ×16,000.

represents the normal EGF receptor mRNA, which would contain the coding region homologous with previously sequenced EGF receptor peptides, and which would have additional RNA regions extending beyond the cDNA insert at both ends of the molecule.

A second RNA forms an R-loop that is ~600 nucleotides shorter at the 3′ end (Fig. 2*B*). This structure, which also appears to have tails at both ends, is seen more often than the longer R-loop described above. The frequent appearance of the shorter RNA–DNA hybrid molecule suggests that a second RNA exists in A431 cells which has strong homology to the 5′ end of the pE7 insert, but not to the 3′ end.

If the 5′ end of the pE7 insert alone was capable of hybridizing to a different species of RNA, as suggested by the R-loop data, then Northern analysis using 3′- and 5′-specific pE7 cDNA fragments should confirm this. Messenger RNA was isolated from A431 and A498 cells (a human kidney carcinoma cell line which has about one-third the level of EGF receptors as A431; N. Richert and I.P., unpublished data), electrophoretically fractionated on 1% agarose, transferred to nitrocellulose, and hybridized to various cDNA probes. Figure 3 (lanes *a*) shows that the nick-translated 0.5-kbp *Bam*HI v-*erb-B* probe used to screen the cDNA library hybridizes to two prominent A431 RNAs of ~10 kb and 5.6 kb. Hybridization to A498 RNA gave a 4–5-fold less intense signal (Fig. 3*b*). Hybridization of the human pE7 probe to A431 RNA blots revealed a variety of

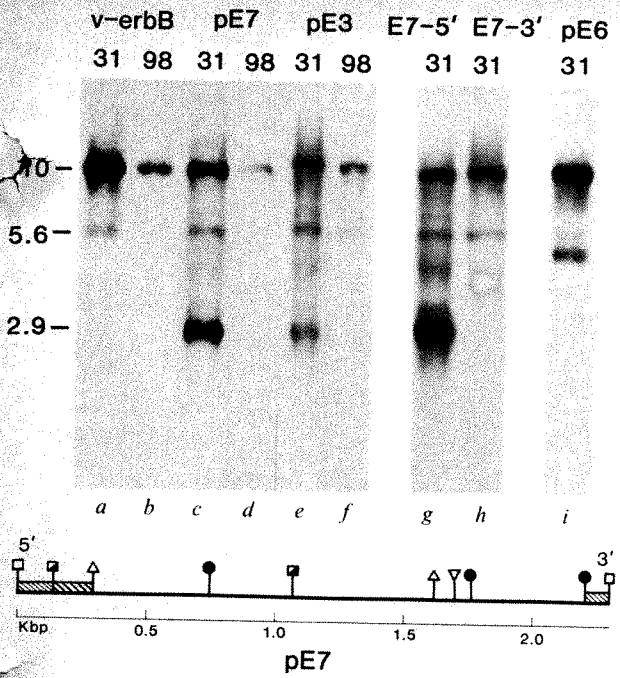

Fig. 3 Northern analysis of EGF receptor RNA. Poly(A)$^+$ RNA was isolated as described in Fig. 1 legend, either from A431 cells (31, lanes *a*, *c*, *e*, *g–i*) or A498 cells (98, lanes *b*, *d*, *f*), fractionated on 1% agarose, and transferred to nitrocellulose[56]. Nick-translated probes include the 0.5-kbp *Bam*HI v-*erb-B* fragment (lanes *a*, *b*);the 2.4-kbp cDNA insert from pE7 (lanes *c*, *d*); the 1.3-kbp insert of pE3 (lanes *e*, *f*); the 5′-specific *Cla*I-*Pst*I pE7 fragment (lane g); the 3′-specific *Bam*HI–*Cla*I pE7 fragment (lane *h*); and the 600-bp pE6 insert (lane *i*). Hybridization was in 50% formamide, 5×SSC at 42 °C for 36 h. Washing included 1 h in 0.2× SCC, 0.1% SDS at 45 °C. Numbers at the left indicate the size of the major RNA species in kilobases. Sizes were determined using rRNAs as markers, and the size of the 10 kb species is therefore an estimation. The restriction endonuclease map of the EGF receptor cDNA insert of pE7 is shown at the bottom. The region of pE7 corresponding to the v-*erb-B* 0.5-kbp probe is located approximately at the 1.75–2.25-kbp *Bam*HI–*Bam*HI fragment (see Fig. 1). The pE3 insert is located from ~1.0–2.3 kbp and the pE6 insert from 1.8 to 2.4 kbp on the map of pE7. The locations of fragments used for 5′- and 3′-specific hybridization are indicated by lined boxes. Restriction enzymes include *Cla*I (□), *Eco*RI (▽), *Pst*I (△), *Bam*HI (●) and *Pvu*II (◪). A more detailed restriction map is available from the authors on request.

RNAs, including the 10-kb and 5.6-kb species (Fig. 3*c*). In addition, three minor RNAs (6.3, 4.6 and 3.3 kb) and a prominent 2.9-kb species were found in the A431 cells. These RNAs were all present in elevated levels in A431 cells relative to A498 cells (Fig. 3*c*, *d*). This is consistent with the possibility that many, if not all, of the RNAs are related to the EGF receptor. It seems likely that these RNAs are generated by either complex splicing, or are transcribed from a gene family with multiple members localized on several chromosomes in A431 cells.

When the 1.3-kbp insert of pE3 was used as probe, the same RNAs were found (Fig. 3*e*, *f*). However, hybridization with a pE6 probe which contains a small ~600-bp cDNA insert homologous to the 3′ end of pE7 failed to visualize the 2.9- and 3.3-kb RNA species in A431 cells (Fig. 3*i*). The same result was obtained when a 90-bp fragment from the 3′ portion of the pE7 was used as a probe to hybridize to A431 RNA blots (Fig. 3*h*). However, a 290-bp fragment from the 5′ portion of pE7 hybridized to all the species detected by full-length pE7, including the 2.9- and 3.3-kb RNAs (Fig. 3*g*). The smaller 2.9-kb RNA is a relatively prominent species in A431 cells and is probably the species exhibiting great homology to ~1.5–1.6 kbp of the 5′ portion of the pE7 insert (R-loop analysis, Fig. 2*B*); it therefore could code for a truncated form of the EGF receptor. Recently, it has been reported that A431 cells secrete a truncated EGF receptor-like protein of the molecular weight 95,000–105,000 (refs 36, 37). This protein could be translated from a small A431 RNA (2.9 or 3.3 kb RNA). A 16-amino acid clostripain fragment of this truncated protein recently sequenced by Weber *et al.*[37] matches exactly with a stretch of amino acids deduced from clone pE7 at nucleotide positions 926–974 (Fig. 1). This region of the cDNA is homologous to the small RNA species as well as the large RNA (Figs 2, 3). These data confirm the close relationship between the truncated form and the full-length EGF receptor, and is consistent with the notion that one or both of the small RNAs encode the short receptor-like protein.

We recently reported that DNA sequences for the EGF receptor were amplified 30-fold and possibly rearranged in A431 cells[38]. Shimizu *et al.*[39] have reported that in addition to two normal chromosomes 7 that contain the EGF receptor gene, A431 cells contain two marker chromosomes (M4 and M14) originating from translocations between chromosome 7 and unidentified segments of DNA. One of these (M4) confers high EGF-binding capacity to fused A431/mouse A9 cells. These data raise the possibility that the 10-kb and/or the 5.6-kb RNA are transcribed from a normal EGF receptor gene on chromosome 7, and the 2.9-kb RNA species is transcribed from a chromosome involved in a rearrangement event at or near the location of the EGF receptor gene in A431 cells (possibly M4 and/or M14). However, a new RNA species could be generated by any gene disruption causing alterations in the normal start site, stop site, or patterns of RNA splicing. Whether or not this RNA encodes a protein which is responsible for the elevated EGF-binding ability of A431 cells remains to be established.

An additional interesting finding concerns heterogeneity between the different cDNA clones, as determined by restriction mapping and partial sequence analysis (data not shown). Further work is needed to determine whether this represents differential RNA splicing of an unprocessed EGF receptor gene product.

One striking characteristic of the EGF receptor gene is its similarity to the v-*erb-B* gene[1]. Because of the apparent functional relationship between growth factor receptors and oncogene products, it is interesting to compare our results for the EGF receptor with those involving other oncogene proteins. Transformed cells expressing high levels of either *myc* or *myb* protein were found to transcribe RNAs of unusual size, and to contain chromosomes involved in translocation events[40–43]. One possible explanation is that the overproduction of the 2.9-kb RNA and its corresponding modified protein product may be associated with the appearance of the malignant phenotype of A431 cells. To address this question, and to elucidate the nature of a putative EGF receptor gene rearrangement in A431 cells, we are now characterizing cDNA clones encoding the 2.9-kb RNA.

We thank Catherine McKeon, John Fagan, John Hanover, Nancy Richert, Azriel Schmidt, Rudi Pozzatti, Bruce Howard, Maria Mudryj and Doug Hanahan for their advice or for reading this manuscript; Betty Lovelace, Annie Harris and Raji Padmanabhan for cell culture work; Ray Steinberg for photography; and Ann Schombert for typing the manuscript. We are indebted to Tadashi Yamamoto for the avian v-*erb-B* plasmid pEB1. B.A.R. was supported in part by NIH grant GM30400.

Note added in proof: Since submitting this paper, two reports[57,58] reaching essentially the same conclusions, have been published.

Generation of β-globin by sequence-specific proteolysis of a hybrid protein produced in *Escherichia coli*

Kiyoshi Nagai & Hans Christian Thøgersen

Laboratory of Molecular Biology, Medical Research Council Centre, Hills Road, Cambridge CB2 2QH, UK

High-level expression of many eukaryotic genes has proved difficult to achieve even when a strong promoter[1–3] and the ribosome binding sequence[4,5] from highly expressed *Escherichia coli* genes have been placed in front of the coding sequences. To overcome this problem, many eukaryotic proteins have been efficiently produced as hybrids after fusion of their genes with a coding sequence of *E. coli* genes[6]. However, such hybrid proteins are not suitable for functional studies or clinical use unless the authentic protein sequence can be released by specific cleavage. Here, we have inserted the sequence Ile-Glu-Gly-Arg between the 31 amino-terminal residues of λ *c*II protein and Val 1 of human β-globin, and produced this hybrid in high yield in *E. coli*. We then cleaved the hybrid specifically at the single arginine, using blood coagulation factor X_a and thus liberated the authentic β-globin chain. As factor X_a is specific for the tetrapeptide Ile-Glu-Gly-Arg[7], which is rare in protein sequences, our expression/cleavage system is applicable to the efficient production of many eukaryotic proteins.

Table 1 Peptide bonds known to be cleaved by blood coagulation factor X_a

P_4	P_3	P_2	P_1		P'_1	P'_2	P'_3	P'_4	Substrate
Ile	Glu	Gly	Arg	=	Val	His	Leu	Thr	*c*IIFXβ-globin
Ile	Glu	Gly	Arg	=	Thr	Ala	Thr	Ser	Human prothrombin[15,16]
Ile	Glu	Gly	Arg	=	Thr	Ser	Glu	Asp	Bovine prothrombin* (ref. 7)
Ile	Asp	Gly	Arg	=	Ile	Val	Glu	Gly	Human prothrombin[16]
Ile	Glu	Gly	Arg	=	Ile	Val	Glu	Gly	Bovine prothrombin* (ref. 7)
Ala	Glu	Gly	Arg	=	Asp	Asp	Leu	Tyr	Human antithrombin III[17]

Proteolytic cleavage by blood coagulation factor X_a occurs between P_1 and P'_1 sites.

* Factor X_a cleaves identically both native prothrombin and its chymotryptic peptides containing these peptide segments.

We first constructed a new expression vector, pLcIIβ, which directs synthesis of a hybrid protein consisting of the 31 amino-terminal residues of λ *c*II protein and the complete β-globin chain under the control of the λ P_L promoter (Fig. 1*b*). A secondary structure near the ribosome binding sequence should be retained even after the β-globin gene has been fused and should provide high translational efficiency. The control plasmid pLcII is identical to pLcIIβ, except that it contains a sequence with multiple restriction sites instead of the β-globin gene insert. When MZ-1 cells (a defective λ lysogenic strain) harbouring pLcIIβ are grown at 30 °C, the *c*I857 temperature-sensitive repressor is active and hence transcription from the P_L promoter is fully repressed[8,9], but at 42 °C the *c*IIβ-globin gene is efficiently transcribed. Figure 2 shows a Coomassie blue-stained polyacrylamide gel of total cellular proteins from cultures with and without heat induction. After heat induction, a new intense band appeared for MZ-1 cells harbouring pLcIIβ. The band co-migrated with soybean trypsin inhibitor consisting of 181 amino acid residues, the same number as in the *c*IIβ-globin hybrid. Western blot experiments[10] showed that the new band, as well as natural human β-globin, reacted with ^{125}I-labelled goat anti-rabbit β-globin IgG (data not shown), indicating that the new band is the *c*IIβ-globin hybrid.

In a second stage, we inserted a short oligonucleotide between the λ *c*II and β-globin genes of pLcIIβ to form pLcIIFXβ, so that the first codon (Val) of the β-globin gene was preceded by a sequence encoding the tetrapeptide: Ile-Glu-Gly-Arg (Fig. 1*b*). This is the sequence that immediately precedes the two factor X_a cleavage sites in prothrombin[7]. The hybrid protein, designated *c*IIFXβ-globin, was purified from MZ-1 cells harbouring pLcIIFXβ and digested with blood coagulation factor X_a which had been activated with Russell's viper venom[11]. Digestion was complete within 2 h at a molar ratio of enzyme to substrate of ~1:100. No further cleavage occurred, except for a slow proteolysis by *E. coli* enzymes which occurred even in the absence of factor X_a. The new band that appeared after factor X_a digestion co-migrated with the slower band of haemoglobin corresponding to the β-chain (Fig. 3). In contrast, the *c*IIβ-globin protein which lacks the tetrapeptide insert remained uncleaved by factor X_a. Reverse-phase HPLC of tryptic peptides confirmed that the product of factor X_a digestion of *c*IIFXβ-globin is identical to natural β-globin (data not shown). Cleavage of the *c*IIFXβ-globin protein by factor X_a occurred exclusively at the peptide bond following Ile-Glu-Gly-Arg, even though the hybrid protein contained 6 other arginyl and 14 lysyl residues. In the same conditions trypsin cleaves β-globin at every peptide bond following arginine and lysine, thus the absence of such cleavage by coagulation factor X_a cannot be due to inaccessibility of the substrate. Moreover, the enzyme

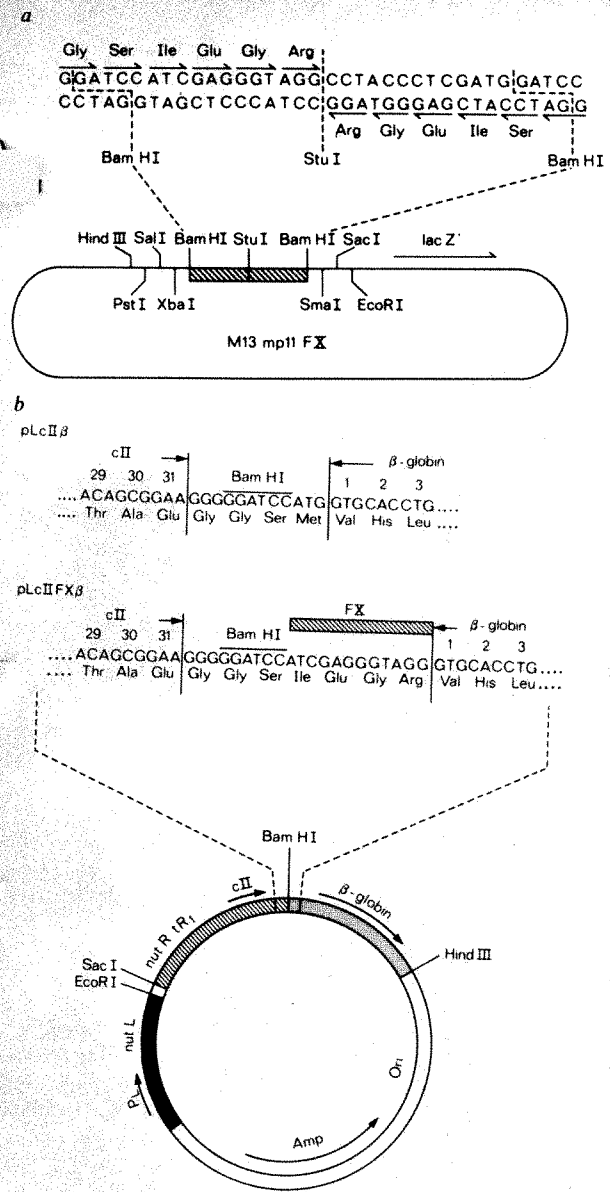

Fig. 1 Construction of M13mp11 FX and pLcIIFXβ. *a*, M13mp11 FX contains a sequence encoding the recognition site for factor X_a. This M13 derivative can be used to join any coding sequence to the factor X_a recognition sequence. *b*, pLcIIFXβ and pLcIIβ direct efficient production of a hybrid protein consisting of the 31 amino-terminal residues of the λ *c*II protein and the complete human β-globin, with and without the factor X_a cleavage site, respectively.

Methods: All DNA manipulations were essentially as described elsewhere[18]. A temperature-sensitive lysogenic strain MZ-1 (*gal*K_{am}Δ*8att*LΔ*Bam*N_7N_{53}*c*I857ΔH1, *his*$^-$, *ilv*$^-$, *bio*$^-$, N^+, given by Dr K. McKenney) was used as a host strain for plasmids containing the λ P_L promoter and transformation was done as described by Remaut *et al.*[8]. T4 DNA ligase was prepared from strain NM989 (refs 19, 20). Restriction enzymes were from New England BioLabs. *a*, M13mp11 FX: Two oligonucleotides, dTACCCTCGATGGATC and dCATCGAGGGTAGGCC, were synthesized by a phosphotriester method on a controlled pore glass support[21] and purified by HPLC[22]. The two oligonucleotides were allowed to anneal after phosphorylation with T4 polynucleotide kinase (P-L Biochemicals) and r[γ-^{32}P]ATP (3,000 Ci mmol^{-1}; Amersham) and ligated to form concatamers. The DNA was then digested with *Bam*HI and cloned into the dephosphorylated *Bam*HI site of M13mp11 (ref. 23) to yield M13mp11 FX which forms blue plaques in the presence of isopropyl-β-D-thiogalactopyranoside and 5-bromo-4-chloro-3-indolyl-β-D-galactoside (Sigma). *b*, Construction of pLcIIβ and pLcIIFXβ: The *Eco*RI–*Hin*dIII fragment containing the multi-restriction sites was cut out from M13mp10 (ref. 23) and ligated to *Eco*RI–*Hin*dIII-cut pLc245 (ref. 8) to form pLmp10. The 319-base pair (bp) *Alu*I fragment containing the *nutR*, t_{R1} sites[3] and a part of the *c*II gene was cut out from pKG1805 (ref. 24) and cloned into the *Sma*I site of M13mp10 in the same orientation with respect to the β-galactosidase α-peptide gene. The *Eco*RI–*Hin*dIII fragment containing the λ DNA sequence was then cut out and cloned into the *Eco*RI–*Hin*dIII site of pLmp10 to yield pLcII. A complete human β-globin cDNA sequence was reconstructed by joining restriction fragments prepared from an incomplete cDNA clone (pJW102)[25] and a genomic DNA clone[26], and this was cloned into the *Sma*I–*Hin*dIII site in M13mp9. The M13mp9 β cDNA thus obtained was opened at the *Nco*I site, which is located at the initiation codon, and treated with Klenow DNA polymerase (Boehringer Mannheim) in the presence of 100 μM 4dNTP to obtain flush ends. The β-globin cDNA sequence was then cut out with *Hin*dIII and inserted into the *Bam*HI (filled-in)–*Hin*dIII site of pLcII so that the β-globin gene was fused to the λ *c*II gene in-phase via a small linker DNA derived from M13mp10. To construct pLcIIFXβ, M13mp9 β cDNA was opened with *Nco*I and 40 μg of DNA were treated with 200 U of mung bean nuclease (P-L Biochemicals) in 30 mM Na-acetate *p*H 4.6, 50 mM NaCl, 1 mM $ZnCl_2$, 5% glycerol at 0 °C for 10 min to remove the 5′ protruding end. The β-globin cDNA sequence was cut out with *Hin*dIII and cloned into the *Stu*I–*Hin*dIII-cut M13mp11 FX. The DNA sequence was determined by the dideoxy chain termination method[27] to ensure that the first valine codon of the β-globin gene was preceded by the DNA sequence coding for Ile-Glu-Gly-Arg. Then, the *Bam*HI fragment containing a part of the β-globin sequence was cut out and cloned into *Bam*HI-digested pLcIIβ to form pLcIIFXβ.

does not require the three-dimensional structure of the substrate to be intact, as it cleaves the recognition sequences in both native prothrombin and in two chymotryptic prothrombin peptides[7]; this shows that it is strictly sequence-specific.

All the polypeptides cleaved by factor X_a contain arginine and glycine at the P_1 and P_2 sites, respectively, and the P_3 site is occupied by a negatively charged residue—glutamic acid or aspartic acid (Table 1). As the peptide bond following Leu-Gly-Arg in *c*IIFXβ-globin is not cleaved by factor X_a, a Glu-Gly-Arg or an Asp-Gly-Arg sequence seems to be a minimal requirement for cleavage. The requirement for the P_4 site is not yet clear, but the present limited data suggest that it must be occupied by a hydrophobic residue. Table 1, together with the data for other trypsin-like serine proteases, shows that the P'_1 site can be occupied by a variety of amino acid residues, including a large aliphatic one, a positively charged one or a negatively charged one. On the other hand, trypsin-like proteases do not cleave peptide bonds preceding proline. Therefore, factor X_a will cleave any peptide bond preceded by Ile-Glu-Gly-Arg or Ile-Asp-Gly-Arg, unless proline occupies the P'_1 site, and may be regarded as a 'restriction endopeptidase'. Several short eukaryotic polypeptides have been liberated from hybrid proteins by trypsin or cyanogen bromide, but such methods[6,12,13] cleave proteins like β-globin at several arginines and lysines or at several methionines.

In our expression/cleavage system the bacterial leader sequence provides a high translational efficiency while the factor X_a cleavage eliminates the extra amino-terminal methionine encoded by the initiation codon which is present in most eukaryotic proteins expressed in *E. coli* by conventional methods[6]. The pro-enzyme, factor X, is readily prepared from bovine blood plasma with a yield of 5 mg l^{-1}. Factor X is isolated biochemically pure and free from contaminating proteases after adsorption from plasma on insoluble barium salts, followed by one chromatographic step[14]. For the construction of other hybrid protein expression vectors, any blunt-ended coding sequence can be cloned into the *Stu*I site of M13mp11 FX which contains a sequence encoding the factor X_a recognition site (Fig. 1*a*). The gene, together with the factor X_a recognition sequence, can then be cut out from the M13 clone with *Bam*HI and cloned into the *Bam*HI site of pLcII, or indeed any hybrid protein expression system, so that the cleavable hybrid protein can be produced. This method is now being applied, in our laboratory, to the production in *E. coli* of several eukaryotic proteins.

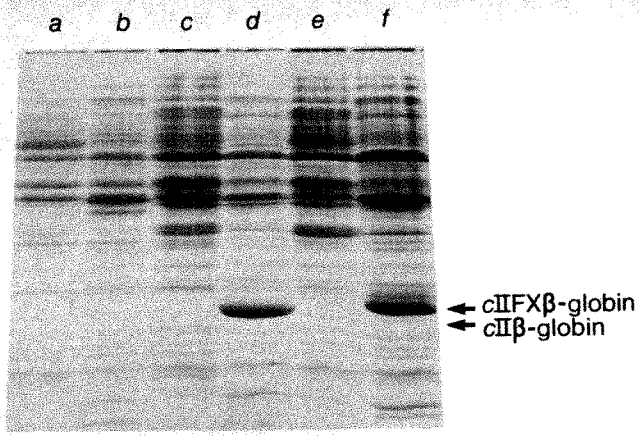

Fig. 2 Expression of *c*IIβ-globin hybrid protein in *E. coli*. Total cellular proteins from MZ-1 carrying pLcII, pLcIIβ and pLcIIFXβ, with and without 2 h of heat induction, were analysed on an 18% polyacrylamide-SDS gel and visualized with Coomassie blue. *a*, pLcII at 30 °C; *b*, pLcII at 42 °C; *c*, pLcIIβ at 30 °C; *d*, pLcIIβ at 42 °C; *e*, pLcIIFXβ at 30 °C; *f*, pLcIIFXβ at 42 °C. **Methods:** MZ-1 cells harbouring the expression plasmids pLcII, pLcIIβ and pLcIIFXβ were grown to $A_{600} = 0.7$ in 2 × TY medium (16 g Tryptone, 10 g yeast extract, 5 g l^{-1} NaCl) at 30 °C and for each of the cultures, one half was mixed with an equal volume of 2 × TY preheated to 65 °C and grown at 42 °C. The other half was grown further at 30 °C as a control. The total cellular protein was extracted with an equal volume of phenol and spun down after precipitation with 5 vol. ethanol[8]. The pellet was dissolved in SDS sample buffer and analysed on an 18% polyacrylamide-SDS gel[28].

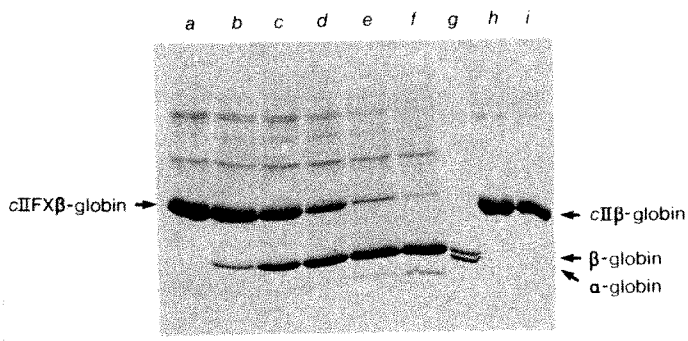

Fig. 3 Digestion of *c*IIFXβ-globin protein with bovine blood coagulation factor X_a. The *c*IIFXβ-globin hybrid protein was digested with factor X_a at an enzyme to substrate molar ratio of 1 : 100 at 25 °C and analysed on an 18% polyacrylamide-SDS gel[28]. *a*, Undigested *c*IIFXβ-globin; *b*, 5 min; *c*, 15 min; *d*, 30 min; *e*, 60 min; *f*, 120 min after addition of factor X_a; *g*, human adult haemoglobin comprising the α (faster band) and β (slower band) chains. The *c*IIβ-globin hybrid protein which lacks the cleavage site for factor X_a was treated with factor X_a in the same conditions: *h*, after 120 min of treatment; *i*, untreated *c*IIβ-globin. **Methods:** MZ-1 cells harbouring pLcIIFXβ were grown in 500 ml of 2 × TY medium. At $A_{600} = 0.7$, the culture was mixed with 500 ml of 2 × TY preheated to 65 °C, then grown at 42 °C. After 2 h, cells were collected, and the high salt precipitate was prepared[29]. The pellet was dissolved in 30 ml of 10 mM Na-phosphate *p*H 6.4, 1% SDS (BDH), 1% β-mercaptoethanol and incubated in a boiling water bath for 5 min. The sample was dialysed against 10 mM Na-phosphate *p*H 6.0, 1 mM dithiothreitol, 0.1% SDS and purified on a hydroxylapatite (Bio-Rad, DNA grade) column[30]. The *c*IIFXβ-globin hybrid protein was concentrated by ultrafiltration (Amicon, PM-10 membrane) then precipitated with 6 vol. acetone/0.1 M HCl to remove SDS. The precipitate was air-dried, dissolved in a minimal amount of 8 M urea, 50 mM Tris-HCl *p*H 8.0 and dialysed against 100 mM NaCl, 50 mM Tris-HCl *p*H 8.0 and 1 mM $CaCl_2$. Bovine blood coagulation factor X (given by Dr M. P. Esnouf) was activated to factor X_a with Russell's viper venom (Sigma)[11].

We thank Dr M. F. Perutz for suggesting this project; Drs K. McKenney, S. Anderson and S. Brenner for many helpful suggestions; Dr D. M. Brown for help with the oligonucleotide synthesis; Dr A. Klug for criticism; Drs M. P. Esnouf, E. Remaut, K. McKenney, M. Rosenberg, K. D. Smith, J. Clegg, J. V. Kilmartin and B. S. Sproat for essential materials; a[illegible]r Y. Enoki for encouragement. K.N. was supported by a T[illegible]s Usher Fellowship and recently by NIH grant RO1 HL 31[illegible]. H.C.T. was supported by an EMBO long-term fellowship. This paper is dedicated to Max Perutz on the occasion of his 70th birthday.

Erratum

Expression and amplification of the N-*myc* gene in primary retinoblastoma

W.-H. Lee, A. L. Murphree & W. F. Benedict
Nature **309**, 458–460 (1984).

THE first paragraph on page 460 was printed incorrectly. It should read: 'amplification in neuroblastoma and N-*myc* expression in the retinoblastoma strongly suggests that the N-*myc* gene may belong to the proto-oncogene family. The fact that the N-*myc* gene is amplified and expressed in both retinoblastoma and neuroblastoma is of obvious interest. This is especially so because both tumours originate from neural crest ectodermal cells, although retinoblastoma may develop from a more primitive cell than neuroblastoma[22]. However, we have no evidence to exclude the possibility that genes other than N-*myc* are involved in these two types of tumour formation.'

PRENATAL DIAGNOSIS

Proceedings of the Eleventh Study Group of the Royal College of Obstetricians and Gynaecologists

edited by **C.H. Rodeck** and **K.H. Nicolaides**

Each year the Royal College of Obstetricians and Gynaecologists convenes a study group which examines in detail one particular aspect of obstetrics and gynaecology. Last year's subject was prenatal diagnosis, and this book is a co-publication of the Proceedings by Wiley and the RCOG. The study group consisted of a small number of international experts in the field who discussed the topical issues in prenatal diagnosis such as techniques and methods, chromosome anomalies, Mendelian recessive disorders, X-linked disorders and multifactorial malformations. The book will be an invaluable source of up to date information on the state of current knowledge.

0471 90500 3 414 pages April 1984 £16.50

A Co-publication with Royal College of Obstetricians and Gynaecologists.

CONTROLLED DRUG BIOAVAILABILITY

Volume 1: Drug Product Design and Performance

edited by **V.F. Smolen,** *PharmaControl Corporation, Englewood Cliffs, New Jersey;* **L-A Ball,** *University of Pittsburgh*

This is the first volume of a continuing series of monographs covering drug delivery systems designed to provide maximum therapeutic benefits. It provides state-of-the-art guidance in the development of these delivery systems.

Series: Controlled Drug Bioavailability

0471 05732 0 312 pages June 1984 £64.35

CLINICAL ATLAS OF HUMAN CHROMOSOMES, 2nd Edition

by **J. de Grouchy** and **C. Turleau,** *both of Hospital Necker, Paris*

This is a comprehensive discussion by a leading international authority on cytogenetics. The new Second Edition reflects the many important changes that have occurred in the field over the past five years. Included are forty new syndromes, an updated presentation of cytogenetic techniques and the gene map, and a new chapter on types and mechanisms of chromosome arrangements.

0471 89205 X 508 pages May 1984 £56.50

THE KIDNEY Diagnosis and Management

edited by **N.S. Bricker** and **M.A. Kirschenbaum,** *both of UCLA School of Medicine, Los Angeles*

This is a comprehensive text/reference covering all aspects of nephrology from clinical evaluation to practical management of kidney disease and disorders to body fluids. It includes the latest diagnosis and treatment therapies and treats major areas of acute renal failure, cancer, radiologic evaluation, and nutrition.

0471 09572 9 560 pages February 1984 £31.95

CYSTIC FIBROSIS: HORIZONS

Proceedings of the 9th International Cystic Fibrosis Congress, Brighton, England, June 9th-15th, 1984

edited by **D. Lawson,** *Cystic Fibrosis Research Trust, Bromley, Kent*

The Cystic Fibrosis Research Trust, London, hosted the 9th International CF Congress in Brighton in June 1984 on behalf of the ICF (M) A. Scientists and clinicians from all over the world presented their findings on important aspects of CF research and patient care, with the main themes being prenatal diagnosis and carrier detection, biochemical problems, the changing management of CF, and the search for the basic defect. Fundamental scientific issues were discussed, as well as the clinical management of the disease. This volume contains the invited speakers' contributions, each of which is an authoritative presentation of the current state of knowledge in each field. All other contributions, whether oral or poster presentations, are included in the book in abstract form.

0471 90439 2 400 pages May 1984 £15.00

A GUIDE TO THE CHEMICAL BASIS OF DRUG DESIGN

by **A. Burger,** *University of Virginia*

This deals with the chemical structure of biologically active compounds used in the field of medicinal chemistry. It examines what is known about advanced drug design. It presents a unique historical overview of drug discovery and design using the historical facts of the pharmacology to reveal the serendipity of discovery and to point toward new structures that may be developed based on what has gone before.

0471 86828 0 312 pages November 1983 £38.35

MEDICAL COMPLICATIONS OF MALIGNANCY

edited by **F.E. Smith** and **M. Lane,** *both of Baylor College of Medicine, Houston*

This study of cancer is unique in its approach to the subject by organ system. Extensive illustrations provide an atlas style that is easy to use. It considers psychological issues, and long range and palleative care.

0471 04362 1 288 pages June 1984 £28.00

CURRENT NEPHROLOGY, Volume 7

by **H.C. Gonick,** *UCLA School of Medicine*

This is a thoughtful series of contributions by medical experts on the current methods for overcoming the immunological barriers to transplantation, pointing out their flaws, their strengths, and highlighting those advances that have been made.

Series: Current Nephrology, Volume 7

0471 88992 X 606 pages February 1984 £64.05

Science for sale

Dorothy Nelkin

The New Politics of Science. By David Dickson.
Pantheon, New York: 1984. Pp.374. $22.95.

THAT knowledge is power has been well understood and much discussed in many analyses of the politics of science. In *The New Politics of Science*, David Dickson describes the new dimensions of this truism in the 1980s, arguing that science today is a commodity, a policy instrument, a source of legitimation, a basis of imperialism in foreign policy, and a form of property that is being manipulated according to the needs of the military, the marketplace and the private sector. It is a provocative book. Dickson, the European correspondent for the journal *Science*, first characterizes a set of systematic and interrelated changes in American policies concerning science and technology. He then turns to their implications for the nature of scientific research and structure of universities and, more important, to their influence on the relationship between the citizen and the state.

Dickson argues that science is increasingly used to reinforce the concentration of political power in the hands of those who dominate the economy. Tracing the development of patterns of control over science during different historical periods, he concludes that recent changes, reflecting an "almost religious belief in the power of science-based technology", are dramatic and potentially pernicious. Indeed, he has written this book with the openly political purpose of revealing the problematic political and social consequences of recent changes in science and technology policy in the United States. Because of his concentration upon the influence of capitalism, some may interpret the book as merely a diatribe from the left. It is not. Rather, Dickson is pointing to a set of pressures which, taken together, indicate sweeping structural changes in the politics of science.

Dickson's foremost worry is that decisions about both the allocation of scientific resources and the application of scientific results are increasingly concentrated in the hands of corporate banking and military leaders who have gained the willing cooperation of scientific, governmental and academic institutions. He describes how the demands of the private sector influence government research policy and leave social objectives (such as protection of the environment) as issues secondary to the profitability of private corporations. He follows the changing character of budgetary decisions as science is increasingly viewed as "knowledge capital" expected to generate an appropriate return. And he suggests that unfettered technological development is endorsed in order "to get the economy back on its feet", with little attention being paid to its social consequences.

Dickson documents three striking manifestations of the changing politics of science. First are the new relationships between industry and academia that have developed with the renewed commercial interest in basic research. Knowledge, argues Dickson, is a "commodity", a form of "real estate". The result is that the public resources that universities represent are increasingly placed at the service of private capital.

Second, Dickson turns to the renewed links between the American scientific community and the military establishment, as reflected both in changing patterns of military funding of academic research and in growing security controls. Tracing the increased influence of the military in academia since the 1970s, he calls attention to the ironies of scientists accepting — and indeed soliciting — military support while worrying about controls on open communication as the government seeks to limit the transfer of technological information in the interests of national security.

Third, through numerous examples, he points to the growing foreign policy implications of science and technology, given their importance in international economics. Influenced by multi-national corporations, Third World politics are especially vulnerable to policies that are determined by profit rather than need. So too are international agreements such as the Law of the Sea.

Dickson finds it notable that today's politics of science developed after a decade of challenge and introspection during which many people, through the environmental and consumer movements, questioned the definition of "progress" and insisted that science and technology must serve the needs of society rather than determine those needs. That period of protest revealed two conflicting approaches to the politics of science based on "democratic" and "technocratic" strategies. The technocratic approach called for "rational" solutions to the problems of technology through a consensus of experts; the democratic strategy looked towards redistribution of political power through greater public involvement in technological decisions.

For a brief period, demands for increased democratic control over technology appeared to be influencing the politics of science and technology as public agencies groped for assessment procedures that would involve citizens in general. The new politics of science represents a powerful counter-attack against such reforms. Today, Dickson argues, technocratic strategies prevail as technical and economic decision-making methodologies are used to cloak political judgements in the garb of scientific neutrality; and scientific arguments are used to dismiss challenges from concerned citizens. In effect, science has become a policy instrument reinforcing the ascendance of technocratic over democratic values and reducing political choice.

What are the consequences of the new politics? Dickson sees a declining interest in the environmental, social and ethical implications of research. And as criteria of efficiency replace the emphasis on equity, he sees a re-direction of research away from social priorities. He also discerns changes within the community of science as commercial and military interests lead to secrecy and to tensions over traditional patterns of scientific communication. He worries about relationships within universities as certain departments compete to keep their faculty together in the face of well-paid entrepreneurial temptations. But, above all, Dickson worries about the political consequences of the new politics of science — the reduced possibilities for public involvement in political decision-making and the increased deference to technical expertise. Indeed, he sees the future of democracy itself as being at stake.

Dickson's argument is supported by many case-histories and placed in perspective with historical comparisons. While he is convincing, he also raises a number of unanswered questions. How did such dramatic political changes take place so quickly with so little public response? Why are academic scientists, who only a decade ago were widely disenchanted by university–military relationships, so quick to renew those relationships today? Why are campuses and grass-roots movements, until recently mobilized around related issues (military research in universities and the environmental and social effects of technical change), now so apathetic? How have the actors involved in the new politics of science cultivated the public apathy that has allowed uncritical deference to technocratic expertise? Dickson says too little about the media as a vehicle for gaining public consent for the new politics of science, and does little to explain the pressures within science that foster changing attitudes.

Dickson is by no means anti-science or opposed to technological change. Rather, he wants to re-integrate public needs and aspirations into science policy, to shift the priorities of science and technology away from destructive ends (such as defence) and

towards socially constructive goals (such as better health or nutrition). He concludes with some general proposals. He would like to democratize procedures within the scientific community so that priorities and practices would be open for broader public discussion; he would like to change the institutions responsible for allocating research funds to allow greater public input; he wants to develop ways of democratizing technological innovation to ensure that considerations of equity influence production; and he wants to maintain public access to the fruits of publicly funded research.

Dickson ends his book on a bizarre note, by taking encouragement from the effectiveness of the Creationists in challenging scientific ideas. In my view, he misinterprets the significance of Creationism. Far from creating a "political program that includes a vision of an alternative science", this group has manipulated the populist tendencies of American Fundamentalists to enhance the power of a small religious group. Yet this conclusion to the book should not divert the reader from its very positive, indeed Utopian message — that science, one of the greatest cultural and intellectual achievements of the modern age, must be shaped in accordance with democratic values in order to enhance the public good. □

Metallic electrons

Michael Springford

Magnetic Oscillations in Metals.
By D. Shoenberg.
Cambridge University Press: 1984. Pp.570. £55, $97.50.

OCCASIONALLY a book appears of which it may be said that the author, the content and the timing could not be bettered. *Magnetic Oscillations in Metals* by Professor David Shoenberg is just such a book.

It was in 1932, at the suggestion of Kapitza, that the author, then a new graduate student at the Royal Society Mond Laboratory in Cambridge, was introduced to the mysterious magnetic properties of bismuth. Only a few years previously, in Leiden, de Haas and van Alphen had observed magnetic oscillations in this metal at low temperatures. The oscillations of the magnetization as the magnetic field was varied were thought at first to be peculiar to bismuth, but in time they were understood to be a fundamental property of all metals.

In a historical introduction, Shoenberg charts the course of the development of the de Haas–van Alphen effect, as it came to be called, from a curiosity to arguably the single most important experiment in solid state physics. We read of the insights of Landau on the origin of the effect, of the unexpected success of the nearly free electron model as crucial evidence in the development of pseudopotential theory, and of the subtle and fruitful interplay over the years between experiment and theory. The influence exerted on the course of solid state physics by studies of magnetic oscillations originated in large measure from their versatility and accuracy. Band theoretic methods, for example, could be fine-tuned and became more useful and reliable instruments in other fields. For more than half-a-century, in events from which the author has seldom been far removed, magnetic oscillations have been employed as a spectrometer for the investigation of electrons in metals. It is with these many aspects of the field that the book is principally concerned.

An objective early in the book is to expound the theory of magnetic oscillations, broadly along the lines first set out by Lifshitz and Kosevich in 1955, use being made of the now-familiar geometrical interpretation of electronic properties for the physical insight it provides. The theory is developed for both two- and three-dimensional systems, with the more cumbersome mathematical results being helpfully placed in appendices. Given the historical development of the subject it is proper that the determination of Fermi surfaces (Fermiology), should have a prominent place. Here Shoenberg concentrates more on general principles, following this with a survey of what has been accomplished in a few selected metals. For a more encyclopaedic approach the reader is referred elsewhere.

In later chapters, attention is focused on more contemporary topics where, in characteristic style, the author does not fail to highlight areas where uncertainties remain, such as the effect of dislocations upon magnetic oscillations, nor those, such as the influence of many-body interactions, where even the general principles involved are still very much in question.

Although the study of magnetic oscillations has reached maturity as an established branch of solid state physics, this is remarkably the first book to be devoted to a complete exposition of the subject. Work on magnetic oscillations is still actively pursued and the author believes that this will continue for a long time yet. So too will his book remain the definitive text for research workers in this field. □

Michael Springford is Professor of Experimental Physics at the University of Sussex.

Cultural influence

Paula Brown Glick

Ruth Benedict: Patterns of a Life.
By Judith Modell.
Chatto & Windus/University of Pennsylvania Press: 1984. Pp.355. Hbk £15, $30; pbk $11.95.

RUTH BENEDICT (1887–1948) has occupied an important place in the history of American anthropology for the past 50 years, ever since the publication of *Patterns of Culture* in 1934. Judith Modell, the author of this biography, is herself an anthropologist and quite clearly feels a strong personal identification with her subject. Yet she does not attempt to evaluate Benedict's scholarship or contribution to anthropology.

The biographer is able to cite Ruth Benedict's published and unpublished writings — poems, notebooks, letters and an autobiographical fragment written in 1935 — in her examination of Benedict's childhood and youth. But now, over 30 years after Benedict's death, recollections culled from friends, relatives and students do not fully satisfy inquiry — many questions remain. From the characterization of Stanley Benedict, her husband, and of some close friends, the figures remain shadowy; here the reader must accept the limitations of the biographer's materials. Modell has attempted to discern the pattern of Benedict's life, and has certainly laid out the whole sweep of her person and her interests, as child and adult, in literature and anthropology. The influence of philosophical and religious thought upon Benedict is not fully examined, however; her feminism is muted. And a chapter on her anthropological work was evidently unduly influenced by Margaret Mead's books about Benedict, and seems uncritically repetitive.

Ruth Benedict was a student of Franz Boas of Columbia University, who has been called the "builder and architect of modern anthropology" and who built the Anthropology Department at Columbia University into a centre for anthropology, ethnography and folklore study. Ruth Benedict entered this realm in 1921, in her thirties, there finding a personal role, a purpose for her life and a new subject for writing. She visited American Indian settlements to record texts and cultural data from informants — the usual method of American anthropologists of the time — and was Boas's closest assistant for 20 years, teaching and supervising students

- *Darwin and His Critics* by David L. Hull. (University of Chicago Press, $15, £12.75.) For review see *Nature* **248**, 285; 1974.

although she had no permanent academic position at Columbia.

Boas's women students, especially Margaret Mead and Ruth Benedict, became widely known to American students and scholars in fields far beyond the small group of cultural anthropologists of the time. While Mead married and made many field trips with her husbands, Reo Fortune and Gregory Bateson, and later with students, Benedict remained at Columbia. There she edited the *Journal of American Folklore,* taught and published. Only after she separated from her husband and lived independently in New York did she have a regular post at the university.

Benedict's best-known work, *Patterns of Culture,* was the culmination of her interests in coherence of culture as a design for living. The work has long been recognized as an anthropological landmark. It developed from Boas's concern with ethnographic detail to the integration of a whole "culture". This notion that a culture, the total way of life of a people, could be characterized in a single word, Apollonian or Dionysian, was Benedict's unique insight; Modell feels it is her real achievement. Such a breathtaking whole view could not be achieved as a characterization of very many of the cultures studied by anthropologists, and this difficulty with the concept has been noted by a number of critics. However, the identification of themes and the relations between the individual and cultural values became one of the main lines of anthropological inquiry and had wide influence. At the beginning of the Second World War, Benedict and Mead, with a group of anthropologists and psychologists, carried out studies of the personality and culture of contemporary peoples, especially in European and Asian nations. The best-known of these studies, Benedict's *The Chrysanthemum and the Sword,* became a handbook used by American occupation forces in Japan after the Second World War.

Benedict died in 1948 at the age of 61, Mead and others completing the work on national character. Since the early 1950s, however, the attempt to identify a single cultural theme or pattern has been criticized as oversimplification. This, then, the outstanding contribution of Benedict to anthropology, was not followed up successfully by the next generation of scholars. Benedict's approach to anthropology as one of the humanities declined as cultural and psychological anthropology became more scientific in its methods and results.

The discipline of anthropology may indeed have progressed beyond the goal of identifying a unitary cultural theme. Nonetheless the person and concepts of Ruth Benedict, as presented here by Judith Modell, are of lasting interest and value to students of life and of culture. □

Paula Brown Glick is Professor of Anthropology at the State University of New York, Stony Brook.

States of mind and of science

Peter Wason

From Folk Psychology to Cognitive Science: The Case Against Belief.
By Stephen P. Stich.
MIT Press: 1984. Pp.266. $22.50, £21.40.

THE ordinary reader might expect to learn from this book something about the so-called cognitive revolution which has transformed the science of psychology over the past few decades. After all, the title suggests something of this kind. Like folk medicine, folk psychology carries an unscientific, even a disreputable, connotation; it conjures up an image of untutored individuals who lack access to the sources of enlightenment. On the other hand, cognitive science has an honorific connotation, without the parochial aura of psychology and suggesting a lot of brainy people from some of the new disciplines (artificial intelligence, for example) all toiling together happily on fundamental epistemological problems and talking a language nobody else can understand.

The ordinary reader would not be entirely right. Dr Stich is not concerned with psychological research, but with a philosophical argument about the status of the mind and its cognitive capacities. His main concern is to propose that the concept of belief (and allied mental concepts) has no proper function in a scientific explanation of mental life. We have all got things wrong if we want to be taken seriously as scientists. Neither folk psychology, nor cognitive science, is accurately defined, but the former is assumed to comprise "a loose network of largely tacit principles, platitudes, and paradigms" based on mentalistic terms. The author's argument is that such folksy notions, re-introduced into cognitive psychology after the bleak days of behaviourism, are detrimental to scientific progress and have no place in scientific accounts. This echoes in a strange way Otto Neurath's *International Encyclopedia of Unified Science* (1955), with its aim of purging scientific terms of surplus meaning. It is strange because positivism is hardly considered respectable in advanced philosophical circles and certainly not among the adherents of cognitive science. It is not simply in politics that left and right end up advocating the same thing.

Although the author draws back from giving whole-hearted assent to the claim of a couple of other philosophers that folk psychology is a "degenerating research program", he would like to rule out from cognitive science any "content sentence" which expresses an intentional or propositional attitude. Thus none of the following gain admittance:

S believes that Ouagadougou is the capital of Upper Volta
S hopes that Ouagadougou is the capital of Upper Volta
S fears that Ouagadougou is the capital of Upper Volta
S desires that Ouagadougou is the capital of Upper Volta,

for the folk psychological use of terms such as "believes", "hopes", "fears" and "desires" do not "play a role in the best and most sophisticated theories put forward by contemporary cognitive scientists". The precise nature of these admirable theories remains unspecified, but one might raise the question of how a clinician can make a diagnosis of paranoia without reflecting upon the beliefs of the patient. Further, one might also point out that there are philosophers who have made interesting analyses of emotions in ordinary folk terms.

What are the proposals which the author commends in the place of such crude

The Tables Turned: An Evening Scene

Up! up! my friend, and clear your looks,
Why all this toil and trouble?
Up! up! my friend, and quit your books,
Or surely you'll grow double.

The sun above the mountain's head,
A freshening lustre mellow,
Through all the long green fields has spread,
His first sweet evening yellow.

Books! 'tis a dull and endless strife,
Come, hear the woodland linnet,
How sweet his music; on my life
There's more of wisdom in it.

And hark! how blithe the throstle sings!
And he is no mean preacher;
Come forth into the light of things,
Let Nature be your teacher.

She has a world of ready wealth,
Our minds and hearts to bless —
Spontaneous wisdom breathed by health,
Truth breathed by chearfulness.

One impulse from a vernal wood
May teach you more of man;
Of moral evil and of good,
Than all the sages can.

Sweet is the lore which nature brings;
Our meddling intellect
Misshapes the beauteous forms of things;
— We murder to dissect.

Enough of science and of art;
Close up these barren leaves;
Come forth, and bring with you a heart
That watches and receives.

This poem, by William Wordsworth, is taken from *Poems of Science*, a new anthology published by Penguin. The book is edited by John Heath-Stubbs and Phillips Salman, and among the poets represented are Shakespeare, Milton, Shelley, Walt Whitman, Louis MacNeice and John Updike. Price is £4.95 in paperback.

notions? His favoured option, carefully argued against other candidates, is "The Syntactic Theory of Mind" (STM). It is introduced in these words:

> The basic idea of the STM is that the cognitive states whose interaction is (in part) responsible for behaviour can be systematically mapped to abstract syntactic objects in such a way that causal interactions among cognitive states, as well as causal links with stimuli and behavioural events, can be described in terms of the syntactic properties and relations of the abstract objects to which the cognitive states are mapped. More briefly, the idea is that causal relations among cognitive states mirror formal relations among syntactic objects. If this is right, then it will be natural to view cognitive state tokens as tokens of abstract syntactic objects.

I do not find this altogether intelligible, and not just because I fail to understand how objects can have a syntax. I do not really grasp how a theory such as this (however elaborated) could illuminate mental processes, and particularly the ways in which they go wrong in real life. However, it will be retorted (rightly) that the theory is not *really* a theory at all, but a kind of prolegomenon for a cognitive theorizing. One might suppose, then, that it is meant to be a methodological prerequisite for research, on the analogy with the methodologies for behaviourism which were proposed in the 1940s and 1950s. But there seems to me an interesting difference between them. The philosophers of science who analysed the concepts of behaviourism, as well as the concepts of the physical sciences, based their research on the use of the concepts within the theories. Philosophers of mind tend to ignore previous theory and appeal to their own insights, conjectures and intuitions, paraded forth in a series of pregnant sentences. There is nothing wrong with this, and it is often quite effective in advancing an argument. But the logical precision achieved in this way is also likely to be much more puzzling to the non-specialist than was the more discursive work of some of the great philosophers of the past.

There is a real danger that philosophers will end up talking only to each other and abandon their traditional role of protecting us from conceptual confusion. My doubt about the present book is whether its thesis will be of interest to experimentalists. It is a doubt rather than a verdict. Although Stich's arguments are nearly always compellingly precise, I am unsure whether they are consequential, or merely dazzling moves in an intellectual game. In the nature of things, they will not be readily settled because assertions about states of mind are not to be verified like assertions about nerve impulses. So while this book may be of interest to philosophers and to cognitive scientists, it remains uncertain whether it will help the rest of us in trying to find out more about mental processes. □

Peter Wason is Reader in Psycholinguistics at University College London. With P.N. Johnson-Laird he is co-author of Psychology of Reasoning: Structure and Content *(Batsford, 1972).*

Talk of research

Augustine Brannigan

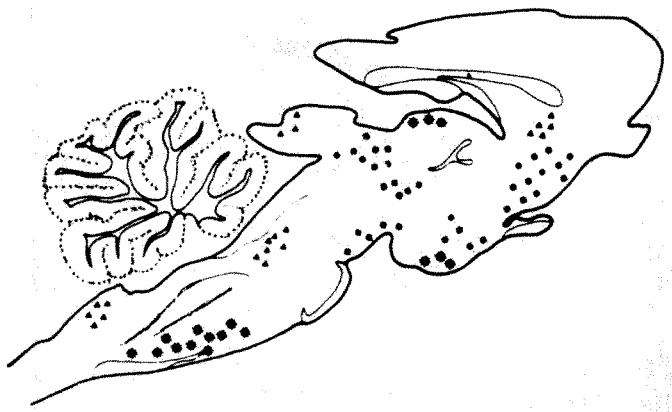
Opening Pandora's Box: A Sociological Analysis of Scientists' Discourse.
By G. Nigel Gilbert and Michael Mulkay.
Cambridge University Press: 1984. Pp.202. Hbk £22.50, $37.50; pbk £7.95, $12.95.

OVER the past decade, a close descriptive approach to scientific behaviour has revived interest in the cognitive and social dimensions of contemporary scientific knowledge. Following in this direction, the Pandora investigation focused on a recent controversy in biochemistry. The study is based on intensive interviews with 34 bioenergists in the United States and Britain, as well as on a sample of their correspondence and a reading of the literature in the field between 1960 and 1980. This period witnessed the rise of competing theories to explain how the crucial ATP molecule was able to move and temporarily store energy in living cells. In 1978 Peter Mitchell was awarded a Nobel Prize for chemistry for his work on the role of oxidative phosphorylation in ATP formation.

However, research by the authors indicated that members of the "ox-phos" community, as it is called, were far from in agreement about what exactly had been discovered in chemiosmotic research, about the empirical validity of the various bits of evidence, and about the respective parts played by the leading contributors. In their travel between the various biochemical laboratories, Gilbert and Mulkay report they were struck by the fact that although they realized that they were being given radically different accounts by participants of what "really" had happened, each account seemed, on its own, plausible and convincing.

Rather than trying to find out who was "really" correct and who was in error, the sociologists, not being in the business of second-guessing biochemical questions, turned their attention to what they describe as "discourse analysis". This is what opens Pandora's Box. Discourse analysis requires that the sociological observer remains neutral as to who is "actually" correct, the object being to determine *how* the respective participants produce and maintain their own sometimes contradictory versions of reality in the face of what would seem to be a set of invariant natural facts.

The Pandora investigation was not undertaken as a critique of science, for Gilbert and Mulkay go well beyond observations of how scientists selectively expose themselves to natural facts and selectively perceive and retain them. The heart of their inquiry is the observation that scientists employ two repertoires or codes of discourse for talking about how nature is discovered. The familiar empiricist frame of mind explains progress as following naturally from adherence to careful observation, and the testing of rival hypotheses in controlled experiments. In addition to this, scientists also employ what is called a "contingent" repertoire in which progress is traced to unique, subjective or situationally specific factors. Gilbert and Mulkay illustrate the use of these two conflicting repertoires in a fascinating contrast between the informal factors that influenced the investigation and interpretation of "ox-phos" experimental data reported to them in interviews, and the formal rationality provided in the earlier published articles of the same researchers. Rather than siding with the informal "inside" story as the true one, they instead stress that the accounts given of actions vary with the needs of the circumstance in which they are produced. Different accounts draw from the original experience in different ways depending on the formality or informality of the situation.



Having made a convincing case for the existence of two separate repertoires for reporting the progress of chemiosmo theory, the authors then go on to suggest that these repertoires are employed to explain the differential acceptance of scientific beliefs across the community. While one would expect that consensus ought to follow closely the reading of the facts, this is not the case. The evidence shows that scientists typically ground their own beliefs in empiricist discourse, as following from the experimental results, while explaining the position of opponents in the contingent repertoire: opponents wrongly interpret the facts because of subjective bias, experimental incompetence, theoretical ignorance — and even national origins! This switching between the two repertoires virtually guarantees that opponents will talk past one another. According to the authors, the device which saves the community from solipsism is the belief that in the end "the truth will out" — though how, when and in whose favour, no one can determine beforehand.

Other highlights of this work include an outstanding analysis of the tension between the virtual versus the fictional elements in scientific drawings of the chemiosmotic mechanisms. One informant dubs them "working conceptual hallucinations". There are also discussions of consensus and the significance of scientific humour. Each of these topics is explored usefully in the context of the two-repertoire dichotomy. While based on a single scientific speciality, the lessons of this investigation probably have wide currency in all areas of science, especially where controversy mobilizes the two incommensurable structures of discourse identified here. For that reason the book will be read with profit by practising scientists as well as by sociologists of scientific knowledge. □

Augustine Brannigan is Associate Professor of Sociology at the University of Calgary, Alberta.

Frontiers in Neuropsychiatric Research

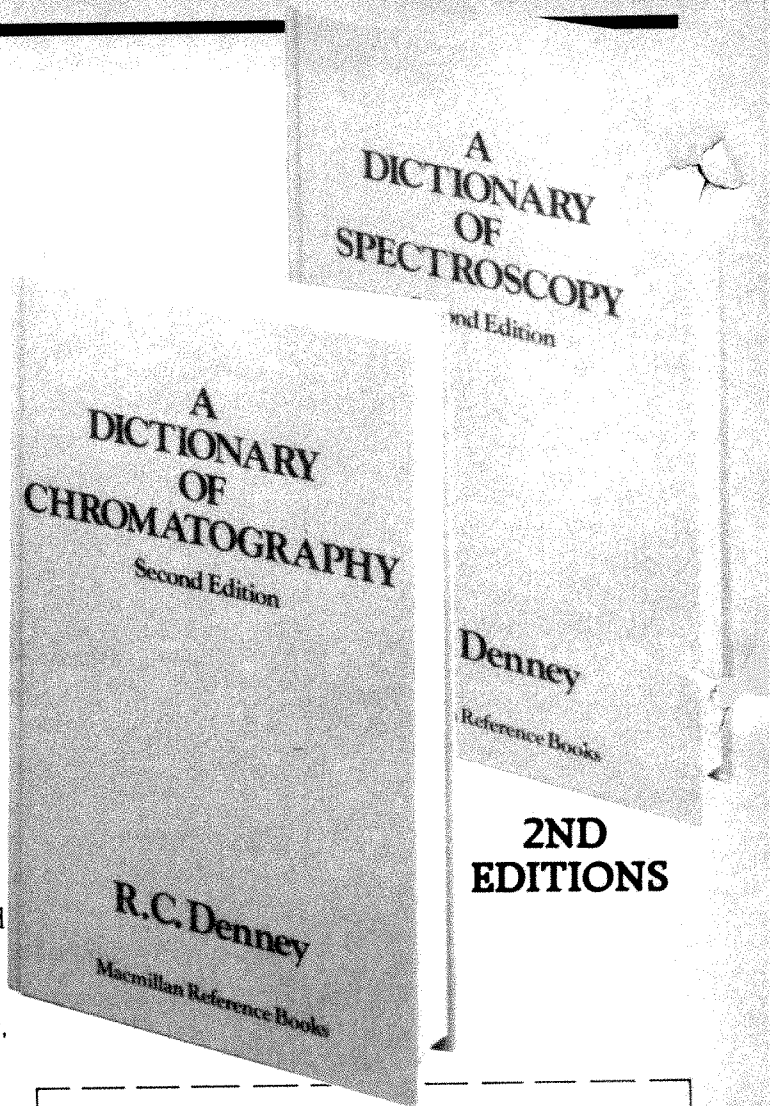
Department of Psychiatry, New York University School of Medicine, USA
Arnold J.Friedhoff,
Department of Psychiatry, New York University School of Medicine, USA

£40.00; 380pp; ISBN 0 333 347447

Based upon the proceedings of a CINP satellite symposium held in Corfu in June 1982, this book brings together contributions from the many fields involved in psychiatric research

Contents



Preface – Arnold J.Friedhoff; **Section I – Alterations of Neurotransmitter Systems in Affective Disorders –** Noradrenergic signal transfer as a target of antidepressant therapy – *Fridolin Sulser, Fumihiko Okada, D.Hal Manier, David D.Gillespie, Aaron Janowsky and Radhakanta Mishra;* Trans-synaptic mechanisms in the action of imipramine – *M.L.Barbaccia, De-Maw Chuang, O.Gandolfi and E.Costa;* Regional variations in 5-HT receptor populations and in ^{3}H-imipramine binding sites in their responses to chronic antidepressant treatment – *K.Fuxe, S-O.Ögren, L.F.Agnati, F.Benfenati, L.Cavicchioli, B.Fredholm, K.Andersson, C.Farabegoli and P.Eneroth;* The possible role of central epinephrine, α_2-adrenoreceptors and presynaptic dopamine receptors in affective disorders– *Menek Goldstein, Jorgen Engel, Isaac Regev and Shogo Mino;* Molecular aspects of regulation of α_2-adrenergic receptors – *D.C.U'Prichard, B.D.Perry, C.H.Wang, J.C.Mitrius and D.J.Kahn;* **Section II – Mechanisms of Action of Antidepressant Drugs –** Serotonin selective reuptake inhibitors - relationship between chemical structure and pharmacological effects *S.Agurell, H.Hall, T.Högberg, U.H.Lindberg, T.de Paulis, S.B.Ross and S-O.Ögren;* Effects of chronic administration of antidepressant drugs on central serotonergic receptor mechanisms – *S-O.Ögren, K.Fuxe, O.G.Berge and L.F.Agnati;* Neurochemical effects of the atypical antidepressant diclofensine in the rat – *W.P.Burkard, H.H.Keller, M.Da Prada and W.Haefely;* Oxaprotiline and its enantiomers: do they open new avenues in the research on the mode of action of antidepressants? – *A.Delini-Stula, A.Vassout, K.Hauser, H.Bittiger, U.Buech and H-R.Olpe;* Effects of single and multiple doses of antidepressant drugs on the ^{3}H-spiperone-labeled serotonin receptors in the frontal cortex of the rat – *Claes Rüdeberg;* Relationship between adaptive changes in brain α_2- and ß-adrenergic receptors following repeated imipramine, yohimbine and electroconvulsive shock treatment to rats – *A.I.Salama, A.Garcia, C.H.Wang, L.Lin and D.C.U'Prichard;* A review of the properties of a new specific 5-HT reuptake inhibitor - fluvoxamine maleate – *Jennifer S.Wakelin;* Biochemical and physiological mechanisms of action of carbamazepine in affective illness – *Robert M.Post and Thomas W.Uhde;* **Section III – Atypical Antidepressants and Mechanisms of Action –** Bupropion: an empirical pharmacological approach to drug development – *Loren Miller and Warren Stern;* Antidepressant and potential antimanic actions of GABA receptor agonists – *G.Bartholini, B.Scatton, B.Zivkovic, P.Worms and K.G.Lloyd;* Fluoxetine: a clinically effective non-tricyclic antidepressant – *Louis Lemberger, Ray Fuller, David Wong and Paul Stark;* The dexamethasone suppression test as a research variable – *John F.Greden;* **Section IV – Correlation of Biological and Clinical Factors in Affective Disorders –** Progress in pharmacotherapy of depression: research implications – *Anastasios Georgotas, Daniel Bush, William E.Hapworth, Mary Kim and Samuel Gershon;* Relationship of anxiety disorders to affective disorders – *David L.Dunner;* Application of sleep investigations in understanding antidepressant drug–clinical drug interactions – *David J.Kupfer and James Perel;* **Section V – Clinical and Basic Aspects of Affective Disorders –** Biochemical aspects in striatal dopamine receptor desensitization – *Ingeborg Hanbauer and Maurizio Memo;* Receptor–receptor interactions: possible new mechanisms for the action of some antidepressant drugs – *L.F.Agnati, K.Fuxe, F.Benfenati, L.Calza, N.Battistini and S-O.Ögren;* A double-blind comparative trial of oxaprotiline with amitriptyline and placebo in outpatients with moderate depression: relationship of urinary MHPG levels – *The Oxaprotiline Study Group;* Platelet α_2-adrenergic receptor activity in clinical studies of depression – *R.H.Lenox, J.E.Ellis, D.A.Van Riper, Y.H.Ehrlich, J.M.Peyser, J.E.Shipley and L.A.Weaver;* The olfactory bulbectomized rat as a model of depression – *Suzanne Jancsár and B.E.Leonard;* Closing Remarks – *Peter Hartocollis;* Index.

Essential for all Chemists

2ND EDITIONS

When you work or study in a field which is changing as fast as spectroscopy and chromatography it's not easy to keep up-to-date with all the new developments. New instruments are constantly appearing on the market and new techniques are being evolved in one of the fastest growth areas of modern science.

These dictionaries of chromatography and spectroscopy, already highly acclaimed in their previous edition, will enable you to:

* **broaden your knowledge of new products and instruments**
* **obtain rapid explanations of new terms and techniques**
* **relate your own speciality to other areas**
* **check symbols and equations quickly and efficiently**

A Dictionary of Spectroscopy covers such areas as atomic spectroscopy, emission spectroscopy, electron spin resonance, infrared and ultraviolet spectroscopy, nuclear magnetic resonance, photoelectron spectroscopy, photo luminescence, mass spectroscopy and Raman spectroscopy.

A Dictionary of Chromatography covers gas chromatography, gas liquid and gas solid chromatography, liquid chromatography, paper chromatography and thin layer chromatography.

Both dictionaries are clearly illustrated with over 50 drawings and diagrams and give numerous references for further specialised reading.

To order, just fill in this form and send it today.

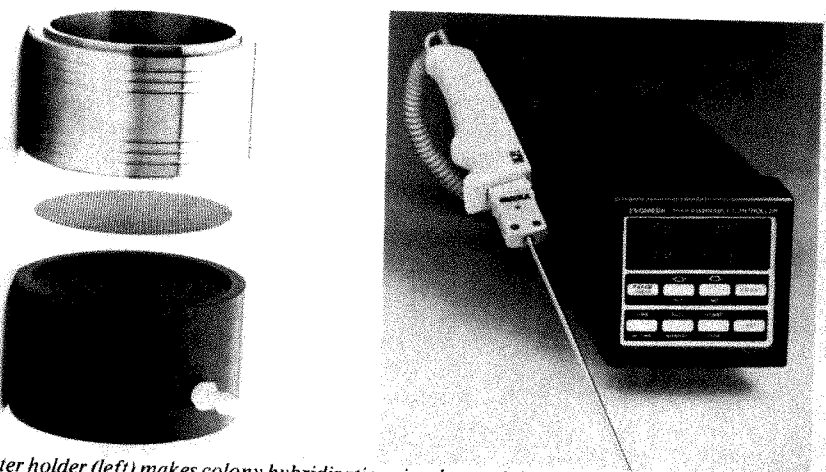
Circle No.93 on Reader Service Card.

Bags for waste, filters for hybridization

This month's new products include a filter holder for colony hybridization and autoclavable bags for the disposal of hazardous waste.



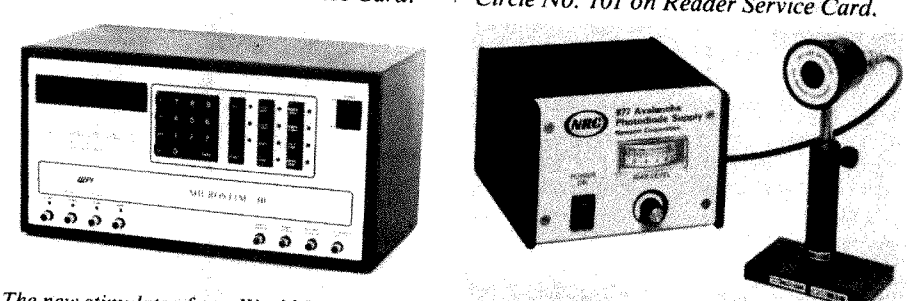
● The colony hybridization technique used in identifying bacteria in a large population which contains specific cloned nucleic acid fragments can be made simpler with the Schleicher & Schuell MV 08210 filter holder. Lysing, chloroform treatment, washing before and after hybridization, and hybridization itself can be carried out on the membrane-blotted replica colonies in the filter holder. Colonies are prevented from merging into each other when the holder is used. The apparatus is self-sealing and fitted with a 250 ml capacity stainless steel funnel, suitable for fitter diameters of 82/87 mm.
Circle No. 100 on Reader Service Card.

● The MS III is a sophisticated stimulator produced by World Precision Instruments Inc. It is microprocessor controlled and all stimulus parameters are entered using a numeric key pad. All keystroke entries are menu-prompted on a sixteen-character alpha/numeric display. Stimulus protocols may be assembled using any of eight pre-programmed or eight user-defined waveforms. MS III will store up to eight protocols in battery backed-up memory and may be interfaced with a computer via its RS232 port.
Circle No. 101 on Reader Service Card.

● The Sera-Lab range of monoclonal antibodies now includes the mouse mono-PAP, monoclonal mouse peroxidase anti-peroxidase antibody (catalogue no. RP-2000). Like the rat mono-PAP already available, this gives a sensitive method with very low nonspecific background staining for demonstrating immunoreactive sites.
Circle No. 102 on Reader Service Card.

● Vitatron Scientific B.V. of Dieren, the Netherlands have introduced a new series of photometers, called the IFP and the ISP. The IFP is fitted with a flexible cuvette system that can hold either four cuvettes or a Vitatron draincell, and which can be thermostatted through a waterbath. The ISP is equipped with a flow-cell for low volumes, suitable for routine analyses. Both photometers incorporate a complete range of procedures and calculations for both kinetic and endpoint measurements. Kinetic measurements can be carried out as either an integral of the curve with a check on linearity, or as two-point measurement. Results can be calculated using reagent blank or sample blank corrections.
Circle No. 103 on Reader Service Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Service Card bound inside the journal.



A new filter holder (left) makes colony hybridization simpler, and the Omega CN2010 does the same for temperature control.

● The Newport Model 875 high-speed PIN photodetector has broad spectral sensitivity from 400 to 1,060 nm and sub-nanosecond risetime. The detection area is large and is easy to align in a beam. An optional optical fibre input is available. The Model 877 ultra-high speed APD photodetector has rise and fall times of less than 200 picoseconds. It is useful for characterizing laser diodes as it is designed to detect and resolve ultra-short pulses of visible light. Both feature rechargeable battery power supplies.
Circle No. 104 on Reader Service Card.

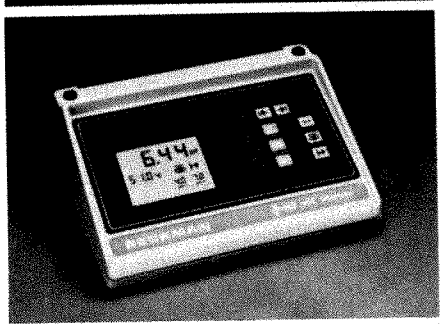
● Marubishi bench-top cell cultivation fermentors for animal and mammalian cells are now available in the United States from Bioengineering Associates Inc. These fermentors are suitable for a wide range of cell types and methods of cell cultivation, including cell suspension, microcarriers, hybridoma and plant cells. Agitation is produced gently by a marine-type propellor driven by magnetic coupling to eliminate any penetration of the fermentation chamber. Automatic temperature control within 0.5°C is achieved by a proportional controller balancing the output of an electric heating unit with the flow of a cool water circulating system.
Circle No. 105 on Reader Service Card.

● New from Pharmacia P-L Biochemicals, "Gene cartridges" are a group of promoters, antibiotic resistance genes and multi-site linkers used to custom-tailor cloning vectors to the customer's specifications. The range includes cloning vectors, oligonucleotides, molecular biology enzymes and restriction nucleases, all listed in the Pharmacia PL "Product Reference Guide".
Circle No. 106 on Reader Service Card.

● The new Omega CN-2010 programmable temperature controller features a "ramp and soak" function, which controls the temperature and its rate of change over a predetermined time span when more than one temperature is required to complete a process. Up to eight ramp and soak intervals can be programmed, each with a time duration of up to 254 repeat cycles. The CN-2010 has a multisetpoint function that allows presetting of up to nine independent setpoints. The controller accepts any standard thermocouple, RTD sensor, d.c. voltages up to 200 V or d.c. currents up to 200 mA. It will also interface with a host computer via an RS-232C, RS-422 or 20 mA current loop, allowing the user to access all input parameters and output values and assume direct control of outputs.
Circle No. 101 on Reader Service Card.

The new stimulator from World Precision Instruments (left) and Newports' photodetector.

● Polypropylene disposable bags for autoclaving and sterilizing contaminated products are available from Sarstedt Inc. The bags are printed with prominent biohazard labels and come in three sizes. They can be autoclaved at up to 148°C.
Circle No. 108 on Reader Service Card.



● Tekspensor adjustable volume dispensers from Tekmar use micrometer adjustment for precise repeatability to dispense volumes from 0.4 to 100 ml with no mechanical slippage. Accuracy and reproducibility are better than ± 0.1%. The dispensers are made of chemically inert materials and the calibrated piston, suction tube and ejection tube are PTFE coated to minimize freezing problems associated with all-glass dispensers.
Circle No. 109 on Reader Service Card.

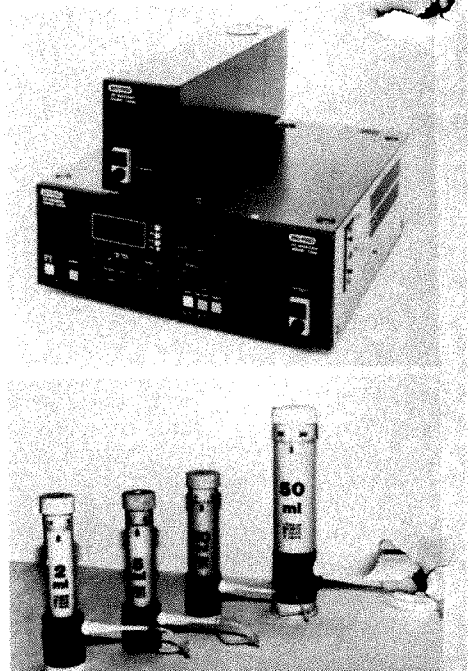
● The Bio-Rad Model 1305A variable wavelength UV monitor is a detector designed for chromatographic applications which require high sensitivity with low noise and drift. The monitor provides digital readout of absorbance, transmittance, or photo detector output independent of the recorder. The standard deuterium lamps allow a 190 to 350 nm wavelength range. The monitor may be upgraded by adding the optional tungsten lamp which extends the range from 350 to 600 nm. Sensitivity is selectable in eleven steps from 0.005 to 5.12 ABS/full scale. A time constant switch permits selection of a fast or slow response time. The monitor features separate electronic and optical modules to conserve bench space, and convenient interchangeable cassette-type flow cells for analytical, preparative, microbore, ultra-microbore and classical open column chromatography. The Model 1306 UV monitor is a simpler device for applications which require detection in the 190 to 350 nm wavelength only. The optical and the electronic components are located in the same unit, which makes this detector more compact than the Model 1305A.
Circle No. 110 on Reader Service Card.

● Chromatographic data can be acquired, analysed and reported using the new Adalab chromatograpy data system, Chromatochart and an Apple II computer. Data can be acquired from capillary and packed column gaschromatographs, HPLCs, gel scanners, TLC densitometers and amino acid analysers. It integrates and provides LC gradient control on four channels simultaneously, storing methods, raw data and reports on floppy disk.
Circle No. 111 on Reader Service Card.

● The new shaking waterbath from Haake Buchler Instruments Inc. is designed for gently agitating laboratory samples while holding them at a controlled temperature, as well as for specialized uses such as thawing frozen plasma or whole blood. The entire volume of the stainless steel bath is usable, since the heater and sensor are mounted below the bath. A large area heater reduces hot spots and provides even heating throughout the bath.
Circle No. 112 on Reader Service Card.

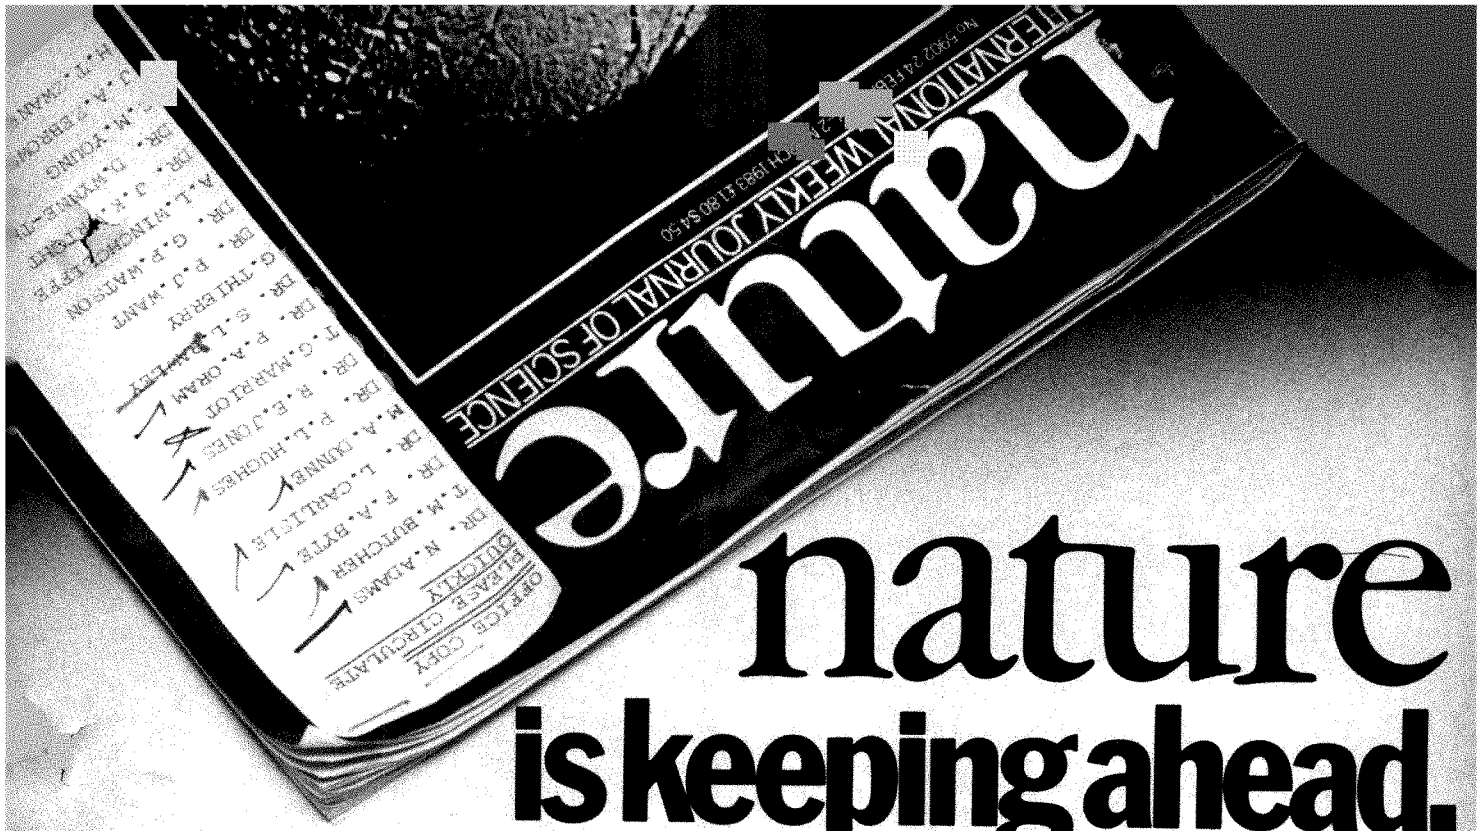
The Sarstedt disposable bag for waste (top) and Beckman's new pH meter.

● New from the National Appliance Company is a thermostatically-controlled waterbath capable of maintaining temperatures of 100°C when operated with or without a cover. Thermostatic controls allow use at lower temperatures, as well. A limiting thermostat protects the heater element from low-water conditions.
Circle No. 113 on Reader Service Card.



● Falcon Labware has introduced new 17 × 100mm round-bottom tubes for use in the collection processing, storage and centrifugation of biological specimens. The tubes have graduations for easy volumetric reference and are available fabricated from either polypropylene or polystyrene. The tubes are delivered sterile with a patented dual-position cap. The first position closes the tube but permits aerobic culturing of microbiological specimens. The second position fully seals the tube allowing it to be used for specimen storage and centrifugation.
Circle No. 114 on Reader Service Card.

● Standardized nucleic acid and immunological reagents for oncogene research are now obtainable from the North-London based company, Stratech Scientific Ltd. These highly purified, sequence specific DNA fragments have been designed for use in nick translation reactions and for the detection of oncogenic sequences by nucleic acid hybridization. Also available are antibodies for the detection of oncogene protein products and related antigens.
Circle No. 115 on Reader Service Card.



● Intended for routine and complex HPLC application, Gilson's new variable wavelength UV detector permits easy user programming of all instrument parameters. Operating from 190 to 380 nm, the Model 116 features a sensitivity range of 0.001-2.0 AUFS adjustable in increments of 0.0001 AUFS. The user can monitor at two different sensitivities simultaneously. Other features include a build-in keypad and computer interface.
Circle No. 116 on Reader Service Card.

● Human leukocyte interferon (α-IFN) intended specifically for AIDS research can now be obtained from Schwarz-Mann. It is prepared from normal human buffy coat cells induced by Sendai virus, purified by a modified Cantell method. The preparation is free of Sendai virus when assayed by haemagglutinin after serial passage through chicken eggs, and is free of hepatitis B surface antigen. Anti-human interferon α, purified human leukocyte interferon (α-IFN) and anti-human interferon β are also available.
Circle No. 117 on Reader Service Card.

● The Beckman PhI 40 bench-top *p*H meter is a simple-to-use instrument for accurate *p*H measurement in quality control, environmental and research laboratories. A custom-designed integrated chip gives the meter the sophistication of more costly models while making it easy to use. Most measurement steps are automated for nearly unattended measurement and simple operation. It has error and out-of-temperature-range warnings; always displays temperature; and does temperature computations with or without an automatic temperature compensation (ACT) probe. It features a digital-to-analog converter for simplified recorder setup.
Circle No. 118 on Reader Service Card.

The Bio-Rad 1305A (top) and Tekspensors from Tekmar.

nature is keeping ahead. Are you being left behind?

New research results, the very latest international science news, key papers by the world's leading scientists and speed of publication ensure *Nature* remains one of the foremost weekly scientific journals in the world.

But if you're tied in to a circulation list at work, all this vital weekly information will undoubtedly reach you late, often incomplete and sometimes not at all.

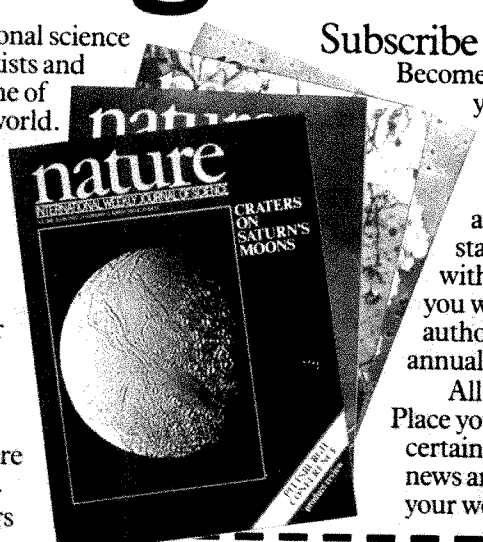
With your own personal copy, you solve the problem. Every week you'll have all the latest research results and science news in your hands within days of publication:

News reports from throughout the world of science and technology.

A **News and Views** section, where new ideas are analysed and discussed by leading researchers.

Articles and Letters in which key investigators disclose their work for the first time.

Book Reviews—Eminent figures offer expert judgments on a wide variety of recent publications.



Special Issues providing an in-depth treatment of topics of importance.

Product Reviews—Detailed descriptions of laboratory equipment newly available.

Classified Advertisements for a wide variety of positions all over the world.

You will no longer be dependent upon other people passing down the 'list' copy, and because you will automatically receive every issue, you won't risk missing a single copy through absence from work. Moreover, you keep all this key information for permanent reference.

Through your door every week

Subscribe now–and save!

Become a personal subscriber now and you will receive a discount of over 50% off the full rate.

All 51 weekly issues will be delivered to the address of your choice. You can start your annual subscription with any issue you choose. And you will receive six bi-monthly author indexes, together with the annual index of subject and author.

All this for just $2.12 a week.

Place your order now and make certain that you receive the scientific news and research results crucial to your work when *you* want them.

☐ I accept: Please send me a personal subscription to *Nature* for one year (51 issues) at the special rate of US$110.

☐ I enclose my personal check for US$110 made payable to Nature. (Note: Institutional checks cannot be accepted at this special rate. The institutional price is US$230.)

☐ Please charge to my credit card account.

UNIVERSITY OF ABERDEEN

DEPARTMENT OF FORESTRY

RESEARCH ASSISTANT (Ref 2)

Required for a 15-month NERC-funded project on tissues and protoplast culture of alder and birch as part of a wider study of the application of biotechnology to the improvement of forest trees. Candidates should have a good honours degree in Botany, Biochemistry or allied discipline with experience of in vitro culture methods.

Salary on the Range 1B scale for Research and Analogous Staff (£6,310 — £8,530) with appropriate placing (scale under review). The appointment is tenable until December 1985.

Further particulars and application forms from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 27 July 1984. Please quote Ref No 2 on application. (3067)A

THE UNIVERSITY OF MANCHESTER

DEPARTMENT OF ASTRONOMY

MANAGER OF THE STARLINK NODE

Applications invited for the above post to manage the Manchester Node of the Starlink network. Duties will involve the smooth running of the node, to assist users with problems and to contribute in the development of software for the Starlink project.

Applicants should have a degree in a numerate subject, at least three years of relevant computing experience. An interest or background in Astronomy would be an advantage. Post tenable initially for two years from October 1st, 1984 or as soon as possible thereafter.

Salary range pa: £7,190 — £11,615 (Superannuation). Particulars and application forms (returnable by July 20th) from the Registrar, The University, Manchester M13 9PL. Quote ref 151/84/N. (3058)A

HARVARD UNIVERSITY PEABODY MUSEUM

DEPARTMENT OF ANTHROPOLOGY

seek applicants for a newly-endowed Landon T Clay

PROFESSORSHIP OF SCIENTIFIC ARCHAEOLOGY

Applicants should have well established archaeological interests and be scientists with active research programs. In addition to pursuing his/her own research, the appointee will be encouraged to develop and direct a laboratory engaging in varied applications of the natural sciences to archaeological problems.

Women and minority group candidates are especially encouraged to apply.

Send detailed vita to Chairman, Department of Anthropology, Harvard University, Cambridge, MA 02138, by November 30, 1984. (NW644)A

UNIVERSITY OF LEICESTER SCHOOL OF MEDICINE

TEMPORARY LECTURESHIP IN ANATOMY

Applications are invited for a Temporary Lectureship in the Department of Anatomy tenable for one year from 1 November 1984. The successful candidate will be required to have a knowledge of topographical anatomy. The post is suitable for a scientist wishing to embark upon a career in anatomy or for a medical qualified graduate intending to the Primary FRCS.

Initial salary will depend upon qualifications and experience on the scale £7,190 to £14,125 (under review).

Further particulars from the Registrar, University of Leicester, University Road, Leicester LE1 7RH, to whom applications should be sent on the form provided by 31 July 1984. (3037)A

Senior Research Scientist

£22K·Bonus·Car

Smith Kline and French is a leading international pharmaceutical Company with a substantial commitment to research and development in the UK. Our laboratories at Welwyn, Herts are well equipped and amongst the most advanced in our field.

As part of our thrust towards the discovery of new medicines we are looking for a man or woman to join our team and contribute to the further development and direction of our cardiovascular research programmes.

The person we need should have experience in aspects of intracellular control of cardiac and/or vascular function and who can combine a range of scientific understanding to the solution of problems in this challenging area of research.

Applicants should possess a suitable qualification in life sciences combined with substantial research experience obtained in either academia or industry. There is plenty of scope for personal development.

Please ring 07073 25111 extension 3540 for further information or an application form or send a detailed cv (ref no N/973/TF) to Dr T E Forster.

SK&F

SMITH KLINE &FRENCH RESEARCH LIMITED
The Frythe, Welwyn, Herts AL6 9AR.

(3095)A

MACQUARIE UNIVERSITY SYDNEY AUSTRALIA

LECTURER IN BIOLOGY

LECTURER IN PHYSICS

Equality of Employment Opportunity is University Policy.

Applications are invited for appointment to the following lectureships tenable not before 1 February 1985 for a fixed term of five years.

Salary (under review) $A24,353 to $A31,994 p.a.

Further information about the University and advice regarding the method of application should be obtained from the Secretary-General, Assocation of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF, England, or from the Registrar, Macquarie University, North Ryde, New South Wales 2113, Australia.

Applications close 3 August 1984.

LECTURER IN BIOLOGY in the FIELD OF MOLECULAR BIOLOGY,

SCHOOL OF BIOLOGICAL SCIENCES

Preference will be given to applicants with experience in recombinant DNA techniques, for example vector construction involving either E coli or S cerevisiae plasmids, and DNA sequencing. Good prospects exist for collaborative research at the molecular level with existing research groups within the school currently working in plant physiology/biochemistry, virology (particularly of the Herpes group), developmental biology of Dictyostelium and X-inactivation of marsupials. The CSIRO Plant Physiology Unit of the Division of Food Research is also located in the School and regularly participates in collaborative projects.

The successful candidate will be expected to assist in the teaching of undergraduate courses (mainly at the upper level) and to supervise postgraduate research students. Further information about the position can be obtained from Professor D W Cooper, Head of the School of Biological Sciences.

LECTURER IN PHYSICS, SCHOOL OF MATHEMATICS AND PHYSICS (which also includes ELECTRONICS and COMPUTING)

The duties of the appointee will include teaching in physics to honours degree level (some teaching in electronics may also be required) and conduct of research in Physics including postgraduate research supervision. The field of research interest of applicants is not restricted, but some preference may be shown for physicists with strong theoretical backgrounds who are interested in interaction with experimentalists working in the areas of optical physics, atomic and molecular physics, physics of materials (including thin films) and other areas of interest in the discipline.

June 1984. A J T Ford, Registrar. (W1088)A

THE UNIVERSITY OF AUCKLAND NEW ZEALAND

DEPARTMENT OF PSYCHIATRY AND BEHAVIOURAL SCIENCE

AN ASSOCIATE-PROFESSORSHIP IN BEHAVIOURAL SCIENCE

Closing date: 1 October 1984. This position, which has been created to head the Behavioural Science Section within the newly combined Department, involves the organisation and administration of the five year Behavioural Science teaching programme within the present medical course. Candidates should hold a doctoral level qualification in a Behavioural Science discipline such as Psychology or Sociology. Preference will be given to those with experience of teaching Behavioural Science in a medical context, and experience of teaching Behavioural Science in clinical settings would be an advantage. The successful applicant will be expected to undertake substantive research work in Behavioural Science or Behavioural Medicine and organisational or leadership experience would be desirable.

DEPARTMENT OF PHARMACOLOGY AND CLINICAL PHARMACOLOGY

A LECTURESHIP/SENIOR LECTURESHIP (NON-MEDICAL) IN PHARMACOLOGY

Closing date: 31st August 1984. Candidates must hold a PhD degree in pharmacology, physiology, biochemistry or a related discipline. Preference will be given to candidates with experience in teaching in practical classes in Science pharmacology. Candidates with experience in teaching in practical classes in Science pharmacology. Candidates should have proven ability to teach and conduct independent research. Preference may be given to those with a research interest in one of the following areas: pharmacokinetics, drug metabolism, applied cardiac or autonomic pharmacology or neuropharmacology, adenosine pharmacology or metabolism.

Commencing salaries will be established within the appropriate scale. Present scales are: Associate Professor is NZ$37,896 per annum; Senior Lecturers NZ$27,088-$30,127 per annum; and Lecturers NZ$21,660-S$25,684 per annum. Salaries are currently supplemented by an $8 week cost-of-living allowance. Conditions of Appointment and Method of Application are available from the Assistant Registrar (Academic Appointments), University of Auckland, Private Bag, Auckland, New Zealand, or from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications in accordance with the Method of Application should be forwarded as soon as possible but not later than the closing dates stated. (W1085)A

BIOTECHNOLOGY

Celltech is one of the World's leading specialist biotechnology companies. Based in the UK. The Company is backed by four major City of London financial institutions. A strong scientific team has now been built up in the areas of recombinant-DNA and cell-hybridisation and continued expansion is envisaged; close links are also maintained with the academic community. The Company aims to exploit the potential of discoveries arising in the field of biotechnology, and commercial successes have already been achieved in several areas.

MOLECULAR BIOLOGISTS

We require post-doctoral molecular biologists (or graduates expecting to obtain a PhD this year) to join our molecular biology and immunology divisions. The successful candidates will be involved in the cloning and sequencing of genes coding for commercially important proteins. Expertise in isolation and handling nucleic acids is desirable. Previous experience in the preparation and cloning of cDNA will be an advantage.

Please quote reference number 205.

MOLECULAR GENETICS

A position is available in the Molecular Genetics Department for a post-doctoral Scientist to join a group developing novel mammalian gene expression systems. Experience with viral vectors or amplifiable genes is desirable.

Please quote reference number 206.

GROUP LEADER

We are currently seeking an experienced person to lead our protein microsequencing facility. The post will involve research into sequencing methods, interactions with recombinant-DNA project teams and an involvement in downstream processing and quality control.

Please quote reference number 207.

TECHNICIAN IN HYBRIDOMA Immunology

We are currently seeking a technician to make monoclonal antibodies within our Hybridoma group.

Experience in tissue culture is essential and knowledge of serological assays and fusion techniques would be advantageous.

This position would suit an HNC/HND or first degree applicant.

Please quote reference number 208.

To apply, please send a full C.V. to Jane Walley, Personnel Officer, Celltech Limited, 244 Bath Road, Slough, Berks. SL1 4DY quoting the appropriate reference number.

CELLTECH

IRI

Inveresk Research International

MASS SPECTROMETRY

Inveresk Research International Limited, an expanding contract research organisation, now has the following vacancy within its area of Analytical Chemistry:—

RESEARCH OFFICER/ MASS SPECTROMETRY

This vacancy is for a chemist conversant with the use of mass spectrometry in the analysis of biological samples. Applications include the development of GC and HPLC separation techniques and the identification and measurement of drugs and metabolites in body fluids.

The successful candidate will assume responsibility for a Finnigan 4500 mass spectrometer and data system, and will liaise with research groups in metabolism and chemistry.

Applicants should have a PhD in applied mass spectrometry in the biological sciences or should be graduates with similar experience.

Salary will be on the scale £7,599 to £9,033 or £8,811 to £10,485, with placement depending upon qualifications and relevant experience. In addition, the Company offers modern staff benefit schemes, including free private health care, and pleasant working conditions in a rural setting close to Edinburgh. Relocation assistance may also be provided, where appropriate.

Full details in writing should be forwarded to the Personnel Department, Inveresk Research International Limited, Inveresk Gate, Musselburgh, quoting reference 1440.

(W1087)A

PUBLIC HEALTH LABORATORY SERVICE BOARD

PHLS Centre for Applied Microbiology & Research

Microbial Technology Laboratory

MOLECULAR GENETICIST

A Molecular Geneticist is required to join a group in the Microbial Technology Laboratory concerned with all aspects of cloning and gene expression. Systems under investigation include the cloning of bacterial genes of potential commercial interest, the sequencing of viral genomes and the cloning of eukaryotic genes.

Candidates should have an appropriate honours degree and post graduate experience in Molecular Genetics with preferably some experience in the cloning and expression of eukaryotic genes.

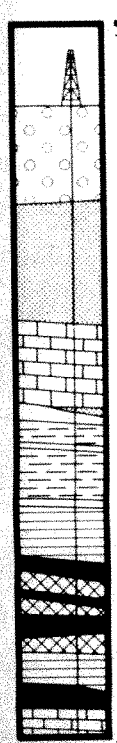
Salary will be either in the Basic Grade £6,277 — £8,349 or Senior Grade £9,010 — £11,649 Microbiologist scale as appropriate. National Health Service terms and conditions will apply.

Further details on the nature of this post can be obtained by contacting Dr N Minton, Microbial Technology Laboratory, CAMR, Telephone 0980 610391.

Application forms can be obtained from Mrs M Bushby, Personnel Officer, CAMR, Porton Down, Salisbury SP4 0JG and should be returned together with a curriculum vitae and the name of two referees. Closing date will be 13th July 1984.

(2994)A

NORTH CALIFORNIA OCCUPATIONAL HEALTH CENTER



SENIOR RESEARCH TOXICOLOGIST

The Northern California Occupational Health Center is seeking a Senior Research Toxicologist with expertise in research methodology, and basic and applied toxicology. The individual may hold an MD or a PhD degree and have demonstrated ability to obtain basic research grants in her/his specialized area of occupational toxicology research. The individual should be anxious to work in collaboration with physicians working in a major occupational health program at UCSF School of Medicine with special expertise preferably in heavy metals or nephro-toxicology, or in occupational cancer, or neurotoxicology.

The University of California is an affirmative action employer which does not discriminate on the basis of race, sex, or age.

For inquiries please call or write: Charles E Becker, M D, Professor of Medicine, UCSF, Head, Divsio[illegible] Occupational Medicine and T[illegible]cology, San Francisco General Medical Center, 1001 Potrero Avenue, Bldg 30, 5th Floor, San Francisco, CA 94110; (415) 821-5200.

Applications must be received by August 10, 1984. (NW642)A

Micropalaeontologist

Based Aberdeen

We currently have an interesting opportunity within our Stratigraphic Laboratory in Aberdeen for an applied micropalaeontologist (specialising in Foraminifers).

The post will ideally suit candidates, with up to 3 years' post doctoral industrial/ academic experience, who are looking for a challenging appointment with close multi-disciplinary interaction.

The successful candidate will join a team of BP biostratigraphers who currently operate in Canton (China), Aberdeen and in the BP Research Centre, Sunbury-on-Thames, Middlesex.

An attractive remuneration package includes a non-contributory pension scheme, subsidised restaurant, on-site sports and social facilities and relocation assistance where appropriate.

Please write in detail, quoting reference SR 2618 to: Anne Hendry, The British Petroleum Company plc, BP Research Centre, Chertsey Road, Sunbury-on-Thames, Middlesex.

BP **BP Exploration Limited**

UNITED MEDICAL AND DENTAL SCHOOLS OF GUY'S AND ST THOMAS'S HOSPITALS

UNIT FOR METABOLIC MEDICINE, DEPARTMENT OF MEDICINE, GUY'S HOSPITAL MEDICAL SCHOOL

MEDICAL LABORATORY SCIENTIFIC OFFICER

Applications are invited from recent graduates in Biochemistry or Biological Sciences for a two-year funded post within the Unit for Metabolic Medicine (Director, Professor H Keen). The appointee will join a small group working on the macrovascular complications of Diabetes Mellitus and will play an important role in a current study investigating the efficacy of hypolipidaemic drug therapy in dyslipidaemia. The work involves lipid and lipoproteia separation and analysis using ultracentrifugation, enzymatic autoanalysis and immunological methods and includes technical assistance at patient clinics.

Salary during the first year of appointment according to age on scale £4,674—£4,818 per annum, rising after one year's satisfactory service to £5,491 per annum, plus £1,042 per annum London Weighting (salary scales under revision).

Applications, including age, qualifications, experience and the names of two referees, should be addressed to The Secretary, Guy's Hospital Medical School, London Bridge, London SE1 9RT, to arrive by 12th July, 1984, and quoting Ref. UMM1. (3010)A

MONASH UNIVERSITY
Melbourne, Australia

CENTRE FOR EARLY HUMAN DEVELOPMENT

DIRECTOR
FACULTY OF MEDICINE

The University Council wishes to appoint a Director to the Centre for Early Human Development following the appointment of the present Director, Dr J E Maloney, to a position at the University of Calgary. The position will be vacant as from 1 July 1984.

The Centre is situated at the Queen Victoria Medical Centre together with the University Departments of Obstetrics and Gynaecology, and Paediatrics. A new hospital with 436 beds is under construction at Clayton adjacent to Monash University and it is expected that it will be occupied by the Queen Victoria Medical Centre, the associated University Departments, and the Centre for Early Human Development OSC is approximately 478 square metres, excluding space shared with the University Departments.

The Centre for Early Human Development was established in 1978 to undertake research on prenatal and postnatal development and at present comprises an established multidisciplinary team working on aspects of cardiorespiratory physiology in the period surrounding birth. The new Director would be required to assure the continuance of this work and to seek to develop other aspects of research in early human development. Opportunities exist for collaboration with Departments of the University, both at Queen Victoria Medical Centre and at the adjacent main campus of the University, and with Departments of the Medical Centre. A medically qualified Director will have the opportunity of undertaking clinical responsibility in his field of expertise.

The appointment is for five years in the first instance. Enquiries about the Centre and the Faculty of Medicine may be directed to Professor G C Schofield, Dean of the Faculty of Medicine, Monash University.

Salary $A38,085 — $A51,006 per annum, depending on qualifications and experience. A loading will be paid to a medically qualified appointee. Provision for superannuation, outside studies programmes, travel and removal allowance, and temporary housing assistance.

Information on application procedure and further particulars may be obtained from the Registrar, Monash University, Clayton, Victoria 3168, Australia, or the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications should reach the Registrar not later than 15 August 1984. Council reserves the right to make no appointment or to appoint by invitation at any stage.

An equal opportunity employer.
(W1090)A

UNIVERSITY OF EDINBURGH

FACULTY OF VETERINARY MEDICINE

DEPARTMENT OF VETERINARY PATHOLOGY

Applications are invited from veterinary graduates for the post of lecturer in Pathology.

The Department has an integrated approach to research and teaching in all aspects of Pathology (immunology, microbiology, morphological pathology) and has considerable expertise and facilities for work in these areas. The person appointed will be expected to contribute to teaching in pathology, to share the service commitments in diagnostic pathology (including post mortem work) and to undertake further research training in pathology leading to a higher degree (PhD or MRC Path if this has not already been obtained).

The salary scale is £7,190 — £14,125 but initial appointment will not exceed £8,975 with first increment on October 1st 1984.

Six copies of application with the names of 3 referees should be submitted to the Secretary to the University, Old College, South Bridge, Edinburgh from whom further particulars can be obtained. Closing date for applications 13th July, 1984. Please quote Reference No.1140.
(2909)A

PRINCESS MARGARET CHILDREN'S MEDICAL RESEARCH FOUNDATION

Perth, Western Australia

CLINICAL IMMUNOLOGIST

(Joint Clinical and Research Appointment)

The Princess Margaret Children's Medical Research Foundation (CMRF) seeks suitably qualified applicants for a joint appointment to the Foundation's Clinical Immunology Research Unit (CIRU) and the Princess Margaret Hospital's (PMH) Clinical Staff.

Applicants are sought with F.R.A.C.P. or equivalent qualification, preferably in Paediatrics, and research experience in Clinical Immunology.

The salary level and status of the appointee will be commensurate with their joint responsibilities (1) to the Director of the CIRU as Research Fellow/Senior Research Fellow for research responsibilities within the Unit (conditions as per NH & MRC, plus clinical loading) and (2) to the Medical Director as Clinical Staff Specialist for Clinical and Laboratory service responsibilities (salary in accordance with the West Australian Metropolitan Teaching Hospitals Agreement 1978 — Clinical Staffs). For further information contact Professor K J Turner (Director, CIRU) by telephoning (09) 382 8592 or Dr D R Fry (Medical Director, PMH) on (09) 382 8241.

The appointment will be for an initial period of three years, after which the basis for renewal or permanence will be determined. Applications, including curriculum vitae and the names and addresses of three referees should be submitted to **Mr K Williamson, Secretary, CMRF, GPO Box D184, Perth, W.A. 6001, by August 31st, 1984.**

Experimental Biologist

Helminth Chemotherapy

Starting salary in the range £8,700 — £10,700
Beckenham

The Wellcome Foundation Limited is a major group of pharmaceutical and chemical companies with headquarters in the UK and a turnover close to £700m.

Our Department of Biochemical Parasitology at Beckenham now requires an experienced research Biologist to join its strong multidisciplinary team of biochemists, physiologists, chemists and parasitologists engaged in the research and development of new medical and veterinary anthelmintics. You will be expected to design and operate assays for the evaluation of anthelmintics and to undertake independent research within the framework of our research programme.

A first degree in Biological Science and a PhD in parasitology are essential, possibly with 1-2 years' post doctoral research experience. You will have a keen interest in the field of chemotherapy, and will enjoy both interacting in a team and independent work.

Appointment will be for a period of 12 months in the first instance with chance of renewal.

Excellent benefits include 5 weeks' holiday, pension and life assurance scheme, subsidised canteen and first class sports and social facilities.

Please write with full cv, quoting ref WRL/ 284, to Dr H D Avshu, Personnel Officer, The Wellcome Research Laboratories, Langley Court, Beckenham, Kent BR3 3BS.

Wellcome

Public Service Commission of Canada / Commission de la Fonction publique du Canada

Scientific Advisors, Toxicology

Health and Welfare Canada
Health Protection Branch
Ottawa, Ontario

We require experienced senior toxicologists to fill several positions in the Toxicological Evaluation Division. We will expect you to validate, review and evaluate reports on a range of toxicity studies on chemicals in the food supply, such as pesticides, food additives and chemical contaminants. You will become involved in the assessment of potential hazards and risks to public health. Employment in the division offers unique opportunities to gain diversified toxicological advisory experience in a government setting and to have input in the extensive research program.

You require a university degree with specialization in a biological science such as toxicology, pharmacology, biochemistry, with experience in laboratory animal toxicity studies and bioassays. In addition, you need experience in reviewing and evaluating reports on toxicity studies and in conducting health hazard and risk assessments. Some positions also require additional experience in preparing recommendations based on toxicological evaluations and health hazard assessments. Language requirements vary according to the position being filled.

We offer a salary ranging from $31,791 to $48,935 commensurate with your qualifications and experience.

Forward your résumé and/or application form, quoting reference number S-84-31-0293-47JG-(G26), to:
J. Girling (613) 993-5331

DIRECTOR

Goodwin Institute for Cancer Research

Applications are invited for the position of director. This chief executive scientist, reporting to a Board of Trustees, is responsible for the development of research programs, supervision of operations, and governmental and industrial relations associated with grants, contracts, and fund raising. The director is encouraged to conduct personal research.

The Institute, chartered in 1959 as a private, non-profit medical research corporation, moved into 30,000 square feet of new, well-equipped laboratories in 1980. The building also houses a Primary Genetic Center for specific pathogen-free rodents operated under contract with the National Cancer Institute. Current staff numbers 40 persons and annual budget is $2 million.

Candidates should have a Ph.D., D.V.M., or M.D. and be qualified to apply current biotechnology to studies of the molecular nature of experimental cancer induction, growth, and control. Administrative experience is essential, publications and acquired support are desirable, and imagination is useful.

Appy to: Search Committee, Goodwin Institute for Cancer Research, 1850 Northwest 69 Avenue, Plantation, FLa. 33313.

(NW629)A

WASHINGTON UNIVERSITY
DEPARTMENT OF CHEMISTRY
CHAIRMANSHIP

Applications are invited for the position of Chairman of the Department of Chemistry at Washington University, St Louis, MO. Applicants should have a strong research program, and proven teaching and administrative experience.

Interested scientists should submit a complete curriculum vitae and a list of at least three individuals who can be contacted for references to: Chairman, Chemistry Search Committee, Box 8094, Washington University School of Medicine, 660 South Euclid Avenue, St Louis, MO 63110.

Washington University is an Equal Opportunity Employer M/F/N/V

(NW626)A

IMPERIAL COLLEGE
NORTH SEA OIL RESEARCH

Applications are invited for an expanding programme of research into reservoir and recovery problems related to North Sea oil fields. Industry sponsored post graduate and post doctoral posts are available.

The research involves theoretical and experimental investigations into the flow of fluids through porous media and model networks.

Enquiries to Dr. Richard Dawe, Mineral Resources Engineering Department, Imperial College, London SW7 2BP. Tel: 01-589 5111 Ext. 1555 or 1537. (3018)A

UNIVERSITY OF PENNSYLVANIA
SCHOOL OF VETERINARY MEDICINE
CHAIR OF THE DEPARTMENT

The University of Pennsylvania is inviting applications and nominations for the Chair of the Department of Clinical Studies (Philadelphia) in the School of Veterinary Medicine.

Duties are the fostering of creative scholarship, teaching and clinical training, and leadership of the faculty not only in traditional university pursuits but also in the operation of a major urban teaching hospital. This Chair offers an unexcelled opportunity for academic leadership in clinical veterinary medicine. Nominations may be informal.

Applications should include a curriculum vitae and the names of three referees.

Communications should be addressed by Sept 30, 1984, to Dr D S Kronfeld, School of Veterinary Medicine, University of Pennsylvania, 382 West Street Road, Kennett Square, PA 19348.

The University of Pennsylvania is an equal opportunity, affirmative action employer (NW632)A

NEW YORK MEDICAL COLLEGE
DEPARTMENT OF MEDICINE
POSTDOCTORAL POSITION IN THE AREA OF MOLECULAR BIOLOGY

To study the regulation of mammalian liver cytochome P450 heme matobolism. Experience in purification, enzymology, biochemistry or related biological science desired.

Salary range: $18,000 to $20,000 depending on capability and past experience. 1 year appointment available now with possibility of 2 to 3 year extensions.

Send curriculum vitae, brief description of research interest and names of two references to: N G Ibraham, PhD, Department of Medicine, New York Medical College, Valhalla, NY 10595

(NW631)A

UNIVERSITY OF READING
SUB-DEPARTMENT OF HORTICULTURE
GRADUATE RESEARCH OFFICER

required for fixed period of one year to carry out investigations on horticultural products under the supervision of the Professor of Horticulture.

Applicants should be graduates in plant sciences, botany, horticulture or other relevant science. Salary up to £6745 p.a. (under review).

Apply quoting ref. R27A for application form to Personnel Officer, University of Reading, Whiteknights, Reading RG6 2AH.

(3013)A

THE ANIMAL VIRUS RESEARCH INSTITUTE
HEAD OF MOLECULAR BIOLOGY

Applications are invited for a new post of Head of the Division of Molecular Biology, the appointment to commence 1 October 1984. The successful candidate would also become Head of the Department of Biochemistry, and would lead a vigorous team investigating the biochemistry and genetics of several important exotic animal diseases including foot-and-mouth disease, bluetongue, and African swine fever viruses.

Candidates should have a high academic research record in the molecular biology of viruses and proven skills of leadership.

Salary in scale of £16,343-£20,794 (Grade 6 previously known as Senior Principal Scientific Officer). Sick leave and non-contributory superannuation schemes. 25 days annual holiday. House may be available for suitable married applicant. The successful applicant may qualify for financial assistance with removal expenses. The AVRI is an equal opportunity employer.

Application forms from the Secretary, Animal Virus Research Institute, Pibright, Woking, Surrey GU24 0NF. Tel: 0483-232441. Closing date for applications 10th July, 1984. (2966)A

UNIVERSITY OF WALES WELSH NATIONAL SCHOOL OF MEDICINE

DEPARTMENT OF MEDICAL BIOCHEMISTRY

RESEARCH OFFICER

Applications are invited for the post of Research Officer to work for two years on a project investigating the role of oxygen radical mediated protein modification in the pathogenesis of rheumatoid arthritis. The post is based in the School's Department of Medical Biochemistry and will involve close collaboration with the Rheumatology Unit. Candidates should have a degree in Biochemistry or a related discipline.

Commencing salary £6,310 per annum on the scale for University Research and Analogous Staff Grade 1B (£6,310 — £8,530 per annum).

Further particulars (quoting Ref. No. M6/116) available from the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff, CF4 4XN (Tel. No. (0222) 755944 Ext. 2296) to whom applications in the form of a curriculum vitae with the names and addresses of two referees should be sent no later than 3 weeks after the date of the appearance of this advertisement. (3017)A

PLANT TISSUE CULTURE

A position is available at the Tissue Culture Laboratory of a horticultural company in West Chicago, Illinois. The qualifications for the position are: MS or BS in horticulture or related area with a strong background and interest in plant tissue, cell and protoplast culture.

Send résumé to: Dr Irwin Chu, George J Ball, Inc, P O Box 335, West Chicago, IL 60185.

(NW635)A

THE UNIVERSITY COLLEGE OF WALES ABERYSTWYTH POSTDOCTORAL RESEARCH: MICROBIAL PHYSIOLOGIST

Applications are invited for a Postdoctoral post funded by the SERC Biotechnology Directorate, and concerned with biotransformations by species of Clostridium. The applicant will join an established research group led by Professor J G Morris, studying fermentation processes in anaerobic bacteria maintained in batch and continuous flow culture. Informal enquiries may be made of Dr Douglas Kell by telephoning (0970) 3111, Ext 3055.

The appointment will be for up to 3 years, depending on the starting date, and will commence not later than 1 October 1984. The salary scale is £7190 to £11615 per annum (under review).

Application forms and further particulars may be obtained from the Staffing Officer, The University College of Wales, Old College, King Street, Aberystwyth, SY23 2AX (Tel (0970) 3177, Ext 207).Completed applications to be returned as soon as possible. (3011)A

The Department of Zoology of the British Museum (Natural History), has in its charge the national collections of all recent animal groups other than the Insecta. Its pre-eminent position as a centre for research in systematic zoology springs from the immense scale and diversity of these collections (enormously rich in type and other historically important material), and their provenance, and from the special responsibilities and opportunities which derive from the Museum's national and international obligations in science.

Supported by two Deputy Keepers, the successful candidate will control and co-ordinate the work of some 96 staff, including 87 scientists, responsible for the care, maintenance and documentation of the collections in their charge, and research and the provision of identification and advisory services. Senior members of staff are authorities of international standing in their fields, and, exploiting a range of techniques, their research work is concerned principally with descriptive and revisionary taxonomy, the elucidation of phylogenetic relationships and the study of evolutionary patterns and processes.

Keeper of Zoology

As a scientist of high professional standing, the Keeper will provide academic leadership to the Department and will have the capacity to motivate a highly productive staff force to further success. By keeping abreast of current scientific developments, he/she will formulate and develop research policies and will play an important role in a 'collegiate' system of top management which, while preserving the ultimate authority of the Trustees and the Director, involves Heads of Departments in forming and sharing responsibility for policy decisions which set the course for the whole Museum.

Candidates should normally have a good honours degree or equivalent (including overseas) qualification in Zoology or an allied discipline, and experience in the development, management and direction of research programmes.

Appointment will be as Grade 6 (formerly Senior Principal Scientific Officer), with starting salary (including £1250 Inner London Weighting) £16,855 rising to £22,040. SALARIES UNDER REVIEW.

For further details and an application form (to be returned by 20 July 1984) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). **Please quote ref: S/6249.**

The Civil Service is an equal opportunity employer

British Museum (Natural History)

SPECTROSCOPIST

The California Institute of Technology is seeking an NMR Spectroscopist for the NSF Southern California Regional NMR facility, beginning in August. The position involves aiding the Manager in daily operation, NMR methods core research & instrumentation development, and collaborative projects with users. The facility has a Bruker WM-500 and a home built 200 MHZ solids spectrometer and is staffed with student operators & electronics technician. PhD in Chemistry or related discipline & research experience in NMR spectroscopy required. Must have command of theory and applications of modern NMR spectroscopy, including 2-D.

Qualified applicants are encouraged to send a résumé with salary history to Supervisor of Employment, Position No 229, Caltech, Pasadena, CA 91125.

MRC BRAIN METABOLISM UNIT
Edinburgh
Organic Chemist

The MRC Brain Metabolism Unit invites applications from suitably qualified chemists for the post of Organic Chemist with special expertise in the synthesis of neuropeptides and appropriate analogues. Candidates of immediate post-doctoral or equivalent status will be preferred. A period (minimum 3 months) of training in the peptide chemistry in the laboratory of Dr R.C. Sheppard (MRC Laboratory of Molecular Biology) may be offered to a suitable candidate who, although highly competent in organic chemistry, has no special expertise in peptide chemistry.

The person appointed will work in close association with the Molecular Biologists in the Unit who are interested in the mechanisms of synthesis, release and mechanism of action of neuropeptides in mammalian brain. The appointment will be short-term (3 years). Remuneration will be at an appropriate point on the scales for university non-clinical academic staff.

Further details can be obtained from the Director, Dr G. Fink, MRC Brain Metabolism Unit, Department of Pharmacology, 1 George Square, Edinburgh EH8 9JZ. Four copies of applications and the names and addresses of three referees to be sent to Mrs A. Milligan, Administrative Officer, MRC Brain Metabolism Unit, Department of Pharmacology, 1 George Square, Edinburgh EH8 9JZ by Friday, July 27. (2917)A

ICI

CORPORATE BIOSCIENCE GROUP

PLANT MOLECULAR BIOLOGY

POST DOCTORAL RESEARCH FELLOW AND GRADUATE RESEARCH SCIENTIST

Two vacancies have arisen in the Plant Molecular Biology Group at ICI's Runcorn Laboratories. The successful candidates will join a small team investigating plant gene structure and function. This group is part of a large molecular biology and biochemistry team with long term research goals in mammalian and plant biology.

The successful applicants will join established programmes working on the isolation and characterisation of phenylalanine-amonia lyase genes from French bean, and polygalacturonase genes from ripening tomatoes. The post-doctoral fellow is expected to have experience in cloning genomic DNA, DNA sequence analysis, s_1-mapping etc. The research scientist should have a sound practical knowledge of modern molecular biology techniques. Both positions are available immediately. The starting salary for the graduate will be minimum of £7,000 plus benefits. The position of post doctoral research fellow is initially available for a 2 year period and the starting salary will not be less than £9,500 depending upon experience.

Applications including a CV please to Miss E H Lauermann, Personnel Officer, PO Box No. 11, The Heath, Runcorn, Cheshire by 26 July, 1984. (3004)A

FERMENTATION CONSULTANT

We are a rapidly growing biotechnology firm manufacturing and selling enzymes and other process aids to the food and drink industries worldwide. Our manufacturing facilities are located in Western Europe and we are currently engaged in expanding our fermentation capacity substantially. We are seeking the services of an experienced fermentation technologist to act as consultant.

The responsibilities of this consultancy will be two-fold (1) to oversee/advise on the commissioning of our new plant and (2) to contribute technically at the pilot and production scale to the optimisation of microbial (bacterial and fungal) fermentation processes currently under development.

Application and correspondence should be submitted to the undersigned below and will be treated in strictest confidence. Keith Walesby, Bio/ Technology, 4, Little Essex Street, London, UK, WC2R 3LF.

INSTITUTE OF CANCER RESEARCH

The Institute of Cancer Research has the following technical vacancies in its Drug Development Section based at Sutton, Surrey.

RESEARCH OFFICER

The successful candidate will join a small team studying the mechanism of action and general pharmacology of novel antitumour agents. Candidates with a degree or equivalent (MIBiol) in the biological sciences, particularly in biochemistry and pharmacology, are invited to apply. Salary in range £6,204 – £8,126 p.a. plus London Allowance of £623 p.a. **Ref 301/ B/ 49.**

TECHNICIAN

The successful candidate will join a small team studying the mechanism of action and general pharmacology of novel antitumour agents. Facilities are available for further study and the successful applicant will be encouraged to exploit these. Candidates with an HNC or equivalent in the biological sciences, particularly in biochemistry and pharmacology, are invited to apply. Salary in range £5,491 – £6,436 p.a. plus London Allowance of £623 p.a. **Ref. 301/ B/ 50.**

Technician

This vacancy is for an Organic Chemistry Technician. The successful candidate will be invited to join a small multi-disciplinary group concerned with the synthesis and evaluation of quinazoline-based antifolates as potential cancer chemotherapeutic agents. Applicants should possess a degree or equivalent and preferably laboratory experience in general heterocyclic organic chemistry. Salary in range £5,491 – £6,436 p.a. plus London Allowance of £623 p.a. **Ref. 301/ B/ 51.**

Applications for any of the above posts should be sent in duplicate and giving the names, addresses and telephone numbers of two referees to* the Personnel Officer, Institute of Cancer Research, 34 Sumner Place, London, SW7 3NU, *and quoting the appropriate reference number. (3059)A

Deputy Director General

INTERNATIONAL COOPERATION

The International Center for Agricultural Research in the Dry Areas (ICARDA) with headquarters in Aleppo, Syria, invites applications for the Position of Deputy Director General – International Cooperation.

Responsibilities: Responsible directly to the Director General for:
1. Developing policies on matters relating to the Center's international relationships.
2. Establishing and strengthening collaborative links with national agricultural research and training programs in the region (Morocco and Pakistan) and where appropriate, in less developed countries elsewhere in the world.
3. Developing research and training linkages with regional and international organizations and centers and with appropriate resource institutions in advanced countries.
4. Establishing and monitoring the execution of cooperative agricultural research and training projects.
5. Supervising the regional offices of ICARDA (currently Cairo, Tunis, Amman, Beirut).
6. Assisting the Director General in contacts with Governments in the region and with donor organisations.

Qualifications:
1. Ph.D. degree in an appropriate field of agricultural research.
2. A minimum of five years in research leadership position.
3. Wide international experience and proven leadership ability.
4. A good knowledge of the Near East and North Africa region.
5. Fluent in spoken and written English essential. Knowledge of Arabic and/or French very desirable.

Conditions of appointment:
International tax-free salary based on background and experience, use of car, allowance towards housing, annual home leave, non-contributory medical insurance scheme, pension fund (TIAA-CREF in USA).
Candidates should send two copies of their curriculum vitae and names of three referees by airmail quoting reference DIR/1/84 to:

Dr. Mohamed A. Nour
Director General, ICARDA
P.O. Box 5466, Aleppo, Syria. (W1084)A

McGILL UNIVERSITY

MOLECULAR GENETICS GROUP

The Department of Biochemistry, Faculty of Medicine, McGill University is seeking three or four highly qualified individuals to form a research group with interests in the applications of molecular genetics to medically relevant topics. All positions are tenure track at the level of assistant or associate professor. Candidates should have a minimum of two years postdoctoral experience and demonstrated excellence in the application of recombinant DNA technology to animal cell systems. Each new member is expected to develop a separate, vigorous and competitive research program. Positions will be tenable after April 1, 1985.

Applicants are invited to send a complete curriculum vitae, copies of recent publications and the names of three references to Dr. C.P. Stanners, Department of Biochemistry, McGill University, 3655 Drummond Street, Montreal, Quebec, Canada H3G 1Y6.

In accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada; however others are encouraged to apply. (NW612)A

HEAD OF THE UNIT OF EQUINE PATHOLOGY AT THE ANIMAL HEALTH TRUST, NEWMARKET

A veterinary pathologist with relevant post graduate qualifications, preferably with experience in equine pathology, is required. The selected applicant will be expected to coordinate routine pathology, organise specific investigations in relation to disease incidence and undertake collaborative research. Good facilities are availble and excellent supporting staff are in post. The position offers good opportunities for an enthusiastic and progressive approach.

Salary range £13,515 to £16,925. Further details from the Director, Animal Health Trust, Balaton Lodge, Snailwell Road, Newmarket, Suffolk CB8 7DW. Applications including a detailed cv and list of publications should be submitted before August 11, 1984. (2986)A

METEOROLOGICAL OFFICE AND OXFORD UNIVERSITY

THE ROBERT HOOKE INSTITUTE FOR ATMOSPHERIC RESEARCH

SCIENTIFIC COMPUTING SPECIALIST

The Department of Atmospheric Physics, Oxford University, and the Meteorological Office, are forming a joint institute for atmospheric research to be named the Robert Hooke Institute. The work of the Institute will include satellite meteorology, atmospheric/ocean modelling for climate research and advanced instrument development and data analysis for space projects of various kinds. It will be equipped with computing facilities based on PDP 11/70 and 2 VAX 11/750 processors with image display and other advanced peripherals, and with access to mainframes at the University computing centres of Oxford, London and Manchester and to the IBM 3081/CYBER 205 at Bracknell.

The creation of the Institute provides an opening for a computer specialist interested in joining a lively scientific organization in the forefront of research using measurements from space. The successful applicant will be expected primarily to manage and develop computing facilities for the Institute's research programmes, particularly satellite meteorology, but he or she will also be encouraged to participate in the research itself. Experience with DEC hardware and software would be a considerable advantage.

The post is on the University Research Support grade 1A scale, carrying a salary in the range £7,190-£11,615 p.a. plus membership of the USS pension scheme. The appointment will commence on 16 July 1984 or as soon thereafter as is convenient.

Please apply with curriculum vitae and the names and addresses of two referees to: Dr. F.W. Taylor, Department of Atmospheric Physics, Clarendon Laboratory, Oxford OX1 3PU. (3016)A

Research Biochemist

Opportunity for a young graduate

Roche Products Limited, part of F Hoffman-La Roche Company AG, and a world leading research-based pharmaceutical company, wish to strengthen their team working on rheumatic and inflammatory diseases. This has produced an excellent career opportunity for a young biochemistry graduate to work in the Applied Biology Department.

As part of a small multi-disciplinary team, the successful candidate will be working in a modern laboratory within a new special purpose research building – offering an excellent environment in which to develop individual skills and pursue a career in advanced research.

To qualify applicants must be recent first degree graduates with an active interest in the control of cell growth and development. Exposure to the techniques used in protein purification would be particularly advantageous.

In return we offer an attractive salary and benefits to be expected of a world leading pharmaceutical company.

Please send curriculum vitae to **Mrs M.L. Clewley, Personnel Officer**, or telephone **Mrs D.M. Turner, Welwyn Garden City (07073) 28128 ext. 2129**, for an application form.

Roche Products Ltd., PO Box 8, Welwyn Garden City, Herts. AL7 3AY.

ROCHE

Wheat Breeder

Hybrid Parent Development

Nickerson RPB Limited

An experienced wheat breeder is required to initiate work on the development of parents suitable for F1 hybrid wheat production. This new challenging position requires an imaginative breeder who is willing to work on his own initiative, but closely with other breeders and breeding support teams as part of a small team. The location is at Rothwell, Lincolnshire, but candidates must be willing to travel, particularly within Europe. Knowledge of one or more European languages would be an advantage.

The successful candidate is likely to have a BSc or PhD and be currently involved in wheat breeding or closely related work. Fresh graduates need not apply.

Salary and conditions of employment will be commensurate with responsibility as you would expect of a major commercial breeding company.

Please write or telephone for an Application Form to :-

(3043)A

At the School of Sciences at the *Technische Universität Braun-schweig (Braunschweig Institute of Technology)* and at the *Gesellschaft für Biotechnologische Forschung GmbH in Braunschweig-Stöckheim (Institute for Biotechnological Research, GBF)* four positions are open for *professorships* in the fields of:

1. **Biological process engineering**
2. **Microbiology**
3. **Enzyme Technology**
4. **Genetics**

The successful applicants for each of these positions will be offered a chair as Professor at the Technische Universität Braun-schweig and then will be delegated to the GBF to become head of a department. The GBF is a large research center, supported by the Federal Government.

The heads of departments in the GBF will be expected to work in one independent research field and shape the GBF's joint research and development programmes. The TU Braunschweig expects active participation in the new programmes of biotechnology and biological process engineering.

Applicants must have a Ph.D. in Science or Engineering and should be highly qualified in one of the above noted fields, documented by a distinct research record and teaching experience.

Applications should be sent to the following address not later than August 15th, 1984:

Ber Vorsitzende der Naturwissenschaftlichen Fakultät der TU Braunschweig, Pockelsstraße 14, D-3300 Braunschweig,

who will give further information on special request.

(W1079)A

PROFESSOR OF BIOSTATISTICS

HARVARD SCHOOL OF PUBLIC HEALTH

This position is to lead and enlarge the Department of Biostatistics' current research and teaching program in statistics and the environment. Candidates should have an outstanding research record in biostatistics and an interest in problems of the environment and health. Candidates should have made significant contributions to statistical methodology. Strong teaching credentials are essential.

Applications from qualified minority and female candidates are particularly encouraged.

Candidates should send a curriculum vitae, statement of current and future interests, and the names of at least three individuals who would be willing to respond to a request for evaluation to:

Professor Donald F. Hornig
Chairman, Search Committee
Harvard School of Public Health
665 Huntington Avenue, Room 1308
Boston, Massachusetts 02115, USA

(NW639)A

The Queen's University of Belfast

CHAIR OF ANATOMY

Applications are invited for a Chair of Anatomy from 1 October 1984 or such other date as may be arranged. Salary is £19,416 per annum or, if medically or dentally qualified £20,301 per annum with contributory pension rights under FSSU or USS; an additional payment may be made by the Eastern health and Social Services Board on a sessional basis for any hospital services undertaken over and above University duties.

Further particulars may be obtained from the Personnel Officer, The Queen's University of Belfast, BT7 1NN, Northern Ireland. Closing date: 31 July 1984. (Please quote Ref 84/N.) (3084)A

WASHINGTON STATE UNIVERSITY

RESEARCH COORDINATOR

PhD in biochemistry or related areas to provide day-to-day guidance to a research group composed of post-docs, graduate students and technicians working on enzymology and molecular biology related to lipids and other natural products under the direction of P E Kolattukudy.

Send, by August 15, 1984, a complete CV and references to Director, Institute of Biological Chemistry, Washington State University, Pullman, WA 99164-6340. WSU is an Affirmative Action/Equal Opportunity employer.

(NW618)A

UNIVERSITY OF ST ANDREWS

DEPARTMENT OF CHEMISTRY

TEMPORARY LECTURESHIP IN INORGANIC CHEMISTRY

Applications are invited for a temporary lectureship in Inorganic Chemistry, tenable for one year from 1 September 1984. The lecturer will be required to give lectures at both elementary and advanced levels in the undergraduate course, to take laboratory classes, and to undertake research in collaboration with an existing research group. Applications will be particularly welcome from candidates having research experience in organometallic chemistry.

The appointment will be made in the salary range £7,190 to £8,530 per annum (under review) on the lecturer's scale, with USS benefits.

Further particulars of this post may be obtained from the Chairman of the Chemistry Department, Professor P A H Wyatt.

Applications (two copies preferably in typescript) with the names of three referees should be sent to the Establishments Officer, The University, College Gate, St Andrews, Fife KY16 9AJ to arrive not later than 18 July 1984. (2990)A

THE ANIMAL VIRUS RESEARCH INSTITUTE

HEAD OF MOLECULAR BIOLOGY

Applications are invited for a post of Head of the Division of Molecular Biology, the appointment to commence 1 October 1984. The successful candidate would also become Head of the Department of Biochemistry, and would lead a vigorous team investigating the biochemistry and genetics of several important exotic animal diseases including foot-and-mouth disease, bluetongue, and African swine fever viruses.

Candidates should have a high academic research record in the molecular biology of viruses and proven skills of leadership.

Salary in scale of £16,343-£20,794 (Grade 6 previously known as Senior Principal Scientific Officer). Sick leave and non-contributory superannuation schemes. 25 days annual holiday. House may be available for suitable married applicant. The successful applicant may qualify for financial assistance with removal expenses. The AVRI is an equal opportunity employer.

Application forms from the Secretary, Animal Virus Research Institute, Pibright, Woking, Surrey GU24 0NF. Tel: 0483-232441. Closing date for applications 10th July, 1984. (2967)A

UNIVERSITY OF GLASGOW

BIOTECHNOLOGY UNIT

POST DOCTORAL BIOCHEMIST

required to work on a 3-year project funded jointly by SERC and Pfizer Limited, to investigate the molecular biology of oxytetracycline resistance in commercial strains of Streptomyces rimosus, which produce high levels of the antibiotic.

The project will characterize the levels of expression of genes related to antibiotic resistance, study their expression signals in high and low producing strains, and investigate the biochemical mechanism of resistance. Biochemical analysis of export of antibiotic out of the cell will also be undertaken.

The position provides an opportunity to work on a commercially relevant topic, in close association with an industrial group.

Candidates with a strong biochemical background but limited recombinant DNA experience are encouraged to apply. A molecular geneticist is already in place, and the biochemist will have the opportunity to acquire recombinant DNA.

Initial salary — £7,630 — £8,530. Starting date up to 1 October 1984.

Further details and applications to Dr I S Hunter, Institute of Genetics, University of Glasgow, Church Street, Glasgow G11 5JS. Telephone 041-339 8855 ext 7112. (2989)A

UNIVERSITY OF COLORADO
DEPARTMENT OF CHEMISTRY

PROFESSIONAL RESEARCH ASSISTANTS IN BIOLOGY AND BOHYDRATE CHEMISTRY

Positions (2) are available for a plant biologist and an organic (carbohydrate) chemist to participate in the purification, isolation and characterization of biologically interesting complex carbohydrates. Applicants should have the equivalent of a Bsc or MSc in Plant Biology, Biochemistry or Chemistry. Starting salary (between $14,000 and $17,000) will depend on experience. The Univ. of Colorado is an affirmative action/equal opportunity employer.

Applications should be sent to Alan Darvill or Peter Albersheim, Dept of Chemistry, Univ of Colorado, Campus Box 215, Boulder, Colorado 80309. The applications will be evaluated August 15, 1984, [illegible]gh later applications will be [illegible]dered if the positions have not [illegible]illed. (NW627)A

POSTDOCTORAL RESEARCH ASSOCIATE

Crystallographic study of phospholipase A_2 and presynaptic neurotoxins and related complexes. Salary $18,000-22,000 depending on qualifications.
Write or telephone Paul B. Sigler, Department of Biochemistry and Molecular Biology, The University of Chicago, 920 E. 58th Street, Chicago, Il 60637. 312/ 962-1087. (NW645)A

UNIVERSITY COLLEGE CARDIFF
DEPARTMENT OF BIOCHEMISTRY

RESEARCH ASSISTANT

Applications are invited for a Research Assistantship to work with Dr N J Russell on the mechanism of membrane changes in moderately halophilic bacteria during adaptation to altered salinity. The work will involve membrane and lipid isolation/characterisation, radiochemical enzyme assays and TLC/GLC analysis. Candidates should have graduated in biochemistry, microbiology or a closely related subject.

The appointment, which is for three years, is funded by a grant from the Science and Engineering Research Council, and there will be some collaboration with the University of Ottawa. Salary RA range 1B £6,310 — £7,190 per annum. Duties to commence 1st September, 1984.

Applications (2 copies), including curriculum vitae, together with the names and addresses of two referees, should be sent to the Establishment Officer, University College, P O Box 78, Cardiff CF1 XL. Closing date 16th July, 1984. Ref: 2794. (2921)A

UNIVERSITY OF WARWICK

TEMPORARY LECTURESHIP IN VIROLOGY

Applications are invited for a temporary lectureship in the Department of Biological Sciences available for up to five years from October 1984. The successful applicant will become a member of the Virus Research Group and will be expected to undertake research in some aspect of virology and to participate in the teaching programme of the department.

The research programme of the Group is focussed on the general and molecular biology of several RNA viruses, defective particle-mediated interference, and the regulation of interferon synthesis. The position provides a career development opportunity for a young postdoctoral scientist with interests in immunological and molecular approaches to control of virus infection. Applications are invited from persons with experience in any aspect of molecular biology or cellular immunology.

The initial salary will be within the first six points of the lectureship scale: £7,190 to £9,425 pa. Further particulars and application forms from the Registrar, University of Warwick, Coventry CV4 7AL, quoting Ref No 46/A/84/0. Closing date for receipt of applications 20th July, 1984. (3001)A

UNIVERSITY OF DUBLIN
Trinity College

LECTURER IN LABORATORY ANIMAL SCIENCES/ MANAGER, WELLCOME RESEARCH ANIMAL LABORATORIES

Applications are invited for the above post at Trinity College, Dublin.
The successful candidate, who should be a veterinary surgeon, will be expected to be responsible for the management of the centralised laboratory animal facilities of the University. It is anticipated that the person appointed will become involved in research projects and in the teaching of Laboratory Animal Sciences to students.
Appointment will be made on the Lecturer scale, at a point to accord with qualifications and experience to date.

Application forms and further particulars relating to this appointment may be obtained from:
Establishment Officer
Staff Office
Trinity College
Dublin 2
Tel: 772941 ext 1775

The closing date for receipt of completed applications will be 13th July, 1984. (2985)A

CSIRO
AUSTRALIA
BIOCHEMIST
$A25,342- $A37,274
DIVISION OF PLANT INDUSTRY CANBERRA ACT

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Plant Industry is a member of the Institute of Biological Resources.

FIELD: Photosynthesis.

GENERAL: The Division conducts fundamental and applied research on problems relevant to plant biology and agricultural production. One research program is concerned with photosynthetic processes: the molecular organization and regulation of photosynthetic membranes, the mechanism and significance of C_4 pathway of carbon dioxide fixation and primary productivity in aquatic ecosystems.

DUTIES: To undertake research on the relationship between the molecular organization of chlorophyll-protein and electron transport complexes, thylakoid membrane structure and photosynthetic capacities in plants adapted to different light climates or stressed conditions. The aim is to determine what regulates and potentially limits photosynthetic yield as a prerequisite to understanding how crop production might be improved.

QUALIFICATIONS: A PhD degree or equivalent qualification in an appropriate field with relevant research experience.

TENURE: A term of three years. Australian Government superannuation benefits are available.

APPLICATIONS: Stating full personal and professional details, the names of at least two referees and quoting reference No A4715, should be directed to:

The Chief
CSIRO Division of Plant Industry
GPO Box 1600
CANBERRA ACT 2601
AUSTRALIA

By July 27, 1984.

CSIRO is an equal opportunity employer. (W1081)A

SEPARATIONS TECHNOLOGY

Amicon Wright Limited is a small, highly successful UK subsidiary of a major American group at the forefront of separations technology. Continuing growth in manufacturing and developing industrial chromatography equipment has now created a vacancy for an applications technologist.

We are looking for a person who can not only combine theoretical and practical ability, but also work in close collaboration with engineers in order to develop and evaluate new products. This is an ideal opportunity to contribute your own ideas within a lively and practical development team.

You will be qualified to degree or equivalent level with experience of high performance liquid chromatography systems, ideally within a commercial environment.

We are able to offer excellent career prospects allied to an attractive, negotiable salary, plus relocation assistance in appropriate cases. Candidates should send career details to:

Mrs S Creswick,
Amicon Wright Ltd.,
Upper Mill, Stonehouse,
Glos. GL102BJ.

(3063)A

amicon wright

Indexers

required for the

ZOOLOGICAL RECORD

Applications are invited for the post of Indexer.

Candidates should possess a degree in Zoology or an allied subject, where zoology forms part of the degree course. Some linguistic ability and/or previous indexing or abstracting experience would be an advantage.

The *Zoological Record* is an annual bibliography of the world's zoological literature, availble both in printed form and as an online database.

Duties of the posts, which are based in York, include scanning and indexing the literature to produce input for a computer based operation.

Salary starts at £5,600 for a 35 hour week. Other benefits include 4 weeks paid annual holiday, non-contributory pension and Company sick pay scheme.

Handwritten applications, giving full details of qualifications, career to date, referees, etc., should be sent, to arrive no later than 13 July, 1984, to:

Administration Manager

BIOSIS, U.K. LIMITED,

Garforth House
54 Micklegate, York, YO1 1LF.

BIOSIS

(3008)A

Scientist —

Division of Viral Products

Research on Hepatitis 'A' virus

We have a position for a post-doctoral scientist to join a small group working on the molecular and biological aspects of picorna viruses, including Hepatitis 'A' virus.

Candidates should have previous experience in viral immunology and it would be advantageous to have an interest in molecular genetics of viruses.

Salary is on a scale of £8,816 — 11,896 inclusive dependent on experience, qualifications and age. The post is supported by external funds and is available initially for 3 years.

For further details please contact the Personnel Officer, NIBSC, Holly Hill, Hampstead, London, NW3 6RB. Tel. 01-435 2232. Informal enquiries may be made to Dr G C Schild. Please quote Ref. No. SU/ VP/ 293. (3062)A

NIBSC

National Institute for Biological Standards and Control

Department of Veterinary Pathology, University of Edinburgh and the Moredun Research Institute, Gilmerton Road, Edinburgh.

Applications are invited for the following appointments to an A.F.R.C. Linked Research Group between the Departments of Veterinary Pathology, University of Edinburgh and the Moredun Research Institute, Animal Diseases Research Association, Edinburgh. The appointments are for five years.

The research programme is concerned with fundamental studies of the sheep immune system in relation to disease mdoels of persistent viral infections of sheep. The posts are located within the University Department but there will be frequent interaction with the Institute as dictated by the research programme. The appointees will work with experienced research workers in immunology and virology.

Appointments:

Research Fellow 1A — Postdoctoral cellular immunologist for studies on the in vitro analysis of lymphocyte and accessory cell function and immune regulation in vivo within lymphoid tissue (Ref. LRG31/1). Salary £8,080 — £9,875.

Research Fellow 1A — Postdoctoral immunochemist/biochemist for biochemical characterisation of lymphocytes and accessory cell membrane glycoproteins, biochemical aspects of antigen presentation using viral polypeptides (Ref. LRG31/2). Salary £8,080 — £9,875.

Research Technician — (TG4/5) with experience in cellular immunology for studies on lymphoid cell function and monoclonal antibody work. Salary on range £5,826 — £6,898 (under review) with placement according to experience and qualifications. (Ref. LRG31/3).

Research Technician — (TG4/5) with experience of biochemistry for immunochemical work on cellular and viral antigens. Salary on range £5,826 — £6,898 (under review) with placement according to experience and qualifications. (Ref. LRG31/4).

Technical Assistant — (TG2) for general laboratory duties connected with the above research programme. Salary £4,662 — £5,151. (Ref. LRG31/5).

All appointments carry full superannuation and National Insurance benefits.

Applications (curriculum vitaes, 2 referees) for posts LRG31/1 and LRG31/2 should be sent to the Secretary to the University, Old College, South Bridge, Edinburgh, from whom further particulars can be obtained. Applications for posts LRG31/3, 4 and 5 should be sent to the Personnel Office, 63 South Bridge, Edinburgh. Informal enquiries can be made to Professor I. McConnell, Department of Veterinary Pathology, Royal (Dick) School of Veterinary Studies, Summerhall, Edinburgh. Tel 031-667 1011 ext 5322. Closing date for applications 6th July 1984.

(2910)A

TRANSGENE

TRANSGENE, an independent genetic engineering company, carries out high level research oriented towards applications of medical and industrial importance.

TRANSGENE has an opening for an experienced scientist as

HEAD OF THE FERMENTATION LABORATORY

The work will be devoted to the optimisation of fermentation process involving recombinant strains and/or cell lines.

It will require a strong interface with the research groups within the company as well as a practical understanding of aspects relevant for industrial purposes.

Therefore candidates must possess a strong background in biochemical engineering and a good expertise in fermentation and recovery development covering a range of hosts.

Salaries will be competitive and commensurate with qualification.

Knowledge of French is not necessary.

STRASBOURG is a pleasant historic town, located in the heart of Europe, very close to Germany and Switzerland.

The laboratory is located next to the University campus and enjoys close contacts with well known groups in fundamental research.

For confidential consideration, send a cv, a list of publications and indication of salary requirements to:

TRANSGÈNE S.A.
Attn J.-P. LECOCQ
11, rue de Molsheim
67000 STRASBOURG
FRANCE
Tél: (88) 22 24 90

(W1070)A

UNIVERSITY OF BRISTOL
DEPARTMENT OF BIOCHEMISTRY
GRADUATE RESEARCH ASSISTANT

Applications are invited for the post of Graduate Research Assistant to work on a SERC supported project on the molecular biology of a transposable element of Drosophila melanogaster.

The post is tenable for 3 years starting from 1st September 1984 at a starting salary of up to £6745 per annum for candidates below age 27. Deadline for applications is 15th August.

A strong background in nucleic acids and/or genetics would be advantageous.

Applicants should send a CV and two letters of reference to Dr. B. Chia, Department of Biochemistry, Bristol University, BS8 1TH. (3025)A

IMPERIAL COLLEGE
POST DOCTORAL RESEARCH IN FUSION TECHNOLOGY

Imperial College is undertaking a first technical appraisal of the potential of the densez-pinch as a fusion power source. Applications are invited from suitably qualified candidates for post-doctoral posts, initially of two years' duration, in an interdisciplinary team involving the Electrical and Mechanical Engineering and Physics departments.

Principal research areas will be:
— pulsed power technology
— radiation transport and effects
— dynamics of liquid metals
— plasma simulation

Address applications and requests for further details to: Dr S Walker, Mechanical Engineering Department, Imperial College, London, SW7 2BX. (3049)A

UNIVERSITY OF LONDON
KING'S COLLEGE LONDON
DEPARTMENT OF PLANT SCIENCES

Applications are invited for the post of
POSTDOCTORAL RESEARCH ASSOCIATE

tenable for a fixed term of two years to work on a project entitled 'The Regulation of Biosynthesis of Isoprenoids in Plant Tissue Culture' funded by the SERC (Biotechnology Directorate). Applicants should have a PhD degree in an appropriate field, and specific experience in enzyme methodology. Salary will be on the Grade 1A scale commencing at £9716 including London Allowance (scale due for revision), and the post is available from 1 October 1984.

Further details can be obtained from B V Charlwood, Department of Plant Sciences, King's College London, 68 Half Moon Lane, London SE24 9JF to whom letters of application, including a curriculum vitae and the names of two academic referees, should be sent by 16 July 1984. (3019)A

UNIVERSITY OF READING
DEPARTMENT OF BOTANY
RESEARCH OFFICER

required to work with Dr R E Longton on a British Antarctic Survey (NERC) funded project on water and temperature relations of masses from maritime Antarctic cryptogamic fellfields for a fixed period of three years from September 1984.

Starting salary £6,310 pa (under review). Possibility of registration for a higher degree.

Apply quoting ref R32A for application form and further particulars to Personnel Office, University of Reading, Whiteknights, Reading RG6 2AH. (3069)A

BIRBECK COLLEGE
UNIVERSITY OF LONDON
GEOLOGY TECHNICIAN — GRADE 2

Varied duties involving preparation for classes, use of general laboratory techniques including thin section making. Minimum qualification Diploma of Advanced Geological Techniques. Excellent working conditions. Salary scale £5,912—£6,544 (under review) inclusive of London Weighting.

Apply, stating age, qualifications and experience to Assistant Secretary (Personnel) (N) Birbeck College, Malet Street, London WC1E 7HX or telephone 01-580 6622 ext 529 for application forms. (3064)A

UNIVERSITY OF ST ANDREWS
DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY

Applications are invited from physically fit single males to work mainly overseas. The post, which is for three years, is funded by a grant from the Natural Environment Research Council Special Topics Programme for Antarctic Research and is to investigate "muscle energetics, metabolism and locomotion in Antarctic animals".

Candidates should hold a good honours degree in physiology, zoology or some other relevant biological science, and have a strong interest in comparative physiology/experimental biology. Training will be given in muscle physiology and biochemistry. Some previous experience with electronics and/or computing would be an advantage. The successful candidate will leave for the British Antarctic Survey base at Signy Island during early 1985 and return in Spring 1987.

Starting salary £6,310 per annum (under review) on the 1B scale for research staff.

Further details of this post are available from the Establishments Officer, The University, College Gate, St Andrews, Fife, KY16 9AJ, to whom applications (two copies) including a full curriculum vitae and the names of two referees should be sent to arrive not later than 20th July 1984. (3045)A

Post Doctoral, Research Scientist

Department of Haematology and Oncology

Royal Children's Hospital Melbourne, Australia

An opportunity exists to undertake a leading research role in the fields of childhood leukaemia and childhood solid tumours for a scientist with experience in this field. The research laboratory, part of the department of Clinical Haematology and Oncology undertakes the care of more than 400 children with a variety of leukaemias and solid tumours and is the paediatric centre for bone marrow transplantation and autologous bone marrow rescue. Development and research are well established in the department and a list of research activities and publications will be forwarded on request. The Royal Children's Hospital is a major Paediatric centre in Australia and very good scientific support facilities are available in virtually all disciplines including immunology and recombinant DNA technology. Joint research projects with the Walter and Eliza Hall Institute and the Ludwig Cancer Research Institute are well established. Technical help will be available and there is scope for training of doctoral fellows.

The successful candidate will be funded at the appropriate N.H. and M.R.C. scale for seniority and experience (range $A20,164.00-$A30,737.00). Funds are available for a three year appointment, however transport and removal expenses cannot be provided.

Written applications describing the candidates area of interest, expertise, the proposed research programme for the three years, a curriculum vitae and the names and addresses of at least two referees, should be addressed to Dr. H. Ekert, Department of Haematology and Oncology.

Applications close Friday, 20th July, 1984.

Dr. Barry R. Catchlove,
Chief Executive.

UNIVERSITY OF CAMBRIDGE
DEPARTMENT OF BOTANY

POSTDOCTORAL POSITIONS IN PLANT MOLECULAR BIOLOGY

Applications are invited for two postdoctoral research assistant positions to work on aspects of chloroplast molecular biology. One post, supported by the Agricultural and Food Research Council, is to work on the synthesis of components of photosystem I in higher plants. The other post, supported by the Science and Engineering Research Council, is to characterise genes for components of the cytochrome complex in higher plants. Both posts are for a period of three years from 1 October 1984. The salaries will be within the 1A Scale.

Applications with curriculum vitae and the names and addresses of two referees should be sent as soon as possible to Dr J C Gray, Department of Botany, University of Cambridge, Cambridge CB2 3EA, from whom further particulars may be obtained. (3065)A

MRC CLINICAL RESEARCH CENTRE
(NORTHWICK PARK HOSPITAL)
WATFORD ROAD, HARROW
MIDDX HA1 3UJ

TECHNICIAN

Applications are invited for the post of Technician in the section of Vascular Biology to work with a team of scientists studying the generation of actions of inflammatory mediators. This position will become available in September and the work will involve investigation of microvascular responses in animal models, study of leukocyte functions in vivo and in vitro, and radioimmunoassay of mediators. Experience with pharmacological techniques and animal handling would be an advantage.
Preliminary enquiries may be made by telephone to Dr. J. L. Gordon (01) 864 5311 Ext. 2635 or Dr. T. J. Williams (01) 405 3474 Ext. 100. Applicants should have HNC or Degree in a relevant subject. Salary will be within the range £6,114-£8,370 depending on age and experience.
Application forms may be obtained by writing to Miss J. Cottam, Personnel Section, quoting reference 136/2/1546. Closing date for applications 20th July, 1984. (3005)A

UNIVERSITY OF KEELE
DEPARTMENT OF BIOLOGICAL SCIENCES
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the above position to work with Dr J. Mills on the mechanism and regulation of ATP synthesis in chloroplasts. Experience in either membrane bioenergetics or protein purifivation techniques is desirable. This is a SERC-funded position tenable for three years (one year in the first instance) from October 1st, 1984. Salary is in the 1A range, £7190-£8080.

Application forms and further particulars are available from the Registrar, University of Keele, Keele, Staffs ST5 5DG, to whom completed applications should be lodged not later than 1st August, 1984. (3090)A

LOUGHBOROUGH UNIVERSITY OF TECHNOLOGY

Lecturer in Electrochemistry

Applications are invited for this "new blood" appointment available from 1st October 1984. New developing areas of electrochemistry have been selected for support with special reference to the electrochemistry of new materials and the development of new techniques, especially in their industrial aspects. The appointment will complement the existing applied electrochemistry group.
Salary on scale £7,190-£14,125. Application forms and further details from Paul Johnson, Establishment Officer, ref.84/31 CM. Closing date for receipt of applications 10th September, 1984. (3012)A
Loughborough Leicestershire

RESEARCH ASSOCIATE POSITION AVAILABLE

Center for Blood Diseases, University of Miami School of Medicine.

Requires PhD in Immunology with proven background of independent investigation, specifically first-author publications in the field, and experience with flow cytometric techniques, in platelet and/or macrophage immunology and cell culture. Responsibilities to include research in autoimmune hematologic disorders (platelet antibody assays, drug binding to platelets, macrophage culture and functions) and in an animal model of immune thrombocytopenia. Minimum salary — $21,000. **Send resumé and three letters of reference to Department of Medicine (R-760), University of Miami School of medicine, PO Box 016760, Miami, FL 33101. Equal Opportunity/ Affirmative Action Employer.** (NW640)A

MRC CLINICAL RESEARCH CENTRE
(Northwick Park Hospital)
Watford Road, Harrow,
Middx HA1 3UJ
TECHNICIAN

A Technician will be required in the near future to work in our division of immunological medicine on a clinical study of patients with asthma. Applicants should be capable of working alone, partially unsupervised. Qualifications required are BSc or HNC plus a current driving licence. Salary will be within the range £6114-£8370 (including London weighting) depending on age and experience. **For application form and job description, apply in writing please to Miss B Shaw, Personnel Office, quoting ref 118/2/3975. Closing date for applications, 20th July 1984.** (3080)A

NORTH EAST THAMES REGIONAL CYTOGENETICS CENTRE
Queen Elizabeth Hospital for Children
Hackney Road,

BASIC GRADE CYTOGENETICIST

Applicants must have a 1st or 2nd Class Honours Degree in Biological Sciences with preferably some experience in Clinical Cytogentics.

Appointments will be on Whitley PTA Scales for NHS Scientists. Applications by letter, including curriculum vitae and the names of two referees to the Director not later than two weeks from the appearance of this advert.

NB Previous applicants need not re-apply. (3100)A

EAST DORSET HEALTH AUTHORITY
ROYAL VICTORIA HOSPITAL
MLSO HISTOLOGY

Training post/career opportunity for experienced MLSO, Science Graduate or young person with "A" levels (Chemistry/Biology) as a medical laboratory Scientific Officer in our Histology Department. The successful candidate will be encouraged to study for the "Special Examination" in Cellular Pathology, set by the Institute of Medical Laboratory Sciences.

Salary on entry at age 21 years: £4674-£4878 when state registered: £5491-£7747.

Further details from Mr R Ellins, Senior Chief MLSO Pathology Department, Royal Victoria Hospital.

Application form and job description from Personnel Officer, Royal Victoria Hospital, Shelley Road, Bournemouth, BH1 4JG.

Closing date 12th July 1984. (3087)A

THE LONDON HOSPITAL MEDICAL COLLEGE
(University of London)
DEPARTMENT OF IMMUNOLOGY
LECTURER:

Applications are invited from Molecular Biologists with an interest in immunology/histocompatibility immunogenetics. This appointment will be funded initially by The Cancer Research Campaign of Great Britain.

The successful candidate will be expected to establish and develop a molecular biology subsection of a Cancer Research Campaign funded group already working on the biology, immuno-chemistry and molecular genetics of MHC gene products in malignancy.

Salary will be on the University of London scales at Lecturer grade, within the range £9,490 to £16,440 plus London Weighting of £807.

Applications to Professor H Festenstein, Department of Immunology, The London Hospital Medical College, Turner Street, Lond E1 2AD. (309

MRC RADIOBIOLOGY UNIT, HARWELL
TECHNICIAN — CHEMIST/BIOCHEMIST

A Technician is required to join a team investigating modifications induced in biological macromolecules by ionising radiation. The project involves the techniques of radiolysis, simple analysis and purification procedures, general physical-biochemical techniques and use of microcomputers. Qualifications required are a degree or HNC/HTEC in a relevant subject. Previous experience would be helpful but is not essential as full training will be given.

Salary, according to age and experience, on the scale £5491 to £7747 pa. The Unit is situated in pleasant rural surroundings convenient for Oxford. Hostel accommodation is available for single people.

Please send applications, together with full curriculum vitae and the names of 2 referees, to the Personnel Officer, MRC Radiobiology Unit, Harwell, Didcot, Oxon OX11 ORD. Interviews will be held in early August. Closing date July 20th. Ref EMF/PC. (3077)A

UNIVERSITY OF STRATHCLYDE
DEPARTMENT OF BIOSCIENCE AND BIOTECHNOLGY

WELLCOME LECTURESHIP IN IMMUNOLOGY

Applications are invited from candidates under 35 years of age, who do not hold a permanent appointment in a UK University for a Lectureship in Immunology, funded for up to 5 years by the Wellcome Trust, and thereafter by the University.

Candidates should possess expertise in biochemical immunology; immunogenetics or immunopharmacology and will be expected to take an active part in both undergraduate and postgraduate teaching, and to participate in and extend established research programmes. Interaction with other disciplines, especially Pharmacy and Pharmacology will be encouraged.

Candidates should submit a 500 word summary of their proposed schemes for research.

Further particulars and application forms (quote 35/84) are available from Staff Office. McCance Building, 16 Richmond Street, Glasgow, G1 1XQ.

Closing Date for Applications: 20 July 1984. (3081)A

Coláiste na hOllscoile Corcaigh
University College Cork

RESEARCH SCIENTISTS FOR BIOTECHNOLOGY PROJECTS

Applications are invited for the following postdoctoral positions in the Microbiology Department:

(1) Molecular Biologist to work on the regulation of genes involved in carbon and energy metabolism in Rhizobia during the free living and symbiotic states. Experience in either molecular biology, genetics or physiology in bacterial system(s) desirable.

(2) Microbial Geneticist to join a programme aimed at exploiting beneficial bacteria for biological control of phytopathogens. Experience in microbial genetics/recombinant DNA technology desirable to work specifically on the genetics of siderophore synthesis in gram negative bacteria.

Positions tenable for up to 2 years from 1 October 1984. Salary scale 1R £7,250 to £11,000 per annum according to qualifications and experience.

Applications enclosing Curriculum Vitae and names of three referees should be sent to Dr Fergal O'Gara, Microbiology Department, University College, Cork, Ireland. (3061)A

OSTDOCTORAL RESEARCH ASSOCIATE

Synthesis and study of competitive inhibitors of phospholipase A_2 by both biochemical and crystallographic methods. Salary $18-22,000 depending on qualifications.

Write or telephone Paul B. Sigler, Department of Biochemistry and Molecular Biology, The University of Chicago, 920 E. 58th Street, Chicago, Il 60637. 312/ 962-1087. (NW647)A

UNIVERSITY
OF WARWICK
Olfaction Research Group

POSTDOCTORAL POSITION
on
Cytochrome P-450
Monooxygenases

Unusually high levels of this enzyme have recently been discovered in olfactory epithelium. We wish to know whether the olfactory enzyme has any unusual properties in comparison with the well-studied liver enzyme; whether the enzyme plays a role in the olfactory transduction process and what role the enzyme plays in the protection of olfactory tissue from damage by air pollutants.

A strong background in enzymology and related areas is required together with an interest in the special problems of the olfactory system. The laboratory has specialised facilities for investigating the transduction mechanisms.

The post is available immediately for up to two years. Starting salary on the fourth point (£8,530) on the Research Range IA scale: £7,190 — £11,615 pa, depending on age and experience.

Written applications should include a full curriculum vitae and the names of two referees and should be sent as soon as possible to Dr G H Dodd, Department of Chemistry, University of Warwick, Coventry CV4 7AL (from whom informal enquiries may be made — phone 0203 523011 ext 2234. (3000)A

RESEARCH POSTS IN

Medicinal Chemistry
Cellular Electrophysiology
Neuroimmunology
Neuropharmacology

Applications are invited for positions at Senior Scientist level, tenable from 1 January 1985.

The Institute will be housed in well-equipped and spacious new laboratory accommodation which is being built within the precincts of University College London, with which strong academic links will be forged. The scientific staff will be built up to 25–30 by 1987.

The Institute will embark on a programme of basic research in neurobiology, concentrating initially on mechanisms involved in nociception, with the long-term aim of developing new compounds of potential therapeutic value. Initially there will be six laboratory groups (Medicinal Chemistry, Biochemistry, Neuropharmacology, Cell Biology and Cell Culture, Immunology, Cellular Electrophysiology) which will collaborate on a range of individual projects.

Applicants for these positions should be 28–35 years old, with at least two years' post-doctoral experience. The research programme of the Institute will be interdisciplinary in its approach, and an ability to contribute original ideas and to collaborate effectively are particularly important.

Medicinal Chemistry

For this position a good knowledge of synthetic organic chemistry and an enthusiasm for active collaboration with biologists in the design and testing of new compounds are essential. Experience of working in the pharmaceutical industry would be an advantage.

Cellular Electrophysiology

This post will require the application of electrophysiological methods to the analysis of drug action at the cellular level. Candidates should have considerable experience of micro-electrode recording techniques or *in vitro* preparations, preferably with experience of patch-clamping.

Neuroimmunology

This post will entail the applications of immunological methods to the study of neurones in culture and *in situ*, as a means of investigating neuropeptides surface antigens and receptors. Previous experience in this area is less important than a strong background in biochemistry, cell biology and immunology, and an innovative approach to research.

Neuropharmacology

Expertise in electrophysiological recording methods *in vivo* and *in vitro* is required. The work will involve studying the effects of drugs on activity in specific sensory pathways in the peripheral and central nervous system.

Salary negotiable around £15,000 p.a. according to experience and assistance with relocation costs available if relevant.

Applications by 16 July 1984, including c.v. and names of two referees, to Professor H.P. Rang, FRS, Director, Sandoz Institute for Medical Research, Department of Pharmacology, University College London, Gower Street, London WC1E 6BT (Tel: 01-388 5314), from whom further information can be obtained. (2898)A

SANDOZ

SCIENTIFIC DIRECTOR

The Hellenic National Biotechnology Company "BIOHELLAS" S.A. is seeking an experienced individual to serve as its Scientific Director. Responsibilities will include co-ordination of R and D and industrial production programs as well as long range planning. The Scientific Director will work closely with the Company's Scientific Board and Managing Director and will be based in Athens. Qualifications include extensive and industrial research experience in biotechnology, chemistry or related sciences.

Interested individuals should contact:

BIOHELLAS S.A.

10, Parnithos St., 154.52 Palaio Psychiko
ATHENS, GREECE Telephone Nr.6474770-4

A.F.R.C. ANIMAL BREEDING RESEARCH ORGANISATION

EMBRYO MANIPULATION

Applications are invited for a molecular biologist/biochemist/-embryologist to join a team investigating the transfer of genes in farm animals and their subsequent expression and inheritance.

Candidates should have a first or upper second class honours degree in Biochemistry, Molecular Biology or relevant biological science preferably with experience of micro-injection of emryos or tissue culture cells. Applicants should have a Ph.D. or a minimum of two or four years relevant post graduate experience for appointment at Higher Scientific Officer or Senior Scientific Officer respectively. Salary according to qualifications and experience on the scales £7,149 to £9,561 (H.S.O.) and £8,970 to £11,476 (S.S.O.).

Applications giving full curriculum vitae and names and addresses of two referees to: The Secretary, Animal Breeding Research Organisation, Kings Buildings, West Mains Road, Edinburgh, EH9 3JQ.

The Agricultural and Food Research Council is an Equal Opportunities Employer. (3042)A

SOUTH TRENT CYTOGENETICS SERVICE
CITY HOSPITAL

SENIOR CYTOGENETICIST

£9,010-£11,649 p.a. (under review)

Candidates should have at least 4 years experience in Clinical Cytogenetics and be familiar with the full range of modern cytogenetic techniques.

Application forms and further particulars are available from the Personnel Department, Unit H.Q., City Hospital, Hucknall Road, Nottingham. NG5 1PB. Telephone (0602) 625459 (24 hour answering service).

Closing date: 20th July, 1984. (3007)A

Nottingham Health Authority

ST. BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE

DHSS DEPARTMENT OF TOXICOLOGY

LECTURER IN TOXICOLOGY

Salary Scale £8,376 – £15,311

This new post is a senior position for a graduate in a biological discipline with extensive experience in toxicology, especially in its pathological aspects.

The Lecturer will help to organise and run the scientific and educational work of the DHSS Department of Toxicology, concentrating on histo-pathological studies, and on assisting with research into pathological mechanisms of toxicity. The person appointed will be responsible both for service and investigative studies, as well as for teaching, and must have had several years experience of toxicology at a senior level.

There will be many opportunities to take part in a broad range of laboratory work, to develop new techniques and to aid the development of a growing department.

A job description may be obtained by telephoning 01-606 7404, quoting reference JR 15.

Please send a full Curriculum Vitae, (6 copies please) with the names of two referees to The Dean of The Medical College, St. Bartholomew's Hospital, West Smithfield, London EC1A 7BE.

Closing date 20th July, 1984. (2991)A

SYRACUSE UNIVERSITY

POSTDOCTORAL RESEARCH ASSOCIATE

Study of platinum antitumor drug-DNA interactions using natural DNA substrates of defined sequence. Experience in nucleic acid biophysics and/or DNA sequencing-gel electrophoresis preferred.

Curriculum vitae, three letters of reference to J C Dabrowiak, Department of Chemistry, Syracuse University, Syracuse, New York, 13210. Closing date 8/1/84. Equal opportunity affirmative action employer. (NW628)A

UNIVERSITY OF CALIFORNIA, DAVIS

PLANT VIROLOGIST

Assistant Professor of Plant Pathology, 11-month tenure-track appointment to begin on or before January 1, 1985, with 25% teaching, 75% research: to participate in a graduate course in plant virology and other courses in plant pathology; to develop original research program on etiology, epidemiology and control of virus diseases of agricultural crops; to participate in mission-oriented research, University service and advising and training of graduate students.

Applicants should have a PhD in plant pathology or a related discipline and expertise in plant virology. Send: a) curriculum vitae, b) official undergraduate and graduate transcripts, c) list of official published work with reprints, d) statement of teaching and research interests, e) names and addresses of three references to: J M Duniway, Department of Plant Pathology, University of California, Davis, CA 95616. Telephone: (916) 752-0324/0301. Closing Deadline: October 1, 1984.

The University of California is an affirmative action/equal opportunity employer (NW638)A

RESEARCH SCIENTI

Perform research and study i... lv-ing molecular and genetic immune mechanism and the regulation o these mechanisms during the aging process; Using biochemical, im-munological and dilution techniques and genetic engineering biotechnology to produce data fo various studies in aging and cancer PhD in Molecular Biology wit background in microbiology. Mus have publications in immunology.

Salary $34,000/year for 4 hours/week. Job in L.A.

Send this ad and your résumé t Job 1528, P O Box 865, Sacramen to, Calif 95804 not later tha 7/13/84. (NW630)A

UNIVERSITY OF NEWCASTLE UPON TYN

DEPARTMENT OF BIOCHEMISTRY

TEMPORARY LECTURER

Applications are invited for the pos of Temporary Lecturer tenable fro 1st October 1984 for three years in th Department of Biochemistry. Th post has been created by the award c a Lister Fellowship for a five yea period to Dr S J Yeaman.

Candidates will be considered wit research interests in any field biochemistry where appropria facilities can be made available, an an outline of plans for researc should be included with application

Salary will be at an appropria point on the Lecturers' scale: £7,1 — £14,125 per annum (with initi salary no higher than £11,615 p annum) according to age, qualif cations and experience.

Further particulars may b obtained from the Senior Assista Registrar (Establishments) The University, 6 Kensi Terrace, Newcastle upon Tyne N 7RU, with whom applications copies), together with the names a addresses of three referees should lodged not later than 9th Augu 1984. Please quote reference N. (3056)A

Derbyshire College of Higher Education

RESEARCH ASSISTANT

BIOLOGY

The post is tenable for 3 years from October 1984 to work under the direction of Dr M Greenwood on the reproductive physiology of viviparous and ovoviviparous cockroaches.

Candidates should have or expect to obtain a first or second class honours degree in a biological subject. The successful candidate will be expected to register for a higher degree.

Salary: £4,200-£4485 (under review).

Application forms and further particulars from the Staffing Officer, Derbyshire College of Higher Education, Kedleston Road, Derby DE3 1GB, telephone Derby 47181, extension 22, to whom completed forms should be returned by Friday, 13th July 1984. (3030)A

University of Cambridge AFRC Unit of Invertebrate Neurophysiology and Pharmacology

Animal Health Biology Pfizer Central Research

Post Doctoral Research Fellow Invertebrate Neuropharmacologist

Applications are invited for a postdoctoral research position to study the pharmacology of invertebrate GABA receptors. The post is funded by an SERC Co-operative Research Grant and will involve both electrophysiology (voltage clamp and patch clamp) on identified neurones and biochemical (radiolabelled ligand binding) studies. The research will be carried out in Cambridge in collaboration with neuropharmacologists from the Invertebrate Pharmacology Group at Pfizer.

Applicants should possess or be about to submit for a PhD.

The appointment will be for three years from 1st September, 1984.

Further information may be obtained from the secretary AFRC Unit of Invertebrate Neurophysiology and Pharmacology, Department of Zoology, Cambridge University, Downing Street, Cambridge CB2 3EJ, U.K.

Applications including curriculum vitae and the names of two referees should be sent to the AFRC Unit Secretary at the above address. (3101)A

CHIEF, ENDOCRINOLOGY & Research Scientist needed to lead endocrine, metabolic nutrition reference lab section; requirements: PhD in Science or related field, 3 yrs of related research, 2+ yrs supervisorial exp in a lab setting. Job site: Los Angeles; salary $43-50K/yr. Send this ad w/your CV to Job 2509, PO Box 865, Sacramento, CA 95804 before July 19 (NW641)A

POSTDOCTORAL RESEARCH ASSOCIATE

Crystallographic and biochemical study of protein/nucleic acid interactions including *trp* repressor and tRNA/synthetase complexes. Salary $18,000-20,000 depending on qualifications.

Write or telephone Paul B. Sigler, Department of Biochemistry and Molecular Biology, The University of Chicago, 920 E. 58th Street, Chicago, Il 60637. 312/962-1087. (NW646)A

IMPERIAL COLLEGE

POST-DOCTORAL RESEARCH ASSISTANT — AUTOMATICALLY GUIDED VEHICLES

A post-doctoral research assistant is required to join a multi-disciplinary group investigating various aspects of automatically guided vehicles, including the problem of real-time control of a fleet of free ranging AGV's. The work is funded by industrial research contracts, and the appointment would be initially for a period of one year.

Amongst the topics studied are vehicle to controller communications, predictive computer simulation and conflict avoidance, and vehicle location. The actual area of research would depend on the interests and experience of the successful candidate.

Applications are invited from candidates with good first degrees in engineering, physics or mathematics, and relevant PhD.

Address applications and requests for further information to: Dr S P Walker, Mechanical Engineering Dept., Imperial College, London SW7 2BX (01-589 5111 ext 2470). (3072)A

UNIVERSITY OF LONDON

BRITISH POSTGRADUATE MEDICAL FEDERATION

THE CARDIOTHORACIC INSTITUTE

RESEARCH ASSISTANT/ TECHNICIAN

Applications are invited for the above post which is available for 2¼ years for work on the biochemistry of cardiac protein turnover. Applicants should have an appropriate degree or suitable laboratory experience. In addition, experience with heart perfusion and/or amino acid analysis would be an advantage. There may be an opportunity to register for a higher degree. The post is based in London, N1.

Starting salary on the base point of the Whitley Council MLSO grade currently £5,491 plus £1,042 London Weighting. The post is superannuable.

Applications quoting reference CMB2 (with daytime telephone number, if possible) to the Secretary, Cardiothoracic Institute, Fulham Road, London SW3 6HP, to include two copies of full curriculum vitae and names and addresses and telephone numbers of two academic referees. Closing date 20 July 1984. (3052)A

ASSISTANT PROFESSORS (3)

DEPARTMENT OF SURGERY

WEST HAVEN VA

YALE MEDICAL SCHOOL

General Surgery: Applicant must have completed a fellowship in colo rectal surgery. Special interest is required in the development of an experimental surgery laboratory as part of an active clinical and investigative program in the areas of the neural and hormonal modulation of large bowel function. In addition, a strong background in endoscopic, diagnostic and therapeutic procedures is required.

General Surgery: A special interest is required in gastrointestinal and endocrine surgery as part of an active clinical and investigative program in the area of the endocrine and gastrointestinal systems. Research experience in the area of plasma peptide radio immuno assay and isolated organ perfusion systems is required. Competence in both upper and lower GI endoscopic, diagnostic and therapeutic modalities is necessary.

Vascular Surgery: Applicant must have completed a vascular surgery fellowship. A special interest is required in the pathogenesis of atherosclerosis and in particular its relationship to prostaglandic metabolism. A substantial commitment to the development of an investigative program relating to endothelial cell culture and seeding is required.

All candidates will be expected to devote 60% of their time to investigative efforts and their remaining time to clinical and teaching responsibilities. The position will require a full-time commitment to the Yale Department of Surgery at the West Haven Veterans Administration Hospital.

Submit a complete cv and detailed letters of recommendation to:

Irvin M. Modlin, M.D., Vice Chairman
Department of Surgery
Yale University School of Medicine
P.O. Box 3333
New Haven, CT 06510

Yale is an equal opportunity affirmative action employer. Application deadline is August 15, 1984. (NW643)A

PHYSICIST

M & D Technology Ltd. operates at the forefront of medical instrument technology and enjoys a worldwide reputation in the design and manufacture of Nuclear Magnetic Resonance Imagers. Working closely in association with Aberdeen University the company already employs over 30 people, mainly engineers and physicists; and further expansion is planned.

The physicist will be part of a research and development team working on new imaging techniques. This is an opportunity for a talented physicist with an interest in NMR. A good honours degree is essential and higher qualifications advantageous.

Write in confidence giving full C.V. to:

Managing Director,
M & D Technology Ltd.,
Unit 1, Whitemyres Avenue,
Aberdeen, AB2 6HQ. (3009)A

AQUATIC ZOOLOGIST

Required to join team of ecologists working on the 'Kennet and Avon Canal' and environs in Berkshire. Previous experience in the identification of freshwater invertebrates and fish survey techniques would be an advantage.

This is an MSC project, and to be eligible, applicants must have been unemployed for six months (age 18-24) or for 12 months (age 25+). CV's to J. Matthews, Kennet and Avon Canal Project, Aldermaston Wharf, Padworth, Reading RG7 4JH., by 20th July, 1984. (3035)A

MRC BRAIN METABOLISM UNIT
Edinburgh
Organic Chemist

The MRC Brain Metabolism Unit invites applications from suitably qualified chemists for the post of Organic Chemist with special expertise in the synthesis of neuropeptides and appropriate analogues. Candidates of immediate post-doctoral or equivalent status will be preferred. A period (minimum 3 months) of training in the peptide chemistry laboratory of Dr R.C. Sheppard (MRC Laboratory of Molecular Biology) may be offered to a suitable candidate who, although highly competent in organic chemistry, has no special expertise in peptide chemistry.

The person appointed will work in close association with the Molecular Biologists in the Unit who are interested in the mechanisms of synthesis, release and mechanism of action of neuropeptides in mammalian brain. The appointment will be short-term (3 years). Remuneration will be at an appropriate point on the scales for university non-clinical academic staff.

Further details can be obtained from the Director, Dr G. Fink, MRC Brain Metabolism Unit, Department of Pharmacology, 1 George Square, Edinburgh EH8 9JZ. Four copies of applications and the names and addresses of three referees to be sent to Mrs A. Milligan, Administrative Officer, MRC Brain Metabolism Unit, Department of Pharmacology, 1 George Square, Edinburgh EH8 9JZ by Friday, July 27. (3096)A

AFRC INSTITUTE OF ANIMAL PHYSIOLOGY
Babraham Cambridge CB2 4AT
HEADSHIP OF DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the post of Head of the Department in succession to Dr R M C Dawson FRS who retires in June 1984. The Greville Biochemical Laboratory was completed in 1971 and provides 2,230 m^2 of laboratory space with excellent facilities for work on farm animals. The present programme includes genetic manipulation of ruminal micro-organisms and cellular biochemistry. It is expected that the successful candidate will have an established reputation as a leader of research in some field related to molecular signalling in cells eg gene expression, cell differentiation, hormone targetting, antigen recognition, etc. Collaboration will be encouraged with other research at the Institute which includes reproductive biology, endocrinology, neuroscience, cell biology and immunology.

The appointment will be at the grade of Senior Principal Scientific Officer (£15,605–£19,317). Further information can be obtained from the Director, Dr B A Cross FRS. Applications should be sent to the Director by the 28th July 1984. (3070)A

HOWARD HUGHES MEDICAL INSTITUTE
RESEARCH ASSOCIATE/ POSTDOCTORAL FELLOW

MD or PhD sought for 8/1/84 to participate in studies on the role of insulin receptor tyrosine kinase and regulatory protein phosphorylation in insulin action. Experience preferred in the area of reconstruction of membrane proteins; cell fusion; protein chemistry or immunologic techniques.

CV and 3 references required. Salary $17,000 — $20,000/year, depending on experience.

Contact: J Avruch, Howard Hughes Medical Institute Laboratory, Diabetes Unit, Massachusetts General Hospital, Boston, MA 02114; or call: (617) 726-2874. (NW616)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE UNIVERSITY OF LONDON
DEPARTMENT OF HAEMATOLOGY
JUNIOR TECHNICIAN

Required for one year to work on a research project on iron chelators.

Salary on appropriate Whitley Council scale for Junior MLSO s, according to age and experience.

Application forms, which should be returned with the least possible delay, available from School Office, Room G650, RFHSM, Rowland Hill Street, London NW3 2PF, or telephone 794-0500 extn 4262. Please quote reference H/JT. (3034)A

ASSISTANT PROFESSOR OF PLANT PATHOLOGY UNIVERSITY OF CALIFORNIA, DAVIS
VEGETABLE PATHOLOGIST

To develop an original research program on etiology, epidemiology, and control of diseases of vegetable crops, including physiogenic diseases, and to teach graduate courses in diseases of vegetable crops and IPM. An 11-month tenure-track position available immediately, with 25% teaching and 75% research. Appointee will also participate in mission-oriented research, University service, and graduate advising/training.

Applicants should have a PhD in plant pathology or related discipline and expertise appropriate to the position. Send: a) curriculum vitae, b) official undergraduate and graduate transcripts, c) list of official published work with reprints, d) statement of teaching and research interests, e) names and addresses of three references to: R N Campbell, Department of Plant Pathology, University of California, Davis, CA 95616. Telephone: (916) 752-0314.

Closing deadline: 17 September 1984.

The University of California is an affirmative action/equal opportunity employer. (NW637)A

THE UNIVERSITY OF ASTON IN BIRMINGHAM

DEPARTMENT OF CHEMICAL ENGINEERING

RESEARCH ASSISTANT

Applications are invited for the above post to work on a study of the dynamics of a solvent extraction process at the Atomic Energy Establishment, Winfrith, Dorchester, Dorset. The work will involve computer modelling, and dynamics and control studies on pilot plant. It is sponsored by the UK Atomic Energy Authority.

The appointment will be for a period of three years and the commencing salary will be £6310 per annum. The successful candidate would be expected to register for a higher degree. Applicants should have an appropriate honours degree.

Application forms and further particulars may be obtained from the Staff Officer (quoting Ref: 615/6), University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET. Tel: 021 359 3611 Ext 4564. Closing date for the receipt of applications is 13th July 1984. (3085)A

NEWCASTLE HEALTH AUTHORITY

[illegible]ified 15

ROYAL VICTORIA INFIRMARY

DEPARTMENT OF MEDICINE

Research Medical Laboratory Scientific Officer or Research Scientific Officer (Graduate)

Applications are invited from suitably qualified persons to work on a project concerned with the immunological aspects of eye disease in collaboration with a Research Group working on autoimmune diseases under the supervision of Dr P. Kendall-Taylor, Consultant Physician, with a special interest in endocrinology, at the Royal Victoria Infirmary. Candidates *must* have a good background in biochemistry and it would be advantageous to have had previous experience in immunochemistry.

Salary Scale: M.L.S.O. (State registered) £5,491 p.a. to £7,747 p.a.
Scientific Officer (Science Graduate) £5,681 — £8,349)

Applications giving full details, and the names and addresses of two referees, should be sent to the Unit Personnel Officer, Royal Victoria Infirmary, Newcastle upon Tyne NE1 4LP, quoting Ref No. 84/39. Closing date 9 July 1984.

As an economy measure, no acknowledgements will be sent. If no communication has been received by 27 July 1984, it should be assumed that the application has been unsuccessful. (3038)A

THE MEDICAL COLLEGE OF ST BARTHOLOMEW'S HOSPITAL

DEPARTMENT OF CHEMICAL ENDOCRINOLOGY

CELL BIOLOGIST/ BIOCHEMIST

Required to work on a project studying the heterogeneity of circulating growth hormone and prolactin in patients with pituitary tumours. Previous experience in tissue culture and RIA is essential. This post is available for 2 years starting immediately. Salary range £9,010 — £9,310 p.a. plus £1,042 p.a. London Weighting.

Applications with full curriculum vitae, together with names and addresses of two referees should be addressed to The Secretary, Medical College of St Bartholomew's Hospital, West Smithfield, London, EC1A 7BE quoting reference RES 15.

Closing date: 28th June 1984. (3047)A

Technician or Junior Technician

required at the Plasma Fractionation Laboratory, Churchill Hospital, Oxford, for work on production and development of preparations from human blood plasma for the treatment of patients suffering from defects of blood clotting.

Appointment to the Technician grade requires academic qualifications equivalent to HNC, H-TEC or B.Sc. in a relevant subject together with a minimum of one year's relevant working experience.

Applicants for a Junior Technician post should have a minimum of four O-levels at grade C or higher, which must include English language, mathematics, and at least one science subject (preferably chemistry).

Salary scales (under review):

Technician £5,255 — £7,413.
Junior Technician £2,889 at age 16; incremental scale to £4,442 with additional allowance for appropriate qualifications.

Write for application form to: The Secretary, Plasma Fractionation Laboratory, Churchill Hospital, Oxford OX3 7LJ.

Closing date: 16th July, 1984. (2988)A

...ND POLYTECHNIC

...Pharmaceutical Sciences

S...nent of Pharmaceutical Chemistry

...tions are invited from persons who already have or are to achieve this summer, a good Honours degree in ...rmacy, Biochemistry, Chemistry or a related appropriate ...bject, for posts available in the following areas:

RESEARCH ASSISTANT

Salary: £4,947 – £5,649 (under review)

Plant tissue culture – the tissue culture of medicinal plants and investigation of alkaloid biogenesis in plant tissue culture. The work will be directed by Dr T H Bowen in collaboration with Dr R MacLeod (University of Newcastle).

RESEARCH STUDENT

Funded by SERC grant

Drug design/drug targetting – for cancer and for tropical diseases (the latter being within the newly-formed Tropical Diseases Chemotherapy Research Unit).

Application forms and further details of the research projects available may be obtained from the Personnel Officer, Sunderland Polytechnic, Langham Tower, Ryhope Road, Sunderland SR2 7EE or telephone (0783) 76231 ext 11.

Any informal enquiries may be made to Professor J R Brown, Head of Department, Pharmaceutical Chemistry, tel (0783) 76191 ext 40.

Closing date: 12 July 1984. (3032)A

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF ELECTRONIC AND ELECTRICAL ENGINEERING

RESEARCH ASSISTANT

Applications are invited from Physicists, Engineers or Applied Mathematicians, preferably with research experience, to assist with a project on fundamental aspects of ultrasonic wave propagation and scattering.

The project will involve both theoretical work (using both finite element and finite difference techniques) and some supporting experimental studies of wave in complex layered structures.

Applicants should have an aptitude for research and a good degree or postgraduate qualification in an appropriate subject.

Starting salary will depend upon age and experience. Applicants should send their curriculum vitae and the names of two referees immediately to: Dr Leonard Bond, Dept. Electronic and Electrical Engineering, University College London, Torrington Place, London WC1E 7JE. (3071)A

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY (UNIVERSITY OF LONDON)

PHYSICS DEPARTMENT APPLIED OPTICS GROUP

LECTURESHIP

Applications are invited for this post. The appointee will be required to teach optics at postgraduate level and to build up an active research programme as well as to teach undergraduate physics. Candidates should have research interests in experimental work on optical instrumentation and/or optical system design: candidates with expertise in related areas, such as the design and construction of integrated optical devices, are also encouraged to apply.

Salary is in the range £8376 to £15311 per annum (under review), including London Weighting.

Applications, including a curriculum vitae, list of publications and the names of three referees, should be sent to Professor T W B Kibble, Imperial College, London SW7 2BZ, to arrive not later than 31st August 1984. Further details may be obtained from Professor J C Dainty at the above address. (3020)A

CAMBRIDGE RESEARCH BIOCHEMICALS LTD

RESEARCH TECHNICIANS

required to work on the synthesis of organic compounds in the fields of peptide and nucleotide chemistry. Candidates should have a degree in chemistry or the equivalent. Experience of practical organic chemistry is essential. The position offer excellent opportunities to join a rapidly expanding biotechnology company.

Salary according to qualifications and experience.

Apply in writing to:

Dr G P Priestley
Cambridge Research Biochemicals Ltd
Button End
Harston
Cambridge CB2 5NX.

(3031)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London)

POSTDOCTORAL RESEARCH ASSISTANT

required for approximately two and a half years to work with Dr J Monjardino and Dr H C Thomas within the Departments of Physiology and Medicine supported by a grant from the MRC. Project involving the study of the molecular biology of hepatitis B virus. Applicants should have experience in nucleic acid biochemistry and preferably in mRNA isolation and characterisation.

Salary on scale Research and Analogous 1A.

Further details are available from the School Office, RFHSM, Rowland Hill Street, London NW3 2PF or telephone 01-794 0500 ext 4262. Full curriculum vitae, including the names and addresses of two referees should be submitted by 13 July 1984. Please quote reference M/RA. (2998)A

UNIVERSITY OF DUNDEE

CHAIR OF BIOCHEMISTRY

Applications are invited for the Chair of Biochemistry which will fall vacant on 1 October 1984 as a result of the resignation of Professor P B Garland to take up a senior research post in industry.

Further particulars are available from The Secretary, The University, Dundee DD1 4HN with whom applications (10 copies, or if posted overseas one copy) containing full career details, a summary of research interests, and the names of three referees should be lodged as soon as possible. Please quote reference EST/18/84. It is intended that shortlisted candidates should be interviewed in Dundee before the end of September, 1984 (J). (3046)A

MRC RADIOBIOLOGY UNIT HARWELL

RESEARCH OFFICER

There is a vacancy for a Research Officer, with a degree/HNC/HTEC in biology or genetics, in a group working on mammalian genetics with particular reference to mutagenesis. The work is varied and includes recombinant DNA work, animal genetics, cytogenetics etc. The successful candidate should preferably have at least 2 years appropriate laboratory experience, and if not, will be appointed as a Technician, with consideration later for re-grading.

Salary, according to age and experience, on the scale £6204-£8126 pa for a Research Officer and £5,491-£7747 pa for a Technician. The unit is situated in pleasant rural surroundings convenient for Oxford. Hostel accommodation is available for single people.

Please send applications, together with curriculum vitae and the names of 2 referees, to the Personnel Officer, MRC Radiobiology Unit, Harwell, Didcot, Oxon OX11 ORD. Ref. MFL/SW. (3076)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London)

GRADUATE RESEARCH STUDENT

Applications are invited ... students expecting to gradua... 1984 with at least a 2i in Pharmacology, Physiology or related subject. The successful applicant will need to be confident in the use of quantitative approach. The research (supported by MRC project grant for a research assistant) involves investigation of the electrophysiology of neuromuscular transmission in a myasthenic disorder using modern micro-electrode techniques. The study is to be undertaken jointly by the Department of Pharmacology and Neurological Science during a three year period, starting October 1984, and the applicant will be registered for a PhD.

Full curriculum vitae including the names and addresses of two referees should be sent by 13 July 1984 to the School Office, RFHSM, Rowland Hill Street, London NW3 2PF (01-794 0500 ext 4262) from ... further details may be obtained. (2995)A

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

A POSTDOCTORAL RESEARCH ASSISTANT

is required for an initial appointment of two years to work on algorithm development and computer analysis of cardiovascular signals. The project is in collaboration within the Cardiac Department, The London Hospital. The successful candidate will be expected to have a background in electrical engineering or computer science with knowledge of on-line programming.

Salary on 1A scale £7,190 – £11,615 + £1,186 LA.

Applications to Dr R Kitney, Department of Electrical Engineering, Imperial College, SW7. (3040)A

STUDENTSHIPS

UNIVERSITY OF READING

DEPARTMENT OF FOOD SCIENCE

POSTGRADUATE RESEARCH STUDENTSHIPS

Applications are invited for four postgraduate research studentships, from 1 October 1984. Two available for graduates in a relevant discipline (Food Science, Chemistry, Biochemistry, Microbiology, Psychology, etc) for research on a topic within Food Science (chemical, physical, microbiological, processing, sensory, etc). Two are AFRC CASE awards. One is to evaluate factors that may involve human food choice and to propose a generalised model of food acceptability (graduates in a discipline with a significant mathematical/statistical component, eg, Statistics, Psychology, Economics); the other is to synthesise compounds to reinforce coffee aroma and to design appropriate aroma delivery systems (Chemistry graduates).

Applications from graduates with Honours degrees (I and IIi), stating age and qualifications and naming two referees, to Professor H E Nursten, Department of Food Science, University of Reading, Whiteknights, Reading RG6 2AP. (2987)F

UNIVERSITY OF LEEDS

ASTBURY DEPARTMENT OF BIOPHYSICS

SERC RESEARCH STUDENTSHIPS

Applications are invited from candidates who hold at least an upper second class degree in biophysics, computational science, physical biochemistry, physics or chemistry, or a suitable combination, for two research students tenable from October 1984.

1. A CASE studentship in collaboration with the Hannah Dairy Research Institute for studies by X-ray crystallography, computer graphics and spectroscopy on the 3-dimensional structure and function of the milk protein β-lactoglobulin.

2. An Information Technology studentship to develop computer graphics as a means of display of molecular structure and molecular interactions and in the design of molecules that might act as enzyme inhibitors for potential use as drugs.

Applicants must satisfy the SERC residential requirements.

Applications must include a Curriculum Vitae and the names and addresses of two referees and should be made as soon as possible and at the latest by 15 July to Professor A C T North, Astbury Department of Biophysics, University of Leeds, Leeds LS2 9JT. Telephone: (0532) 431751 ext 6130. (3086)F

UNIVERSITY OF CAMBRIDGE AND MEDICAL RESEARCH COUNCIL

POSTGRADUATE STUDENTSHIP

Applications are invited from graduates who have a First or Upper Second Honours Degree in Biochemistry, for an MRC postgraduate studentship, tenable for 3 years from October 1984.

The topic for research will be the regulation of renal and hepatic hydroxylation reactions in the vitamin D steroid endocrine system which controls cell calcium transport. This project is part of a long-term study into the molecular function of vitamin D.

Applications including the names of two referees, a curriculum vitae, and a telephone number where the applicant can be contacted, should be sent immediately to the Dunn Nutritional Laboratory, Milton Road, Cambridge CB4 1XJ. Telephone: (0223) 63356. Ref. DF/2. (3014)F

UNIVERSITY OF EAST ANGLIA

SCHOOL OF CHEMICAL SCIENCES

RESEARCH STUDENTSHIPS IN CHEMISTRY

The following SERC CASE studentships leading to the degree of PhD are available from 1st October, 1984.

1. Preparation and characterisation of water soluble shift reagents for ^{23}Na and ^{39}K and their application to cation transport in biological systems. (Dr R B Homer and AFRC Food Research Institute, Norwich).

2. Magnetic and optical properties of haemoproteins, especially peroxidases (Dr A J Thomson and Unilver, Port Sunlight).

Applicants must hold or expect to gain at least a II(i) degree in Chemistry and should send a curriculum vitae, including the names and addresses of two referees, to the person named at the School of Chemical Sciences, University of East Anglia, Norwich NR4 7TJ. (3068)F

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF GENETICS

An NERC RESEARCH STUDENTSHIP

is available starting October 1984 to investigate the genetics and physiology of tolerance to toxic heavy metals in bacteria from polluted aquatic environments.

The project will be supervised by Professor D A Ritchie and Dr P Strike, and would be suitable for graduates with a first or upper second class degree in Genetics, Microbiology, Biochemistry or a related biological science.

Gene-cloning techniques would be an important component of this study. Further information is available from Professor D A Ritchie (051-709 6022 ext 3114), and applications should be sent as soon as possible to: The Registrar, The University, PO Box 147, Liverpool L69 3BX. Quote Ref: RV/552/N. (2993)F

UNIVERSITY COLLEGE LONDON

RESEARCH STUDENTSHIPS

Two SERC Research Studentships leading to PhDs will be available for three years from October 1984 in the Department of Chemical and Biochemical Engineering on the following topics:

1 The use of immobilised cells for biochemical conversions of reactants dissolved in water-immiscible solvents (supervisor Prof M D Lilly).

2 The recovery and processing of rDNA polypeptide products from an aggregated form in E coli (supervisor Dr N M Fish).

Graduates in biochemistry, microbiology, biophysics, chemistry (protein chemistry), biochemical and chemical engineering interested in these topics should apply, and include a full curriculum vitae, to the appropriate supervisor in the Department of Chemical and Biochemical Engineering, University College London, Torrington Place, London WC1E 7JE. (3094)F

STUDENTSHIPS

Southampton THE UNIVERSITY

Department of Biology

SERC RESEARCH STUDENTSHIP

Research in taxonomic databases

A studentship is available from 1st October 1984, for a graduate biologist to carry out research with Dr R J White and Dr F A Bisby on the application of computer databases in plant taxonomy. The project, will involve both conventional taxonomic practice and the use of computer methods currently being developed. The person appointed will be required to register for a higher degree. **Applicants, who should hold or expect to obtain a good honours degree, should write as soon as possible enclosing a curriculum vitae and the names and addresses of two referees to Dr R J White, Biology Department, Building 44, The University, Highfield, Southampton SO9 5NH, from whom further information may be obtained if required.** (3033)F

UNIVERSITY OF LONDON THE SCHOOL OF PHARMACY

TOXICOLOGY UNIT

SERC/CASE STUDENTSHIP

A SERC/CASE Studentship in collaboration with Imperial Chemical Industries is available from October 1984 leading to a Phd for research into the mechanisms of toxicity of chemicals and anti-cancer drugs. Applicants should possess or expect to obtain a good honours degree in Biochemistry or a related discipline.

Applications, including curriculum vitae and names of two referees should be sent by 16 July 1984 to: Dr G M Cohen, Toxicology Unit, Dept of Pharmacology, The School of Pharmacy, 29/39 Brunswick Square, London WC1N 1AX. (3021)F

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE

(University of London)
Rowland Hill Street,
London NW3 2PF

Applications are invited for an

SERC STUDENTSHIP

to work on "Biophysical studies of cell membranes" under the supervision of Professor D Chapman. The project will involve the use of various spectroscopic techniques including laser flash photolysis and infrared spectroscopy. A good honours degree in biophysics, biochemistry or chemistry is required.

Applications together with names and addresses of 2 referees should be sent to Professor D Chapman, Department of Biochemistry and Chemistry, Royal Free Hospital School of Medicine, Rowland Hill Street, London NW3 2PF by 13 July 1984. (2997)F

UNIVERSITY OF BIRMINGHAM

CENTRE FOR RUSSIAN AND EAST EUROPEAN STUDIES

CONVERSION COURSE FOR ENGINEERS AND SCIENTISTS

The Joint Committee of SERC/-ESRC has allocated a studentship for engineers and scientists who wish to extend their current interests into a social science field covered in the postgraduate training programme of the Centre for Russian and East European Studies. The coursework components include Russian language and Soviet studies.

The minimum qualification required for acceptance is normally a good second-class honours degree or equivalent in engineering, science or an applied science. Students graduating this year may also apply.

For further particulars and application forms please contact the Centre Secretary as soon as possible, by letter or telephone, at the Centre of Russian and East European Studies, University of Birmingham, P O Box 363, Birmingham B15 2TT, (021-472 1301 ext 2124). Please quote reference CCSS/Nl. (3048)F

ROYAL HOLLOWAY COLLEGE UNIVERSITY OF LONDON

SERC CASE STUDENTSHIPS

Applications are invited for two Science & Engineering Research Council CASE awards. (1) Physics — Project title; Microstructure of Dense Plasmas. Co-operating Body; Culham Laboratory, UKAEA. (2) Zoology — Project title; The Development of the Blood Fluke Sanguinicola inermis in Carp. Co-operating Body; Thames Water.

Applicants should be Physicists or Biologists/Zoologists who have achieved or expect to achieve, at least Upper Second Class Honours.

Details are available from the Registrar, Royal Holloway College, Egham Hill, Surrey TW20 0EX, to whom CV's and the names and addresses of two referees should be sent. (3074)F

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF MEDICAL CELL BIOLOGY

Applications are invited for a

RESEARCH STUDENTSHIP

tenable for 3 years commencing October 1984.

The project will be concerned with the uptake and intracellular processing of cell surface receptors and is part of a programme studying selective drug targetting. Techniques employed will include tissue culture, monoclonal antibody methods and electron microscopy.

Candidates should hold a first or good upper second class degree. They should apply in writing including the names of two referees to The Registrar, The University, PO Box 147, Liverpool L69 3BX. Quote Ref: RV/550/N. (2992)F

THE FOOD RESEARCH INSTITUTE

CHEMISTRY AND BIOCHEMISTRY DIVISION

SERC CASE STUDENTSHIP
Oxidative Stability of Lipids

Applications are invited for a SERC CASE Studentship tenable at the Food Research Institute and at the University of East Anglia's School of Biological Sciences to study the factors that limit the stability of commercially important fats towards oxidative degradation.

The project will involve the use of HPLC, GC, NMR and mass spectrometry to characterise and quantify the components in these fats that control oxidative stability and will also involve working for a part of the time at the Unilever Research Laboratory at Sharnbrook, Bedfordshire.

Candidates should hold, or expect to obtain, a First or Upper Second Class Honours Degree in Chemistry, Biochemistry or a related scientific subject.

Applications giving full cv and the names of two referees should be sent to: Dr H W-S Chan, Chemistry and Biochemistry Division, Food Research Institute, Colney Lane, Norwich NR4 7UA, by 12th July 1984.

We are equal opportunities employers. (3003)F

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF PHYSIOLOGY

RESEARCH STUDENTSHIPS

A three year MRC Studentship and an SERC CASE Studentship are available from 1st October 1984. The MRC studentship concerns the properties of primary afferent neurones innervating cranial blood vessels, the meninges and their possible involvement in migraine headache. The project will involve electrophysiological and histological techniques, and is under the supervision of Professor D I Wallis.

The SERC CASE studentship is concerned with the characterisation of 5-HT receptors in the CNS using electrophysiological methods in vivo, and is under the supervision of Dr M H T Roberts.

Applicants should possess, or expect to obtain a First or Upper Second Class Degree in Physiology, Pharmacology or some other appropriate subject.

Those interested should write as soon as possible to Professor D I Wallis or Dr M H T Roberts, Department of Physiology, University College, P O Box 78, Cardiff, CF1 1XL. Ref: 2798. (2940)F

INSTITUTE OF CANCER RESEARCH and ROYAL MARSDEN HOSPITAL

Sutton, Surrey

MRC STUDENTSHIP IN PHYSICS AS APPLIED TO MEDICINE

An MRC Research Studentship in Physics is available for the 1984/8 session, tenable for up to three years full-time study, leading, normally, to a PhD degree of the University of London.

The project will involve the development of high count rate detectors for improved medical imaging with particular application to the monitoring of therapy with radionuclides. The Physics Department has good electronic and mechanical workshops and extensive computing facilities and there is an active and growing research programme being carried out in the applications of Physics to Medicine.

Applications from candidates who hold or expect to gain a first or upper second class honours degree or a master's degree in Physics should be sent, together with a curriculum vitae and the names and addresses of two referees, to the Deputy Dean, Institute of Cancer Research, Block D, Clifton Avenue, Sutton, Surrey SM2 5PX (Tel: 01-643 8901, ext 296) as soon as possible. (3060)F

SCOTTISH CROP RESEARCH INSTITUTE

Invergowrie, Dundee DD2

RE-ADVERTISEMENT

(Previous candidates need not apply)

AFRC RESEARCH STUDENTSHIP IN PLANT VIROLOGY

Applications are invited for an Agricultural and Food Research Council studentship tenable for three years from October 1984 at the Scottish Crop Research Institute for research leading to a higher degree.

The project concerns the structure, antigenicity and properties of the particle protein of nepoviruses. The work will form part of a research programme on nepoviruses, which are important group of nematode transmitted plant viruses.

Applicants should hold a first or upper second class Honours degree in biochemistry, molecular biology or other relevant biological science.

Further details and application forms may be obtained from the Personnel Officer, Scottish Crop Research Instutute, Invergowrie, Dundee DD2 5DA. The closing date for applications is 20 July, 1984.

"The Institute is an Equal Opportunities Employer". (3091)F

DEPARTMENT OF BOTANY

RESEARCH STUDENTSHIP IN PLANT MOLECULAR BIOLOGY

Applications are invited for an SERC biotechnology Directorate Research Studentship to work on the characterisation of genes for ferredoxin and plastocyanin in higher plants. The studentship is tenable for three years from 1 October 1984. Applicants should possess a first or upper second class degree in a relevant biological subject.

Applications with curriculum vitae and the names and addresses of two referees should be sent as soon as possible to Dr J C Gray, Department of Botany, University of Cambridge, Cambridge CB2 3EA
(3066)F

OXFORD UNIVERSITY

Studentships in Atmospheric and Ocean Physics and Planetary Science

Two CASE studentships are available to read for the degree of Doctor of Philosophy (D.Phil.) commencing 1 October 1984.

Ship and Satellite Measurements of the Ocean Temperature: An infrared instrument of new design is to be built at Oxford and mounted on a ship of the British Antarctic Survey. During an eight-month voyage to the south polar cap, measurements will be made from the ship and from satellites as part of a study of ocean-atmospheric heat exchange and its role in the global climate. An NERC studentship is available to support an experimental physicist of robust constitution to participate in the project.

Dynamics of the Atmosphere of Jupiter: The Geophysical Fluid Dynamics Laboratory at the Meteorological Office is studying dynamical phenomena in the atmosphere of Jupiter by theoretical models and laboratory experiments. The Atmospheric Physics Department at Oxford is participating in the NASA Galileo Jupiter Orbiter mission to make spectral images of the atmosphere from which the structure and dynamics can be deduced. An SERC studentship is available for a physicist or applied mathematician to work on common aspects.

In each case applicants should hold or expect soon to gain a first degree of at least upper second class standard.

Please write to Dr. F. W. Taylor, Department of Atmospheric Physics, Clarendon Laboratory, Oxford OX1 3PU, with the names and addresses of two academic referees and a curriculum vitae.

FELLOWSHIPS

E M B O
European Molecular Biology Organization
LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY
AUTUMN 1984 AWARDS
Next deadline: August 15, 1984

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligibile a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country. Long term fellowships are awarded initially for one year, but depending on a review of progress, they be renewed for a second year. In cases of exceptional scientific merit renewal for a third year is possible. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is August 15, 1984. Successful candidates will be notified of their awards immediately after the meeting of the selection committee, which is on October 29, 1984.

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F.R. Germany.

(W1016)E

MONASH UNIVERSITY
Melbourne, Australia

POSTDOCTORAL FELLOWSHIPS

Monash University is offering a number of Postdoctoral Fellowship positions commencing in 1985 and tenable for up to two years in any department of the University. Fellows will be expected to collaborate in their research with a member of the University staff.

Intending applicants should contact the Chairman of the Department in which they wish to work to discuss possible areas of mutual research interest.

Appointments will be in the Research Fellow Grade I range ($A20,991 — $23,436), but an appointment at Research Fellow Grade II level ($A24,353 — $31,994) may be considered in exceptional circumstances. Reference No 90162.

Applications will only be accepted on the official Application Form. This and other details are available from the Registrar, Mr J D Butchart, Monash University, Clayton, Victoria 3168, Australia. Applications close 28 September 1984.

An Equal Opportunity Employer.

(W1091)E

MASSEY UNIVERSITY
Palmerston North, New Zealand

DEPARTMENT OF ANIMAL SCIENCE

POSTDOCTORAL RESEARCH FELLOWSHIP IN PIG NUTRITION

Applications are invited for the above position funded by the New Zealand Pork Industry Board to work on an applied aspect of pig nutrition. Research experience in pig nutrition is essential and a particular interest in the nutrition of the young growing pig desirable.

The appointment is available from 1st October 1984 or soon after and will be for an initial period of one year. Remuneration will be NZ$21,600 per annum inclusive of an allowance of up to NZ$3,000 for fares.

Further details of the University, together with conditions of appointment, may be obtained from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF; or from the Registrar of the University with whom applications close on 3 August 1984.

(W1083)E

UNIVERSITY OF SURREY
AERE HARWELL

EXPLOITATION OF IMMOBILISED ANIMAL CELLS

Applications are invited for a postdoctoral research fellowship to study the effects of immobilisation on cultured animal cells. This work will be carried out at the University of Surrey as part of a larger programme funded by the Department of Trade and Industry.

The work will involve the culture of mammalian cells with particular emphasis on the design of suitable reactors and the study of the physical parameters so as to optimise the performance of such systems. Factors involved in the scale up of the equipment will also be investigated.

The Fellow will form part of a multi-disciplinary team which has been involved in the immobilisation and exploitation of eukaryotic cells for a number of years. In addition, both institutions are involved in other substantial industry oriented biotechnology programmes covering cell culture and product recovery.

The successful applicant is likely to be a chemical engineer, biochemist, cell biologist, or microbiologist with postgraduate experience in the growth and handling of tissue culture cells and a desire to apply scientific methods to the solution of technological problems.

The post will be for three years and salary will be in the range £7,190 — £8,975 per annum. Superannuation under USS conditions.

Applications in the form of a curriculum vitae (3 copies) including the names and addresses of two referees should be sent to the Deputy Secretary (Personnel), University of Surrey, Guildford, Surrey GU2 5XH, by 20 July 1984 quoting reference 282/N. Further particulars of the post can be obtained by telephoning Professor R E Spier (0483 571281 ext 687) at the University. (3053)E

THE AUSTRALIAN NATIONAL UNIVERSITY

RESEARCH SCHOOL OF PHYSICAL SCIENCES

POSTDOCTORAL FELLOWSHIPS

Applications are invited from men and women who, at the time of application, have completed or expect soon to complete requirements for a PhD degree or equivalent qualification. Appointments are for two years only. They should be taken up during the first half of 1984 and may be made in any field of research of interest to the School. Departments of the School are: Applied Mathematics, Astronomy (Mount Stromlo and Siding Spring Observatories), Atomic and Molecular Physics, Engineering Physics, Mathematics, Nuclear Physics, Plasma Research Laboratory, Solid State Physics, Systems Engineering and Theoretical Physics.

Salary will be in accordance with qualifications and experience within the range: Postdoctoral Fellow Grade 1 (at a fixed point) $A21,4[illegible] — $A24,528 p.a. Current exchange rate: $A1 = 64p approx.

Grants are provided towards travel and removal. Assistance towards housing is given to an appointee from outside Canberra. Eligible appointees will be required to join the Superannuation Scheme for Australian Universities. Maternity leave is available. The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should write to the Acting Registrar of the University, GPO Box 4, Canberra ACT 2601, Australia, or the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, for further particulars before submitting applications which close on 31 July 1984.

The University is an equal opportunity employer. (3073)

THE UNIVERSITY OF LANCASTER
Department of Physics
RESEARCH FELLOWSHIP IN CONDENSED MATTER THEORY

A postdoctoral research fellowship is available for a condensed matter theorist to work on transport and scattering problems in ultra-low temperature physics. The position is for one year and the salary will be on the bottom point of the Research Range IA (£7190-£11615 - under review).

Further particulars may be obtained (quoting reference L078 from the Establishment Officer, University House, Bailrigg, Lancaster, LA1 4YW, where applications (six copies) naming three references, should be sent NOT LATER THAN 16 July 1984.

(3026)E

IMPERIAL CANCER RESEARCH FUND
Research Fellowship

to work on a collaborative project between the Royal Institution (Professor D. Phillips), Faculty of Clinical Sciences, University College (Dr. S. Brown) and the I.C.R.F. Laboratories, Lincoln's Inn Fields (Dr. I Hart). This interdisciplinary project on the role of phthalocyanines in photoradiation therapy of tumours, develop tissue culture and animal tumour model systems for evaluation uptake, selectivity of distribution and mode of action of a series of synthetic phthalocyanines. Experience in cell biology and/or pharmacology would be an advantage but suitable clinical background is also sought. The appointment is for 3 years and the work will be conducted in Dr. I Hart's laboratory at Lincoln's Inn Fields.

Salary range £8530 to £10710 plus £1250 London Weighting depending on qualifications and experience. Further details are available from the Personnel Officer, Imperial Cancer Research Fund, Lincoln's Inn Fields, W.C.2. Quote 82/84. Applications accompanied by names and addresses of three referees should be received by 18th August.

FELLOWSHIPS

[redacted]VERSITY OF SURREY — [redacted]ERE HARWELL

[redacted]OITATION OF [redacted]MOBILISED [redacted]NIMAL CELLS

Applications are invited for a

POST—DOCTORAL [redacted]ESEARCH FELLOWSHIP

study the effects of immobilisa- n on cultured animal cells. This rk will be carried out at the Aere- rwell as part of a larger pro- mme funded by the Department Trade and Industry.

The work will involve the culture of mmalian cells with particular em- asis on their immobilisation both hin and upon support matrices. e scale-up of such techniques and dies on their suitability for in- trial application will be under- en.

Fellow will form part of a multi- inary team which has been in- he immobilisation and ex- itati of eukaryotic cells for a nber years. In addition, both itutions are involved in other sub- ntial industry oriented biotechno- y programmes covering cell ture and product recovery.

The successful applicant is likely to a chemical engineer, biochemist, biologist, or microbiologist with tgraduate experience in the wth and handling of tissue culture s and a desire to apply scientific hods to the solution of technolo- l problems.

he post will be for three years and ry will be in the range £7,190 — 975 per annum. Superannuation er USS conditions.

pplications in the form of a cur- um vitae (3 copies) including the and addresses of two referees be sent to the Deputy (Personnel), University of rey, Guildford, Surrey, GU2 1, by 20 July 1984 quoting rence 281/N. Further particulars he post can be obtained by phoning Dr C Lambe (0235 24141 822) at Harwell. (3055)E

UNIVERSITY OF SURREY AERE HARWELL

EXPLOITATION OF IMMOBILISED ANIMAL CELLS

Applications are invited for a postdoctoral research fellowship to study the effects of immobilisation on cultured animal cells. This work will be carried out at the University of Surrey as part of a larger programme funded by the Department of Trade and Industry.

The work will involve the culture of mammalian cells with particular emphasis on the development of the cell biology and the nutritive medium so as to optimise the productivity of the system. This work would be expected to lead into the investigation of techniques for the downstream processing and recovery of the product.

The Fellow will form part of a multi-disciplinary team which has been involved in the immobilisation and exploitation of eukaryotic cells for a number of years. In addition, both institutions are involved in other substantial industry oriented biotechnology programmes covering cell culture and product recovery.

The successful applicant is likely to be a chemical engineer, biochemist, cell biologist, or microbiologist with postgraduate experience in the growth and handling of tissue culture cells and a desire to apply scientific methods to the solution of technological problems.

The post will be for three years and salary will be in the range £7,190 — £8,975 per annum. Superannuation under USS conditions.

Applications in the form of a curriculum vitae (3 copies) including the names and addresses of two referees should be sent to the Deputy Secretary (Personnel), University of Surrey, Guildford, Surrey GU2 5XH, by 20 July 1984 quoting reference 283/N. Further particulars of the post can be obtained by telephoning Professor R E Spier (0483 571281 ext 687) at the University. (3054)E

ASSISTANTSHIPS

UNIVERSITY OF OXFORD
Department of Theoretical Physics

POSTDOCTORAL RESEARCH ASSISTANTSHIP IN STATISTICAL AND ATOMIC THEORY
(in association with the Theoretical Physics Division, AERE Harwell)

Applications are invited for a postdoctoral Research Assistantship to work jointly in Oxford and at Harwell in areas of research of mutual interest. This temporary appointment is for one year in the first instance but normally extendable for a further period. The position is available from 1 October 1984. The salary is on the Research Staff Scale 1A, presently £7,190-£11,615 (with USS membership).

Applications with names and two referees to Professor R J Elliott, Department of Theoretical Physics, 1 Keble Road, Oxford OX1 3NP by 31 July 1984. (3082)P

UMIST

RESEARCH ASSISTANT IN PHYSIOLOGICAL PSYCHOLOGY OF VISION

Applications are invited from honours graduates in science with an interest in visual physiology for the post of Research Assistant to study stability of colour and pattern perception and cognitive performance of human observers.

The project will involve psychophysical, electrophysiological (visual evoked potential) and psychopharmacological studies, mainly on human observers, but may be extended to studies on monkeys. It can lead to higher degrees (MSc or PhD).

The appointment on this sponsored project will be initially for a period of 12 months. Salary will be according to age, qualifications and experience on the scale £6310-£8530 pa (under review).

Applications and enquiries, quoting reference OP/103, including a curriculum vitae and the names and telephone numbers of two referees, should be addressed to Professor Cronly-Dillon, Visual Sciences Lab, Department of Ophthalmic Optics, UMIST, PO Box 88, Manchester M60 1QD (tel 061-236 3311 ext 2521). (3083)A

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

OPTICS SECTION

POSTDOCTORAL RESEARCH

New research programmes in image processing using four wave mixing in photorefractive media, space-time photon correlation, astronomical image reconstruction and coupling into optical waveguides using diffractive elements have been established. There are excellent laboratory facilities for these projects.

Several postdoctoral research assistantships are expected to be available starting between October 1984 and January 1985 for periods of 1-2 years. Salary in the range £8,376 — £12,801 including London Allowance (under review).

Enquiries and applications (cv and names of two referees) to Prof J C Dainty, Blackett Laboratory, Imperial College, London SW7 2BZ before 20th July 1984. (3051)P

AWARDS

IMPERIAL COLLEGE AND THE MRC CLINICAL RESEARCH CENTRE

ORGANIC CHEMISTRY AND CLINICAL CELL BIOLOGY

MRC PARTNERSHIP AWARD

Applications are invited for an MRC partnership award leading to a PhD degree. on the synthesis and biological activity of R-glutamyl prodrugs for use in cancer chemotherapy. The research will involve the synthesis of novel organic compounds, examination of their stability and activation by enzymes and assessment of their cytotoxic activity. It will provide broad training in organic synthesis and enzymology as well as cancer studies. The project will be supervised by Dr B C Challis (Imperial College) and Dr T J Peters (Clinical Research Centre) with equal time spent at each institute.

Applications with curriculum vitae and the names of two referees should be sent to Dr B C Challis, Department of Chemistry, Imperial College, London SW7 2AY. (3050)N

MASSEY UNIVERSITY
[redacted]nerston North, New Zealand

POSTDOCTORAL FELLOWSHIPS

lications are invited for doctoral Fellowships in 1985, to unded and awarded by the ersity Grants Committee and le within Massey University.

ards may be made for one year r three years.

tions from candidates work in any department of sity will be considered, but e awards the University ittee will give priority research areas such enetic engineer- engineering,

The emolument payable will be at a rate to be determined but not exceeding the lowest step on the University scale for lecturers (currently NZ$21,600 per annum).

Applicants should have completed the requirements for the award of the degree of Doctor of Philosophy.

Application forms together with the general conditions of appointment may be obtained from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF; or from the Registrar of the University with whom applications close on 31 July 1984. (W1092)E

THE UNIVERSITY OF AUCKLAND

DEPARTMENT OF CELL BIOLOGY

RESEARCH FELLOWSHIP

A Fellowship is available for a PhD graduate to work on the effect of cyclic AMP and calcium on protein kinases in tumour cells and the control of tumour cell growth. Applicants should have a relevant background in biochemistry, cell biology, or molecular biology. An appointment will be made for one year initially with the possibility of renewal for a second year.

Further information is available from Professor R K Ralph, Department of Cell Biology, University of Auckland, Private Bag, Auckland, New Zealand. Applications will close on 27 July 1984. (W1089)E

PFIZER AWARDS — 1984

In October, 1982 Pfizer Central Research at Sandwich, Kent announced that they would make up to six new Awards annually of £1,500 each to support young scientists who had carried out meritorious research at British Universities. The research should have potential application in the search for human or animal health drugs.

The awards are made by a panel of Pfizer scientists in consultation with senior academic advisers, on the basis of work published in the two years prior to the award. The awards are NOT open to application. Each award may be renewed at the panel's discretion for a second year. The awards are for the personal use of the recipients to further their research.

The 1984 awards are:

Chemistry

Dr. G.W.J. Fleet, Dyson Perrins Laboratory, University of Oxford. *"For his enantiospecific total syntheses of shikimic acid and pseudomonic acids from carbohydrates."*

Dr. J.K.M. Sanders, University Chemical Laboratory, Cambridge. *"For his work on the application of revolutionary new NMR techniques to the determination of the preferred solution conformation of complex natural products".*

Biology

Dr. T.J. Williams, Institute of Basic Medical Sciences, Royal College of Surgeons, London. *"For his work on the interaction of mediators in the inflammatory process".*

Dr. H.J. Field, Department of Clinical Veterinary Medicine, University of Cambridge. *"For his contribution to our understanding of the pathogenesis of recurrent herpes virus infection".*

Pharmaceutical Sciences

Dr. P. York, School of Pharmacy, University of Bradford. *"For his research into the solid state properties of powders and related areas of phamaceutical technology".*

Pfizer is a worldwide, research-based company with inter-related businesses in health care, agricultural, specialty chemicals, materials science and consumer products. The Company has a major commitment at Sandwich where it employs approximately 1,500 people, over 500 of whom are engaged in new product research. (3029)N

GRANTS and SCHOLARSHIPS

CIBA FOUNDATION SYMPOSIUM BURSARY SCHEME

Aim: To enable young scientists to attend Ciba Foundation symposia and subsequently spend 4 weeks in the laboratory of one of the symposium participants.

The bursary will cover —

a) travel expenses
b) board and lodging for the duration of the bursary

Qualifications: Applicants must be aged between 25-35 years on the closing date for application, and actively engaged in research on the topic covered by the symposium of their choice.

Topics:
1 GROWTH FACTORS IN BIOLOGY AND MEDICINE
2 MELATONIN AND THE PINEAL
3 MOLECULAR BIOLOGY OF MACROPHAGE DIFFERENTIATION
4 IMMUNOLOGY OF PEPTIDES

Applications: In writing to:
The Director, The Ciba Foundation, 41 Portland Place, London W1N 4BN
including the following information:
a) Full name, address and date of birth
b) Symposium of choice (one from the above list)
c) Qualifications and short resumé of further education
d) Career history, including full list of publications
e) Details of current research and aims of future career
f) Names and addresses of two referees

Closing Date for Applications: 30 September 1984 (3022)H

APPOINTMENTS WANTED
advertise your qualities and qualifications through the most influential science weekly in the world at a special reduced cost of *50 cents a word*. (Personal Box Numbers $10.00).

SCANNING ELECTRON MICROSCOPY at MICRO 84

84 takes place at the Bloomsbury Crest Hotel in London from July 9th to 13th 1984. MICRO is the largest conference and exhibition concerned with all aspects of light and electron microscopy; and any one microscopical technique, such as SEM, can be easily seen in the context of all the other, allied techniques, available. Today, the SEM is very much a microscopist's workhorse and there is a strong SEM theme running through the whole of MICRO. Some symposia are directed specifically to SEM, others have particular lectures which are relevant to SEM, while in still others complementary techniques are discussed. The following list highlights some of these lectures.

SEM OPIMISATION
(Thursday/Friday)

The main objective of this symposium is "Getting the best out of your SEM". A series of tutorial lectures from acknowledged experts will cover the instrument, its operation, specimen preparation, image recording and image interpretation.

TUTORIALS IN MODERN ASPECTS OF MICROSCOPY
(Wednesday)

This Symposium is concerned with microscopy and analysis of solid specimens. The lectures will not only cover SEM methods for the non-expert, but also Quantitative Microscopy, Scanning Optical Microscopy, Acoustic Microscopy, and Atom Probe Analysis.

STATE OF THE ART IN TEM AND STEM
(Tuesday)

A series of tutorial lectures will deal with imaging and analysis of thin specimens. Among other things, the symposium is intended to update the knowledge of those not working directly with TEM or STEM.

ANALYSIS IN THE SEM
(Friday)

In the sessions on X-ray microanalysis and cryo-techniques a number of the presentations specifically deal with preparation of specimens, including by low temperature methods, and their analysis in SEMs.

IMAGE RECORDING
(Tuesday)

The symposium will include lectures on optimisation of scanning images, electronic processing of images, and photographic recording of images.

APPLICATION OF SEM
(Throughout MICRO)

Throughout MICRO, many of the sessions will include lectures on applications of the SEM to structural observations and microanalysis. Topics including an SEM component include: interfaces in semi-conductors; automated SEM in environmental studies; automatic SEM particle analysis in forensic science; SEM in the study of ancient materials.

EXHIBITION
(Throughout MICRO)

It is expected that more than 50 companies will be exhibiting their latest microscopes and ancillary equipment, covering the complete spectrum of instruments and techniques including, of course, full representation of SEM equipment.

Details of the MICRO 84 programme, and further information, are available from:-

The Administrator, Royal Microscopical Society, 37/38 St Clements, OXFORD OX4 1AJ. Telephone: (0865) 248768/721081

Women Scientists

The Road to Liberation

Edited by **Derek Richter**
Institute of Neurology, University of London

April 1982 £10.00 313pp ISBN 0 333 32468 4

Anyone should find these glimpses of lives in other cultures intriguing."

"Enlightening for any aspiring scientist who thinks a scientific career is a logical progression from research post to lectureship to chair." **Georgina Ferry, New Scientist**

This book draws together the personal and intellectual biographies of eleven women biomedical scientists. The individual stories are informative, fascinating, and sometimes moving, and cover cultures as diverse as those of India, Iran, USA and the USSR.
